Potash chromates begin to come in from New Caledonia. The extraction processes, as described by M. Kienlen before the Paris Chemical Society, are either of the following:—(1.) The chrome-iron ore, previously powdered by quenching, is heated for 10 hours in a reverberatory furnace with quicklime and an alkaline carbonate. The product, on being mixed with a solution of soda sulphate, and treated with sulphuric acid, yields soda chromate and sulphate, easily separated by crystallisation. (2.) M. Schwartz's method, in which alkaline sulphates are substituted for the carbonates. The ore is heated with a mixture of soda sulphate and carbonate; in the neutral chromate solution a stream of hydrochloric acid is run, which precipitates most of the sodium chloride, after which the chromate is purified by crystallisation. According to M. Friedel, sulphate of lime alone will decompose the chromite ore, but very high temperatures are necessary.—*Chemist and Druggist*.

USE OF ROBURITE IN MINES.

A conference of the Lancashire Miners' Federation was held at Wigan on July 4th, when a special report, which had been prepared by a committee appointed by the Federation to make investigations into alleged injurious effects upon the health of the miners caused by the use of roburite for shot-firing purposes in mines was brought up for consideration. This report, which is the joint production of the whole of the committee, consisting of Mr. S. Woods, the president; Mr. T. Ashton, secretary of the Federation; Mr. T. Aspinwall, and four colliers, takes the form of a criticism upon the conclusions arrived at by Messrs. H. B. Dickson, C. J.

Mounsey, and N. Hannah, who were appointed jointly by the employers and workmen engaged at the Garswood Coal and Iron Company to investigate and report upon the effect of roburite fumes on the health of the workmen. The committee appointed by the Lancashire Miners' Federation complain that the operations expressed in the report of the specialists, who are two medical practitioners and an analyst, are so shrouded in a multitude of technical scientific statements that it is difficult to discover what their conclusions really are; but the report, it is pointed out, evidently establishes the following points, namely:—

1. That the fumes of roburite, when inhaled into the system, are an exceedingly deadly poison, even in the smallest quantity.

2. That when these fumes are inhaled into the system in a coal mine they carry with them two poisonous gases, differing from each other only by a little in their harmful effect on the human system, viz., nitric oxide and carbonic oxide.

3. That roburite may be safe while kept in the sealed cartridges, but the moment they are broken and exposed to the air, the substance is so volatile and poisonous that it at once becomes a great source of danger.

4. That incomplete or partial combustion of roburite allows the deadly elements of the composition—nitrobenzine—to escape and freely mix with the air in the mine, and therefore to be breathed by the men or absorbed by contact with the skin.

5. That roburite fired in coal dust gives off a recognised quantity of carbonic oxide.

6. That in handling roburite the greatest possible care is necessary, the greatest danger is risked, and the slightest departure from this may be followed by serious results.

7. That in the cases examined of men who had worked in places through which the roburite fumes had passed, they suffered from carbonic oxide poisoning when small quantities of the gases mixed with air had been inhaled.

8. That specially-trained men only should manipulate or be entrusted with roburite.

9. That no miner would be safe in his place until all the fumes had disappeared.

10. That where roburite is used the ventilation must be perfect, with a large quantity of air, and the brattice must be kept close to the coal face.

These 10 facts, it is urged, surely fully establish the whole of the miners' contention that overhead fumes are injurious to the health of the workmen.

After some discussion, the report was unanimously adopted by the Conference, and as a result, the future use of roburite in mines for shot-firing purposes will be opposed by the workmen.—*Iron and Coal Trades Review*.

THE ALCOHOL QUESTION IN SPAIN.

A new Act dealing with the duties on alcohol came into force on the 1st July. The matter is one of general interest, because in the natural course of events it should lead to the establishment in Spain of distilleries on a large scale. At the same time it may be anticipated, owing to the want of knowledge and enterprise on the part of Spanish capitalists, that it is only foreign capitalists who would be likely to produce alcohol in Spain under conditions likely to lead to success. The following are the chief features of the new law: Foreign alcohol of any strength continues to pay an import duty of 21 pesetas per hectolitre. All alcohol produced from anything but grapes pays 25 pesetas per hectolitre, whether of foreign or home production; the foreign spirits, however, have to pay the duty on passing the Custom house, while that made in Spain does not pay duty until it leaves the distillery where it is made. Two results may be expected, one of which might be immediate, while the other might take years to show itself. The first is that alcohol will cease to be imported. There is no reason whatever, leaving want of enterprise out of account, why alcohol, either

from grain or potatoes, should be more cheaply produced out of Spain than in Spain; and as the import duty, freight, insurance, and other import expenses come to about 50 per cent. on the prime cost, it should not be expected that the import should continue. Spirits can possibly be produced here at a lower cost than in Germany or Sweden, using the same processes and under equally intelligent management. Where land and labour are cheap it is only bad cultivation and want of manure which make agricultural produce dear. Combining the growing of potatoes and Indian corn with the production of spirits on a large scale would cause all difficulties to disappear. If English capital does not take the lead in this direction, German or Belgian capital will. The requirements of Spain may be taken at an annual wholesale value of 20,000,000*l.* so that it can be seen that the business is a large one. There is also another question in connexion with this subject. Grapes grown specially for the production of alcohol, without regard to the quality required in the grapes to make wine, and dealt with properly when gathered, will give alcohol at a lower cost than that obtained from any other material, and of a much better quality; but of course ten or twelve years would be required to prepare a vineyard specially for the production of alcohol.—*Industries.*

UNIFORM NOMENCLATURE FOR MATERIALS MADE OF IRON OR STEEL AND USED ON RAILWAYS.

Dingl. Polyt. J. 272, 46—48.

The Prussian Ministry has decreed that henceforth different kinds of iron and steel are to be known and described by specified terms. A very large number of these are given divided under two headings, viz., names having reference to method of manufacture, and names which depend on the application of the material. The former are divided into six chief groups—(1) crude iron; (2) cast iron; (3) weld iron; (4) weld steel; (5) ingot-iron; and (6) ingot-steel.—A. R.

GERMAN MANUFACTURE OF TIN.

The manufacture of tins and the putting up of goods has grown to such dimensions in Germany that the French are finding great competition, and one large Nantes (France) sardine house has a branch in Strasburg. Most of the canning houses manufacture their own tins.—*Ironmonger.*

PROPOSED STEELWORKS FOR ITALY.

Italy appears about to advance another stage as a manufacturing country, for some English capitalists intend investing 100,000*l.* in erecting works for reducing the ores to be obtained from some mineral deposits, which are stated to have been discovered in a mountain only $2\frac{1}{2}$ miles from the sea in the province of Pisa. This will do away with the transport of the minerals to Swansea for reduction, and return to Italy in a metallic state, which adds two freights and a duty to the cost of reduction. These deposits are reported to consist of tin, copper, lead, and manganese. It is stated that there is also a very rich deposit of iron ore suitable for steel-making. From this latter ore the company proposes to manufacture large steel gun-forgings. This class of ordnance is now largely coming into use, and it is stated that Armstrong and Co. have not provided for the production of such forgings at their new works near Naples. The requirements will, therefore, be met by the proposed works.—*Ibid.*

FRENCH REGULATIONS FOR PREVENTING FRAUDS IN THE MANURE TRADE.

(See this Journal 1888, 143.)

The recent law respecting artificial manures provided, among other things, that suitable regulations should be published by the administration to ensure uniformity in

chemical analyses and to avoid contentions, when fertilisers are sold according to the percentage of useful constituents. Artificial manures are often purchased at the rate of so much for combined nitrogen, so much for soluble phosphoric acid, &c., and chemists know that to have comparable analyses it is almost indispensable that similar processes be followed. Consequently, with the advice of experts, the following rules have been set down:—(1) Nitrogen shall be estimated as follows: (a) In the shape of nitric acid; turn into nitrogen binoxide by ebullition with ferrous chloride, and measure the gas evolved. (b) Ammoniacal nitrogen; distil with caustic alkali in an ascension condenser, and titrate the ammonia. (c) Organic nitrogen; all nitrates having been removed, treat with either soda lime, and titrate the ammonia formed; or with sulphuric acid containing a little mercury, and estimate the ammonia sulphate by the ammonia process as above. (2) Phosphoric acid: (a) The total acid; dissolve the substance in hydrochloric acid in the presence of ammonia citrate to keep iron, alumina, and lime in solution, and estimate, after precipitation, as ammonio-magnesia phosphate, in the shape of magnesia pyrophosphate. When too much lime is present, separate it out with oxalate of ammonia. (b) Soluble phosphoric acid; macerate the specimen for a reasonable time with distilled water, and treat the filtered liquid as above. (c) Phosphate soluble in ammonia citrate; macerate for twelve hours in alkaline ammonia citrate, and treat the filtrate as has been said before. Note: In the three foregoing processes the phosphoric acid may be first precipitated with ammonia nitro-molybdate and then estimated as magnesia pyrophosphate, as has been explained. (3) Potash: (a) Estimate as perchlorate which is to be washed with alcohol, dried, and weighed. (b) With platinum; precipitate the potash with platinum chloride, wash the precipitate with alcohol, and reduce it with soda formiate; weigh the platinum black, and calculate the corresponding weight of potash. (c) As double chloride of platinum; wash the precipitate with alcohol, dry, and weigh it. Of course proper directions are also given for taking the samples to be analysed. And, finally, a scale of prices is established as follows:—For each element estimated 10 frs., and for the report 25 frs. For one fertiliser, however, whatever may be the number of elements evaluated, the cost of the whole analysis shall not exceed 50 frs. To further ensure the operation of the law, a number of experts have been appointed in all parts of France, who shall be entitled to 6 frs. for each three hours' sitting when taking samples, travelling expenses to be borne by the State.—*Chemist and Druggist.*

PRODUCTION OF SUGAR IN THE WORLD.

Stamner. Dingl. Polyt. J. 271, 266—278.

The following tables show the quantities of sugar produced and consumed in the world:—

1. SUGAR PRODUCED.

(a.) Beet Sugar in Tons.

	1887-88.	1886-87.
	Tons.	Tons.
Austro-Hungary	400,000	550,000
Germany	915,000	1,024,000
France	400,000	483,000
Russia	430,000	472,000
Belgium	93,000	91,000
Holland and other countries	60,000	50,000
Total	2,427,000	2,670,000

(b.) *Cane Sugar in Tons.*

	1887-88.	1886-87.
	Tons.	Tons.
Barbadoes	55,000	50,000
Brazil	270,000	250,000
Cuba	625,000	625,000
Demerara	100,000	130,000
Egypt	50,000	45,000
Guadeloupe	50,000	52,000
Hawaii	90,000	90,000
Jamaica	50,000	25,000
Java	390,000	360,000
Louisiana	140,000	90,000
Martinique	40,000	40,000
Mauritius	115,000	100,000
Natal and Mayotte	12,000	12,000
East Indies	50,000	50,000
Peru	40,000	40,000
Philippines	160,000	150,000
Porto Rico	70,000	80,000
Reunion	10,000	35,000
St. Croix and Antilles	45,000	45,000
Trinidad	55,000	60,000
Total	2,427,000	2,335,000
Cane and beet sugar together	4,725,000	5,005,000

II.—CONSUMPTION PER HEAD IN POUNDS (500 GRMS.)

Germany	Lb. 18'64	Spain	Lb. 7'49
Austro-Hungary	11'08	Portugal	9'00
France	22'83	England	66'57
Russia	8'64	Bulgaria	3'30
Holland	19'94	Greece	10'0
Belgium	18'32	Servia	2'94
Denmark	19'05	Turkey	4'33
Norway and Sweden ..	17'42	Switzerland	21'37
Italy	7'19	United States of North America	47'19
Roumania	3'86		

III.—SUGAR CONSUMPTION IN TONS.

	1887.	1886.
	Tons.	Tons.
England	1,179,000	1,108,000
France	423,000	425,000
Germany	445,000	430,000
Austro-Hungary	250,000	245,000
Russia	360,000	344,000
Italy	100,000	97,500

	1887.	1886.
	Tons.	Tons.
Spain	50,000	49,000
Turkey	45,000	42,500
Belgium	46,000	45,000
Holland	45,000	44,000
Norway and Sweden	44,000	42,000
Switzerland	40,000	40,000
Denmark	36,000	35,000
Portugal	16,000	15,500
Roumania	13,000	12,500
Greece	9,000	10,000
Servia	4,000	3,500
Montenegro	1,000	1,000
United States of North America	1,397,000	1,389,000
Total	4,503,000	4,376,500

—W. M.

BEET SUGAR INDUSTRY IN JAPAN.

Dingl. Polyt. J. 271, 278.

The beet sugar factory at Mombetsu, in the island of Yesso, Japan, continues to work, and has made a small profit. The beet crop has been small, and this is chiefly due to the land being split up into very small farms, the owners of which have not much intelligence or appliances for working economically. The Government, however, is helping the farmers.

Experiments have also been made at Sapporo on the growing of beet, and the roots have been found to contain 12½ per cent. of sugar. A company has been formed to start a factory there and in this the Government is a large shareholder.—W. M.

NEW AUSTRIAN PHARMACOPŒIA.

The committee appointed to prepare a new addition of the Austrian Pharmacopœia has completed its labours; the seventh edition will be published forthwith, and will come into force on January 1, 1890. The last edition was published on October 1, 1869, so that it is not surprising to find in the list of drugs and preparations introduced for the first time many which now take rank among well-established remedies. Amongst the newer remedies which find a place are antifebrin, antipyrin, cascara sagrada, lanoline, betanaphthol, oil pini pumilionis, strophanthus, thymol, and vaseline. There are altogether 578 articles in the seventh edition, which is 43 more than there were in the last. A very considerable advance is shown in that part of the work devoted to the testing of drugs and chemicals; the apparatus to be used is described, and the tests are those best designed to detect common impurities. Volumetric analysis is applied to the estimation of the strength of certain compounds, such as the mineral and dilute acids. The opium to be used in making medicinal preparations is to contain 10 per cent. of morphine, while the cinchona is to be succimbra, of 3·5 per cent. alkaloidal value. Lanoline is defined as purified wool fat containing 30 per cent. of water. Chloroform is to have a specific gravity of 1·485—1·500, so that it may contain a little alcohol or none at all, and in the latter case the article will be liable to spontaneous decomposition, while the alcoholised one will be permanent. Sulphate of quinine is to be tested by Kerner's method, the temperature of solution being fixed at 60° C. as determined by the French Commission. In galenical preparations a little attempt has been made to fix the proportion of the active ingredient of those which are toxic. A few fluid

extracts are introduced, and for the preparation of several ordinary extracts, such as aconite, belladonna, Indian hemp, male fern, and nux vomica, percolation is for the first time employed. Most of the tinctures are to be made 1 in 10, and more precise directions are given regarding pressing and filtration. It is noticeable in regard to ointments that vaseline is not employed for any one of them, but lanoline is used in making ung. hydrargyri. Lead plaster is to be made with lard and litharge. Synonyms, which hitherto have accompanied the scientific and common names of the articles, are now placed in a table at the end of the book. To take their place we have the names of the preparations used in foreign Pharmacopœias, this being perhaps the most useful and sensible addition to the Pharmacopœia, considering the frequency with which continental pharmacists are now called upon to dispense foreign prescriptions. We propose on another occasion to more fully criticise this new Pharmacopœia, especially in regard to the influence which the international scheme has had upon it.—*Chemist and Druggist*.

GERMAN SOCIETY FOR THE PROTECTION OF CHEMICAL INDUSTRY.

The annual meeting of the Society for the Protection of Chemical Industry in Germany was held in Hamburg on July 2, under the presidency of Dr. Holtz, of Berlin. The Society's report for 1888 speaks favourably of the condition of the German chemical industry in general, and points out that the extension of the combination movement has been advantageous, less through the advance in price caused by it than because it has steadied business in general and succeeded in limiting surplus production. The number of chemical works in the whole of Germany at the close of 1887 was 4,325. At the end of last year it had risen to 4,464. The aggregate of working days in the whole of these works had been 24,375,434 in 1887, and 25,100,024 in 1888, while the money paid in wages had increased from 62,710,380 m. to 65,644,013 m., or, from 765 m. to 773 m. per head. The import of raw materials from foreign countries had increased by 124,552 tons; the export of manufactured chemicals by 33,890 tons. A careful analysis of the financial results of the year's working, as shown by the balance sheets of companies, showed an average dividend of 6.20 per cent. for alkali works, 8.05 per cent. for artificial manure works, 10.89 per cent. for manufactories of pharmaceutical and technical preparations, 13.25 per cent. for explosives works, and 15.44 per cent. for coal-tar dye works. The average percentage of dividends for the entire chemical industry was 8.50 per cent.—*Ibid*.

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCES.

The French Association for the Advancement of Sciences will hold their annual meeting from August 8th to 14th, at the School of the Ponts-et-Chaussées, 28, Rue des Saints-Pères, Paris. A number of interesting papers have been announced, and among the following bearing on chemical subjects: On Quibar, by M. d'Abbadie, of the Académie de Sciences; nitro and nitroxy combinations, Professor P. Alexeyeff, of Kief, Russia; carbon and spectroscopy, by pharmacist P. van Assche, of Rouen; starchy adulterations of pepper, M. G. Bertèche, of Valenciennes; ozone, Professors Bichat and Guntz, of the Nancy Faculty of Sciences; the photometry of incandescent lamps, and a standard for actinometers, Professor A. Crova, of the Montpellier Faculty of Sciences; on ammonia protoxide, on hydrogen protonitride, and on the acid S_2O_2 , by Professor Mauméné, of the Lyons Free Faculty of Sciences; the Eiffel Tower meteorological observatory, anemometers and anemoscopes, self-registering galvanometers, by M. Richard; electrodynamics and the motion of planets, spectroscopy of the ultra-red and ultra-violet parts of the spectrum, by Professor Zenger, of the Prague Polytechnic School. Some 18,000 frs. have been this year granted by the association to aid various researches, none of which, however, have reference to chemistry.—*Ibid*.

SENEGAL CASTOR OIL.

According to a suggestion made by pharmacist Castaing, of the French Navy, Senegal planters have commenced cultivating castor beans for export to Marseilles. So far, they have found the crop more remunerative than pea-nuts, which are produced at very low prices in the Levant and the East Indies. By the way, the quantity of castor beans received at Marseilles has considerably increased of late. In 1877 the imports amounted to 3,190 cwt. and to 67,980 in 1879, while in 1881 they rose to 181,000 cwt. Nevertheless, the demand has kept up with the supply, because new uses have been found for the oil. Perfumers consider it an excellent pomade basis; soapmakers highly appreciate it; and considerable quantities are used by machinists for lubricating, and dyers for Turkey-red. The consequence is that only an insignificant percentage, but, of course, the finest quality, of the oil is kept for pharmaceutical purposes.—*Ibid*.

IMPORTANT LEGAL DECISION.

A very important decision in commercial law has just been given by Lord Trayner in the Glasgow Court of Session. The pursuers were the Seville Sulphur and Copper Company, and the defenders Thomson, Dickie, and Co., marine insurance brokers, both of Glasgow. A cargo of pyrites, which had been insured by the defenders for the pursuers, had been lost, and a claim was made for over 6,000l. The policy had been underwritten by 13 underwriters. Three of these paid the loss claimed, but 10 had become insolvent, and only a moiety of the sum for which they were liable had been recovered from their estates. In these circumstances, the pursuers charged their brokers with carelessness in their selection of underwriters, and claimed upon them to make good the loss. They pleaded the exercise of due caution, and non-liability in consequence. The judge decided in favour of the defenders.—*Ironmonger*.

MERCHANDISE MARKS ACT (1887) AMENDMENT.

The following Bill to amend the Merchandise Marks Act, 1887, has been introduced into the House of Commons by Mr. Broadhurst, the Hon. Bernard Coleridge, and Mr. Fenwick:—

1. This Act may be cited as the Merchandise Marks Amendment Act, 1889, and shall be read and construed with the Merchandise Marks Act, 1887, as one Act.
2. All goods of foreign manufacture imported into this country shall be plainly and distinctly marked with the names of the country and place in which such goods have been manufactured. Where it is impossible to place such names on the goods themselves, all parcels or packages, of whatever size or quantity, shall bear on the cover or thing in, on, or with which any such goods are sold or intended to be sold or offered for sale, the names of the country and place in which such goods have been manufactured.
3. All goods manufactured in Great Britain and Ireland shall be plainly and distinctly marked with the name of the manufacturer and the name of the town in which such goods have been manufactured. Where it is impossible to place such names on the goods themselves, all parcels or packages, of whatever size or quantity, shall bear on the cover or thing in, on, or with which any such goods are sold or intended to be sold or offered for sale, the name of the manufacturer and the name of the town in which such goods have been manufactured.
4. In cases where machinery has entered into competition with skilled labour in the manufacture of goods, all such machine-made goods shall be marked as such.
5. Every mark or name placed on any goods or on any cover or thing in, on, or with which any goods are sold, or intended to be sold or offered for sale, shall be deemed to

be classed as manganese ores; the remainder as mangani-ferous iron ores. Of the mangani-ferous iron ores 11,462 tons, averaging 11 per cent. of manganese, and 189,574 tons, averaging 4 per cent. of manganese, were from the Colby mine, Michigan. In addition to the above, some 60,000 tons of argenti-ferous manganese ores, valued at 10 dols. a ton, chiefly for the silver contained in them, were produced in the Rocky Mountain region.

Aluminium.

The past year was more promising than ever before for the production of cheap aluminium. The production of metallic aluminium as an industry distinct from the production of alloys began towards the close of the year, and 500 pounds had been made up to December 31; the production of 3,000 pounds since then indicates that the industry may continue. The exact amount of alloys produced by the Cowles process has not been furnished, but was not markedly different from the product of 1887, when 18,000 pounds of aluminium contained in bronze and ferro-aluminium were produced. The price for metallic aluminium declined to as low as 4.50 dols. per pound for less favoured brands.

Platinum.

Including the platinum and iridium separated from gold by the assay offices and that saved in placer gold mining, the product was about 500 ounces, valued at 2,000 dols.

FUELS.

Coke.

The production of coke in the United States in 1888 was 8,527,560 tons, valued at about 14,000,000 dols. Pennsylvania produced by far the largest amount, the Connellsville region alone producing 4,955,553 tons; West Virginia, 528,533 tons; Alabama, 518,511 tons; Tennessee, 385,693 tons; and Virginia, 149,099 tons.

Petroleum.

The product of petroleum in the United States in 1888 was 27,346,018 barrels (of 42 gallons each), valued at about 24,598,559 dols. Of this amount Pennsylvania produced 16,491,083 barrels; Ohio, 10,010,868 barrels; West Virginia, 119,448 barrels; California, 704,619 barrels; and other States 20,000 barrels.

MISCELLANEOUS.

Cement.

The amount of cement produced in 1888 is less than for 1887, being 6,253,295 barrels for 1888, valued at 72½ cents per barrel, making 4,533,639 dols. as the value of the year's product.

Phosphate Rock.

The production declined to 433,705 long tons, but the total value increased slightly to 1,951,673 dols. on account of better prices. The trade in manufactured fertilisers was very prosperous.

Salt.

The industry shows only slight changes. In 1888 the production was 8,055,881 barrels of 280 pounds, valued at 4,377,204 dols. In 1887 the product was 8,003,962 barrels, worth 4,093,846 dols. Kansas became a commercial source of salt in 1888, producing 155,000 barrels, with a prospect of still greater increase in 1889.

Bromine.

The product was 307,386 pounds, worth 95,290 dols., an increase from 199,087 pounds in 1887, worth 61,717 dols. The price remained at 31 cents per pound.

Borax.

The production was restricted to 7,589,000 pounds, worth 455,340 dols., at 6 cents per pound for the average quality. In 1887 the product was 11,000,000 pounds, worth 5 cents per pound.

Sulphur.

The sulphur refinery in Utah was partially burned. This and litigation over the property prevented any production in 1888. The supply came principally from Sicily, with small importations from Japan. It was practically all made into sulphuric acid.

Pyrites.

Production 54,331 long tons, valued at the mines at 167,658 dols., a slight increase in quantity over the previous year.

Barytes.

The production from Missouri, Virginia, and New York increased to 20,000 long tons, worth at the mines 110,000 dols. In 1887 the product was 15,000 long tons, worth 75,000 dols.

Gypsum.

The domestic supply comes principally from Ohio and Michigan, with smaller amounts from New York, Virginia, Kansas, Colorado, California, Dakota, and Utah. The product in 1888 was 96,000 short tons of crude gypsum, valued at 430,000 dols. A large portion of the supply is imported from Nova Scotia, where 126,118 tons, worth 121,579 dols., were produced in 1888.

Ozokerite.

From the region of Soldier's Summit, Utah, about 20,000 pounds of crude mineral wax were produced, worth 1,000 dols. in New York, where the material was sold. An increase is probable in 1889.

Soapstone.

Production about 15,000 tons, worth 50,000 dols. before shipment.

Asphaltum.

The product of 1888 includes 700 tons of gilsonite mined in Utah, 3,100 tons of ordinary asphaltum, principally from California, and 50,000 tons of bituminous rock quarried in California for pavements in competition with asphaltum; total value, 331,500 dols.

Feldspar.

The consumption for potters' use declined to 8,700 long tons, worth, in Trenton, New Jersey, 50,000 dols. In 1887 10,200 long tons were produced, worth 56,100 dols.

Flint.

For potters' use the consumption was 16,250 long tons. Including that for sand-paper and for glass, the consumption was about 30,000 tons, worth, unground, 175,000 dols.

Potters' Clay.

The consumption included 18,000 long tons of kaolin or china clay, 5,250 tons of ball clay, and 13,500 tons of fire-clay, worth altogether 300,000 dols.

Mica.

Owing principally to the use of smaller sizes in stoves, the production of sheet mica decreased from 70,500 pounds in 1887 to 48,000 in 1888, valued at 70,000 dols. There is increased demand for mica waste.

Mineral Paints.

The product, including ochre, metallic paints, and small amounts of umber and sienna, increased to 24,000 long tons, valued at 380,000 dols.

Graphite.

The production of pure graphite was limited to Ticonderoga, New York, and is reported as unchanged. The total production of pure material was 400,000 pounds, worth 33,000 dols. Small amounts of less pure material for foundry facings, &c. were produced in North Carolina, and at Cranston, Rhode Island.

Fluorspar.

The production, limited to the neighbourhood of Rose-clare, Illinois, and Evansville, Indiana, is reported at 6,000 tons, worth 30,000 dol., an increase of 1,000 tons over 1887.

Infusorial Earth.

The product came principally from Maryland, and amounted to 2,500 short tons, worth, before shipment, 12,500 dol.

Zircon.

During 1887 and 1888, 25 tons of zircon were mined, principally in Henderson county, North Carolina, and sold for 10,000 dol., for the manufacture of incandescent gas burners. About 4 tons of monazite, one ton of allanite, 600 pounds of samarskite, and 500 dol. worth of yttrium minerals were produced for the same use. About 6 tons of monazite and 5 tons of cerite were also imported.

Mineral Waters.

Amount sold in 1888, 9,628,568 gallons, valued at 1,709,302 dol. In 1887 the product was 8,259,609 gallons, worth 1,261,473 dol.

Totals.

The total value of the minerals produced in 1888 was 591,659,931 dol. It is recognised that this is the sum of the values of substances taken in various stages of manufacture, and hence not strictly comparable with each other; still it is the most valuable means for comparing the total products of different years. The result is an increase of nearly 50,000,000 dol. beyond the value of the product in 1887. In that year nearly every mineral industry showed an increase, and hence an increased total was evident. But the fact that the increase was so very large was due to rather exceptional conditions in a few important industries, and it could not reasonably be expected that a similar combination of circumstances would result in even a larger total value for 1888. Nevertheless, the unprecedented stimulus given to the production of copper by an artificial price increased the total value of that product nearly 13,000,000 dol., or nearly enough to offset the decline in the total value of pig iron. The other important factors in the increase were coal and the other fuels which followed the increased quantity of metals. With the anticipated decline of copper to the normal demand, a decline in the total value of the product in 1889 will not be inconsistent with the natural development of our mineral resources.

Metallic Products of the United States in 1888.

	Quantity.	Value.
		Dols.
Pig iron, spot value..... Long tons	6,489,738	107,000,000

* Articles of chemical interest only are given in this table, hence the items and totals do not agree.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

9903. H. T. Green. Means for evaporating saline and other saccharine solutions, and other liquids and semi-liquid substances. June 17.

9975. A. J. Boulton.—From P. Varin. Filters. June 17.

10,096. F. G. Harvey. See Class XVI.

10,251. T. Geutzen and A. Wegener. Filters. Complete Specification. June 24.

10,361. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes, France. An improved method or process of and apparatus for the lixiviation of various materials. June 25.

10,385. R. Fölsche. An improved centrifugal. June 26.

10,423. J. V. Davis. Improvements in hydrometers, and in apparatus in connexion therewith. Complete Specification. June 27.

10,521. G. H. Barrus. Improvements in apparatus for determining the quantity of moisture in, and measuring the heat of steam. Complete Specification. Date applied for under Patent Act, 1883, sec. 103, November 30, 1888, being date of application in the United States.

10,560. W. A. Cox. Improvements in calcining or roasting furnaces. June 29.

10,679. T. Whittaker. Perforated grinding mills for reducing to fine powder hard grindable substances. July 2.

10,686. H. J. Haddan.—From J. P. y Rodoreda and E. P. y Rodriguez, Spain. Machinery for triturating and crushing substances. July 2.

10,907. W. P. Thompson.—From N. Notkin, Russia, and P. Marix, France. New or improved method of distilling products by means of steam, and classifying or separating them according to their respective points of vaporisation, and apparatus therefor. July 6.

10,910. W. P. Thompson.—From W. Schleicher, Germany. Improvements in heating or annealing furnaces with retorts. July 6.

10,945. J. Vickers, T. Vickers, and J. Vickers, jun. Apparatus for feeding fuel to and in furnaces. July 8.

10,955. J. Johnston. Apparatus for heating, drying, and other purposes. Complete Specification. July 8.

11,104. J. Carr. Improvements connected with the manufacture of illuminating gas from coal. July 10.

11,121. S. A. Mackie. Improvements in the manufacture of artificial fuel. July 10.

11,125. F. Sanders. Improvements in retorts for producing gas. July 10.

11,164. F. T. Schmidt. Improvements in the method of and apparatus for consuming smoke. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

8852. J. E. Hall. Apparatus for consuming smoke and economising fuel. June 26.

9450. H. T. Hilliseher. Apparatus for mixing gases and regulating the pressure or flow thereof. July 10.

10,361. E. Bazin. Means and apparatus for producing cold. July 10.

11,268. E. Theisen. Condensing apparatus. July 17.

11,888. W. H. Northcott. Machinery for compressing air and gases. June 26.

12,112. T. Smith. See Class II.

12,188. T. Cain. See Class II.

12,318. J. Jardine and J. Ferguson. Gas and air reversing valves for regenerative, smelting, and other furnaces. July 17.

12,784. B. E. R. Newlands. See Class XVI.

13,885. R. Siekel. Promoting consumption of smoke and suppressing combustion in boiler tubes and other flues. June 26.

15,060. F. F. Clarke.—From F. F. Clarke. Apparatus for compressing air or other gas. June 26.

15,675. T. McDougall and J. Jardine. Apparatus for incinerating spent alkaline lyes or other waste products containing carbonaceous matter. July 17.

17,521. E. J. T. Digby. Means for manufacturing crucibles, &c. June 26.

1889.

681. The Native Guano Co., Lim., and C. E. Robinson. Apparatus for measuring liquids. July 3.

2528. W. Hucks. Method and apparatus for centrifugally separating solids and other matter from liquids. June 26.

7548. C. Salamon. Process for drying, desiccating, and roasting. July 3.

9200. A. Keddle. Improvements relating to thermometers. July 17.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

9916. A. M. Levy. Improvements in carburettors or apparatus for enriching or producing gas. June 17.

9956. C. Armitage. Improvements in means for revivifying the agents used in the purification of coal gas. June 17.

10,101. W. J. Pughley. Improvements in the manufacture of fuel. Complete Specification. June 20.

10,164. W. Crookes and F. I. Ricardo-Seaver. Improvements in the treatment of water-gas. June 21.

10,256. A. J. Boulton.—From W. G. Wood, Canada. Improvements in manufacturing gas. Complete Specification. June 24.

10,277. J. Dewar and B. Redwood. Improvements in the distillation of mineral oils and like products, and apparatus for that purpose. June 24.

10,327. J. Ward. Lighting gas by means of a spontaneously inflammable gas. June 25.

10,340. S. Clarke. Improvements in night lights. June 25.

10,392. H. J. Haddan.—F. F. Amoroso, Italy. Improvements relating to the burning of liquid fuel in boiler furnaces and the like. June 26.

10,488. J. H. R. Dinsmore. Improvements in or connected with apparatus used in the manufacture of gas from coal and analogous substances. June 28.

10,514. F. Hulwa. A manufacture of briquettes or block fuel. June 28.

10,581. J. C. Johnson. A new or improved producer for making ordinary producer-gas and water-gas and coke. June 29.

10,658. W. P. Thompson.—From A. Mason, United States. Improved method and apparatus for burning culm or pulverised coal. July 2.

10,659. W. P. Thompson. — From A. Mason, United States. Improved process for burning coal and hydrocarbon fuel, and apparatus therefor. July 2.

10,660. W. P. Thompson. — From J. Wilson and A. Mason, United States. Improvements in or appertaining to appliances for burning hydrocarbons.

10,661. W. P. Thompson. — From J. Wilson and A. Mason, United States. Improved process for burning petroleum and other hydrocarbons, and apparatus therefor. July 2.

10,697. G. Bower. Improvements in the production or manufacture of hydrogen gas. July 2.

10,700. J. W. Rock, C. G. Moore, J. H. Wood, and J. B. Nicholson. An improved gas-making apparatus. Complete Specification. July 2.

10,829. R. van Steenberg. Improvements relating to the manufacture of gas, and to apparatus therefor. July 4.

11,007. T. F. Fernandez. The prompt, absolute, and efficacious detection of any escape or leakage of the gas called or known as "water-gas," by incorporating, impregnating, blending or impregnating with, or communicating or imparting to, the said gas the odoriferous properties of musk. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9239. T. Nicholson. Gas and coke producers, and apparatus for collecting the bye-products. June 26.

10,224. The Gaseous and Liquid Fuel Supply Company, Limited, and Thwaite. The generation of gaseous fuel, and combustion thereof. June 26.

11,631. J. Frodsom and A. McLinden. Combustion of gas in blast furnaces, &c. July 10.

12,112. T. Smith. Apparatus for extracting coke from coke ovens, lime from lime kilns, &c. July 10.

12,188. T. Cain. Means for economising fuel, increasing the heating properties of the products of combustion, and preventing escape of black smoke. July 10.

12,281. J. Cunningham. Apparatus for charging gas retorts. July 10.

12,518. H. S. Maxin. Apparatus for naphtholising or carburetting illuminating and other gas. July 10.

12,608. L. Mond and C. Langer. Obtaining hydrogen. July 10.

13,074. W. Kusnezoff. Apparatus for the purification of gas. July 10.

1889.

6567. W. Deighton. Gas-producer apparatus and appliances for the manufacture of water-gas and other gases. July 17.

7531. H. J. Newcome. Condensing, purifying, and abating smoke from ordinary fires. July 3.

8179. A. Runge. Charging trough for gas retorts, and apparatus for raising and operating the same. July 17.

8192. J. von Langer and L. Cooper. Generating water-gas and producer-gas. June 26.

8519. V. B. D. Cooper. Manufacture of gas for heating and other purposes. July 17.

9061. B. van Steenberg. Manufacture of water-gas and apparatus therefor. July 10.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

10,999. R. F. Craig. Improvements in obtaining acetic acid or acetates from wood or other organic substances yielding it. July 9.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

10,630. B. Willecox. — From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture of anthraquinone sulpho-acids. July 1.

10,934. The Clayton Auline Co., Lim., and C. Dreyfus. The preparation of new sulphonic acids suitable for the manufacture of colouring matters. July 6.

11,000. H. H. Lake. — From Wirth and Co., agents for K. Ochler, Germany. Improvements in the production of colouring matters. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,563. J. V. Johnson. — From The Farbenfabriken vorm. F. Bayer and Co. Manufacture of diethylmercaptol and of a sulphone therefrom. July 3.

12,796. O. Huray. — From The Farbwerke vorm. Meister, Lucius, and Brünig. Production of green and bluish-green colouring matters. July 10.

1889.

3628. A. Bang. — From Dahl and Co. Production of dinitrodibenzylbenzidine and dinitrodibenzyltolidine and transformation of the same into diamidodibenzylbenzidine and diamidodibenzyltolidine respectively. July 10.

7588. A. Bang. — From Dahl and Co. The production of paranitrobenzylsulpho acid and also azo-colouring matters from the amidobenzylsulpho acid corresponding to this nitro compound. June 26.

9384. H. D. Kendall. Production of colouring matter from coal-tar products. July 10.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

9904. R. S. Burn. An improved method of treating cotton fibre or masses of cotton fibres preparatory to being worked up into yarn, for weaving or manufacturing purposes; applicable to fibres, animal or vegetable, other than cotton. June 17.

9946. R. Armitage. Improvements in the process of and apparatus for dyeing, dressing, and winding wett for weaving. June 17.

10,010. C. Puech. Process for separating the wool from pieces of rabbit skins and other skins of a similar kind. June 18.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

9919. H. H. Leigh.—From G. I. Lepaulard and E. P. Huard, France. An improved dyer's mordant. June 17.

9946. R. Armitage. *See* Class V.

10,360. E. Maertens. Improvements in the dyeing, scouring, or like treatment of yarn or other fibrous materials, and in apparatus therefor. June 25.

10,993. B. Willeox.—From The Farbenfabriken vorm F. Bayer and Co., Germany. Improvements in the manufacture of tannin compounds, more especially intended for printing purposes. July 8.

11,098. T. O. Arnfield. Improvements in and connected with apparatus for dyeing, washing, and otherwise similarly treating yarn in hanks. July 9.

COMPLETE SPECIFICATION ACCEPTED.

1888.

13,175. W. E. Heys.—From C. Vandermeirsche. Apparatus for dyeing and similarly treating textiles and fibres in all stages of preparation. July 17.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

10,142. A. S. Ramage. Method of preparing iron oxides from ferrous solutions. June 21.

10,205. A. Reyckler. A method of preparing binoxide of manganese. June 2.

10,554. T. Parker and A. E. Robinson. Improvements in and connected with the utilisation of sulphate of iron galvanising pickle. June 29.

10,909. S. Dyson and H. Dyson. Improvements in treating certain liquors or solutions containing chromic oxide or its salts, and in obtaining chromate of soda therefrom. July 6.

11,247. G. I. J. Wells.—From S. Pick, Galicia. Improvements in or appertaining to the treatment of the waste liquor from ammonia-soda works. July 13.

11,268. J. Meikle, jun. Improvements in and relating to the recovery and utilisation of carbonic acid. July 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,135. C. Netto.—From C. Winkle. Manufacture of artificial cryolite and similar compounds. June 26.

12,543. W. White. Manufacture of chloride of aluminium with other chlorides. July 3.

13,070. B. Willeox.—From The Badische Anilin und Soda Fabrik. Production and retention of chlorine in liquid state, suitable for transport or storage, and apparatus therefor. July 17.

1889.

8045. H. E. Newton.—From L. O'Brien. *See* Class X.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

9960. D. Lucas. Printing upon and decorating china, earthenware, glass, and other surfaces. Complete Specification. June 17.

9979. E. Leak and H. Aynsley. Improvements in the manufacture of grooved shields used in supporting pottery-ware while being fired. Complete Specification. June 17.

10,088. The Broseley Tiles Co., Lim., and J. Crump. Improvements in the manufacture of earthenware quarries or tiles. June 20.

10,322. W. Lutwyche. Improvements in the manufacture of translucent enamel, and in the application of the same in relief for the decoration of glass, metal, or any ceramic ware. Complete Specification. June 25.

10,887. D. Chapman. Improvements in casting or forming articles of pottery, including china and earthenware. July 5.

11,064. E. E. Cousins.—From B. E. Olsen, Canada. Improvements in fusible compounds suitable for the manufacture of drain pipes, flushing chambers, and the lining of conduits. July 9.

11,127. J. W. Barker. An improved method of enamelling and glazing the bowls of clay tobacco pipes. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,450. H. A. Paveley. Utilisation of waste and other glass. July 17.

12,596. W. J. Temple, F. W. Rogers, C. W. Trotman, and T. F. Hobbs. Enamelling or decorating slate, marble, &c. June 26.

18,577. W. H. Turner. Painting or printing upon earthenware. July 17.

1889.

8403. W. J. Bleuko. Process and apparatus for producing sheet glass with or without ripples or designs upon one surface. July 17.

9645. H. J. Allison.—From C. C. Gilman. Manufacture of porous earthenware. July 17.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

9927. H. H. Lake.—From C. T. Lee, United States. An improved compound suitable for the manufacture of various articles by moulding. Complete Specification. June 17.

10,122. D. Ker. A new kerb for street or road paving, and for other purposes. June 21.

10,282. A. E. L. Skazenger. Improvements in paving. June 24.

10,378. C. Coops. Improvements in paving. June 26.

10,824. J. Brunton and L. Griffiths. Improvements in apparatus for mixing the materials used in the manufacture of artificial stone, concrete, and the like. July 4.

10,914. H. W. de Lespare and W. H. Shafto. Improvements in the manufacture of concrete for ordinary, useful, ornamental, and artistic purposes. July 6.

10,997. J. B. King. Material for the treatment of walls and the like. Complete Specification. July 9.

11,128. G. Batchelor. Improvements in arrangements for drying slurry by the waste heat from cement kilns. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9761. J. S. Palmer. Plastic wall decoration composition. July 10.

10,586. A. McLean. Blocks or slabs for paving. June 26.

13,211. J. Rust. Vitreous material for paving, &c. July 17.

18,771. W. Millar, G. M. R. Layton, and T. Grover. Fireproof building construction. July 17.

1889.

961. C. J. Widwark. Manufacture of cement. July 17.

X.—METALLURGY, MINING, &c.

APPLICATIONS.

9905. H. A. Becker. Improvements in the conversion of crude iron into malleable iron and steel, and apparatus therefor. June 17.

9987. The Alkaline Reduction Syndicate, Lim., and A. B. Cunningham. Improvements in the treatment of zinc ores. June 18.

10,154. J. C. Bull. Improvements in the manufacture of copper alloys. June 21.

10,159. A. Piat. Improvements in furnaces for melting metals. June 21.

10,224. J. Powell. Improvements in or connected with ingot moulds. June 22.

10,274. H. Cave. An improved process and apparatus for the amalgamation of gold and silver contained in their ores. June 24.

10,279. R. E. Evenden. A new or improved apparatus for washing and separating gold and some other minerals and substances. Complete Specification. June 24.

10,288. H. H. Lake.—From O. B. Peck, United States. Improvements in apparatus for use in decomposing metallic salts and for desulphurising ores. Complete Specification. June 24.

10,298. J. H. Pollok. Improvements in the wet method of extracting gold. June 25.

10,394. J. Harper. Improvements in the treatment of gold and silver ores by the hydrometallurgical, or wet method. June 26.

10,422. A. W. Dennes.—From D. Dennes, United States. Improvements in barrels for treating auriferous, argentiferous, and other ores by means of chlorine, bromine, or any other suitable reagents. June 27.

10,437. T. Parker and A. E. Robinson. Improvements in the manufacture of phosphorus. June 27.

10,472. J. Y. Johnson.—From C. Pieper, Germany. Improvements in compound steel armour plates, and in the manufacture thereof. June 27.

10,496. F. W. Rose.—From T. K. Rose and D. Demer, United States. An improved apparatus for obtaining the solution of precious metals from their ores after they have been under treatment by some reagent. June 23.

10,639. H. Ritter von Dahmen and A. S. Collin. Process and apparatus for the production of metallic aluminium from oxide and silicate compounds, such as corundum, bauxite, kaolin, and the like. July 1.

10,835. T. Hydes. Improvements in the treatment of blast-furnace slag and other slags, and in the apparatus therefor. July 5.

10,836. T. Hydes. Improvements in the treatment of blast-furnace slag and other slags, and in the apparatus used therein. July 5.

10,991. P. H. Adams, jun., and O. T. X. Adams. Improvements in apparatus for use in decomposing metallic salts and desulphurising ores. Complete Specification. Date applied for under Patent Act, 1883, sec. 103, December 8, 1888, being date of application in the United States.

11,020. P. H. Adams, jun., and O. T. X. Adams. Improvements in apparatus for use in decomposing metallic salts and desulphurising ores. Complete Specification. Date applied for January 3, being date of application in the United States.

11,021. P. H. Adams, jun., and O. T. X. Adams. Improvement in plant for use in smelting ores. Complete Specification. Date applied for January 3, being date of application in the United States.

11,055. H. S. Holt.—From J. Clegg, United States. Improvements in alloys. July 9.

11,083. P. H. Adams, jun., and O. T. X. Adams. Improvement in plant for use in smelting ores. Complete Specification. Date applied for January 3, being date of application in the United States.

11,202. R. Welford. Improvements in the method and apparatus for treating ores. July 12.

11,237. J. H. Pollok. Improvements in the extraction of gold from ores. July 12.

11,266. W. H. Luther. Improvements in and relating to baths for and pickling of metallic plates and other articles for galvanising purposes. July 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9570. T. W. Helliwell. Process of treating steel or iron, or a combination thereof, so as to prevent oxidation. June 26.

9848. J. Sumnerhill. Carburising and coating iron or steel, in the form of sheets, wrought or cast plates, or manufactured articles. June 26.

10,223. J. S. MacArthur, R. W. Forrest, and W. Forrest. Extracting gold and silver from ores, &c. July 17.

10,262. M. Gledhill. Forging metal cylinders, armour plates, &c., and apparatus therefor. June 26.

10,785. W. G. Foster. Manufacture of sodium and potassium, and apparatus therefor. July 3.

11,512. P. M. Parsons. Metallic alloys. July 3.

12,074. Le Comte E. de Rotterdam. Extracting gold, silver, and other metals from refractory ores, sands, and residues. June 26.

12,293. G. Allan and T. Turner. Manufacture of cast anchors, and moulds for casting anchors and shanks of cast steel or alloy. July 10.

12,337. R. C. Thompson. Recovery of tin, spelter, solder, &c., from scrap tin plate and other coated metal wares. July 10.

13,125. W. White. Manufacture of sodium and potassium. July 10.

13,182. C. A. Burghardt. Reduction of zinc oxides. July 17.

13,358. Sir H. H. Vivian. Manufacture of plates, &c., from alloys of copper and nickel by rolling at a red heat. July 17.

13,359. H. Doetsch. Extraction of copper from copper ores. July 17.

14,916. I. Beardmore. Distributing or regulating valve of regenerative gas furnace for steel melting, &c. June 26.

1889.

8045. H. E. Newton.—From L. O'Brien. Process for making metallic sulphates in solution. July 3.

8856. H. H. Lake.—From C. M. Ball, S. Norton, and A. T. Porter. Separation of magnetic ores from phosphorus and other impurities, and apparatus therefor. July 17.

9187. H. H. Chandler. Flux for coating iron or steel with copper and for welding copper. July 10.

9176. A. A. Lockwood and H. Chappel. Treatment of auriferous and argentiferous materials, and apparatus therefor. July 17.

XL.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

5994. E. Maigrot and J. Sabates. See Class XVI.

10,061. G. J. Atkins. Improvements in apparatus for separating gold and other metals from their ores by the aid of electricity. June 18.

10,209. J. Zacharias and F. Marx. Improvements in electrical accumulators or storage batteries. June 22.

10,517. E. Frankland, N. Story-Maskelyne, A. H. Hough, and D. G. FitzGerald. Improvements in elements for voltaic batteries. June 28.

10,695. H. H. Lake.—From C. A. Hussey and E. H. Brown. Improvements in electric batteries. July 2.

10,696. H. H. Lake.—From C. A. Hussey and E. H. Brown. Improvements in electric batteries. July 2.

10,775. A. Weleker. An improved exciting liquid for electric batteries. July 3.

10,822. G. Button and W. E. Wyeth. Improved apparatus for extracting gold and silver from their ores by electrical amalgamation. July 6.

10,889. E. M. H. Andreoli. Improvements in the electrolytic production of hydrochlorite of sodium. Complete Specification. July 5.

11,011. W. P. Thompson.—From P. H. Alexander, United States. Improvements in storage batteries. July 9.

11,049. J. J. Wood. Improvements in dynamo-electric machines, in part applicable to electro-motors. July 9.

11,070. J. Y. Johnson.—From A. L. Riker, United States. Manufacture of elements or plates for secondary batteries. July 9.

11,242. Siemens Brothers and Co., Limited.—From Siemens and Halske, Germany. Improvements in dynamo-electric, magneto-electric, and electro-dynamic machines. July 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

11,479. T. Parker and A. E. Robinson. Manufacture of iodine by electrolysis. July 10.

12,907. T. Parker and W. Lowrie. Dynamo-electric machines. July 10.

13,000A. T. M. Sargent and O. R. Sivete. Electric batteries. July 17.

13,215. W. Clarke.—From L. Maiche. Electric batteries. July 3.

18,751. G. C. Dymond.—From C. Gassner. Galvanic batteries. July 3.

1889.

1557. C. H. Mehner. Dry galvanic cells. July 3.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

10,419. A. Harrison and W. T. Thorp. An improvement in making soap for washing purposes. June 27.

10,587. J. Roots. An improved lubricating compound July 1.

11,079. E. Edwards.—From M. A. Krause and J. Lewandowski, Germany. Improvements in compounds for reducing the heat caused by the friction of journals and the like, and in the method of preparing and using the said compound. July 9.

11,272. R. Hunt. Improvements in treating crude cottonseed oil, and oils containing resinous matter and free fatty acids to obtain oil, resinous colouring matter, and soap. July 13.

11,292. H. Earich. A new or improved process for producing hard potash and similar soap from solid or liquid fats. July 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9857. J. J. Bowley. Manufacture of soap and detergents. July 3.

12,001. J. Crossley. Composition of soap for cleansing and disinfecting purposes. June 26.

1889.

5680. G. R. B. Kempton. Blue soap for laundry washing. June 26.

8196. R. O. Englaub. Apparatus for rectifying glycerin. June 26.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

10,086. W. Walker.—From W. E. Sendey, France. An improved process for the manufacture of sulphate of lead, and apparatus therefor. June 20.

10,124. C. A. Burghardt. Improvements in the preparation or treatment of paints, pigments, dry colours, bronze, or metallic powders, and leaves and other similar substances. June 21.

10,368. W. Cromack. Improvements in the manufacture or composition of paints. June 26.

10,428. L. M. Lamb and D. Boyd. Improvements in lacquers and varnishes. June 27.

10,858. E. S. Baldwin.—From J. Smith, New Zealand. A new composition for waterproofing textile fabrics, and as a paint for wood and other surfaces. Complete Specification. July 5.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

10,110. J. Hauff. Means for freeing skins, kips, and hides from lime, and for causing the same to swell. Complete Specification. June 20.

10,223. W. D. Goode. Improved apparatus and process for curing or tanning skins, kips, and hides. June 22.

10,326, G. A. H. Gabet. Process for separating the constituent elements of bones, that is phosphoric acid, lime, ossein, and fat. June 25.

10,900, W. G. Richardson. An improved manufacture of liquid waterproof glue. July 6.

10,968, B. Nicholson and T. Palmer. The treatment of tanning and other vegetable extracts for decolourising the same. July 8.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

9994, E. Maigrot and J. Salates. Improvements in apparatus for the manufacture of sugar by electricity. Complete Specification. June 18.

10,096, F. G. Harvey. Improvements relating to the evaporation or concentration of sugar and other liquids, and to apparatus therefor. June 20.

11,136, S. Pitt.—From L. W. Tracey, United States. Improvements in evaporators or apparatus for the treatment of cane juice. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,784, B. E. R. Newlands. Means or apparatus for drying slabs of sugar, applicable for heating and cooling other articles and for analogous purposes. July 17.

1889.

8622, C. Steffen. Apparatus for producing white sugar. July 17.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

10,620, J. H. Carpenter. A vacuum yeast separator, skimmer, and press. July 1.

10,667, W. W. Mutter and W. Dawson. Improvements in or relating to distillers' safes, said improvements being also applicable for check-sampling the spent wash at outlets of "patent" stills. July 2.

10,740, E. Larsen. An improved method of facilitating the drying of distillers' spent wash and similar matter. July 3.

10,762, T. Vogel. Improvements in apparatus for treating yeast. July 3.

10,891, J. Sleeman. Improvements in the method of malting grain, and in machinery or apparatus therefor. July 5.

10,988, J. Sleeman. Improvements in the method of malting and drying grain, and in machinery or apparatus therefor. July 8.

11,180, J. Sleeman. Improvements in the method of malting and drying grain, and in machinery or apparatus therefor. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,642, A. T. Christophe. Rectification of alcohol. July 3.

13,212, L. Groezinger. Producing extract of hops and preparing beverages therefrom. June 26.

15,261, W. Kuhn. Apparatus for Pasteurisation of beer, wine, &c. June 26.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

10,208, A. N. Ford. Improvements in treating eggs. 22 June.

10,352, G. A. Brinck and A. W. Rhenström. Improvements in food preparations. 25 June.

10,789, F. McIntyre. An improved process for the preservation of foods. 4 July.

B.—Sanitary Chemistry.

10,843, M. Lunn. Improvements in the treatment of sewage and of the residual precipitate. 5 July.

C.—Disinfectants.

10,575, E. Serrant. The preparation of sozolic acid. 29 June.

COMPLETE SPECIFICATION ACCEPTED.

1888.

B.—Sanitary Chemistry.

11,841, A. N. Bertram. Destroying the noxious fumes arising from chemical manufactures. 17 July.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

9,927, H. H. Lake.—From C. T. Lee. See Class IX.

10,427, J. Neville. Improvements in blotting-paper. 27 June.

10,914, J. R. Thame and H. Sanguinetti. Improvements in the manufacture of hollow ware from paper or like pulp, and in apparatus employed therein. 6 July.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,502, W. Hall. Apparatus for straining paper pulp, &c. 10 July.

1889.

8946, J. Husnik. Production of semi-transparent designs on or in paper by means of gelatin relief printing. 10 July.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES,
AND EXTRACTS.

APPLICATIONS.

10,280. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes, France. An improved process of recovering volatile solvents retained in substances treated therewith. June 24.

11,099. T. Parker and A. E. Robinson. Improvements in the manufacture of carbon bisulphide. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

11,479. T. Parker and A. E. Robinson. *See* Class XI.

13,169. C. W. E. Kolbe. Manufacture of salols. July 17.

XXI.—PHOTOGRAPHIC PROCESSES AND
MATERIALS.

APPLICATIONS.

9921. H. Devevil and W. Gallagher. Improvements in photographic negatives and sensitised plates for use in photo-illustrative processes. Complete Specification. June 17.

10,393. J. S. Fairfax.—From F. Crane, United States. Improvements in or relating to films or supports for photographic negatives or prints. June 26.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

10,312. C. O. Lundholm. Improvements in the manufacture of dynamite. June 25.

10,376. C. O. Lundholm and J. Sayers. Improvements in the manufacture of explosives. June 26.

11,084. C. E. Kelway. Improvements in explosive shell and torpedo fuses. July 10.

11,090. F. H. Snyder. Improvements relating to the manufacture of waterproof pellets and other pieces or charges of explosive material. July 10.

11,102. W. H. A. Kitchen and J. G. A. Kitchen. A new explosive to be called "Cycene," intended to be used as a substitute for gunpowder or other explosives used for blasting or other like purposes, or for shells used in connexion with ordnance. Complete Specification. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9799. J. A. Wanklyn. Smokeless explosives. July 17.

10,722. A. V. Newton.—From A. Nobel. Explosive compounds. June 26.

12,697. G. Trench. Pyrotechnic signals for use at sea. July 10.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 8.—Vol. VIII.]

AUGUST 31, 1889.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2 6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

COUNCIL FOR YEAR ENDING JULY, 1890.

President: Sir Lowthian Bell, Bart., F.R.S.

Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Müller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Harter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

Editor:

Watson Smith, The Owens College, Manchester.

ASSISTED BY THE FOLLOWING STAFF OF

Abstractors:

T. L. Bailey, Ph.D.	Chas. A. Kohn, Ph.D.
G. H. Beckett.	F. W. T. Krohn.
D. Bendix.	T. A. Lawson, Ph.D.
E. Bentz.	J. Walter Leather, Ph.D.
E. E. Berry.	A. Liebmann, Ph.D.
E. J. Bevan.	D. A. Louis.
Bertram Blount.	W. Macnab.
Arthur G. Bloxam.	J. M. H. Munro, D.Sc.
C. H. Bothamley.	H. S. Pattinson, Ph.D.
E. G. Clayton.	H. T. Penternmann.
Julius B. Cohen, Ph.D.	S. G. Rawson, D.Sc.
C. F. Cross.	A. Ree, Ph.D.
A. R. Davis.	F. W. Renant.
W. W. Haldane Gee, B.Sc.	Edward Simpson.
C. Napier Hake.	A. J. Smith, B.Sc.
Oswald Hamilton.	Oscar J. Steinhart, Ph.D.
John Heron.	A. L. Stern, B.Sc.
Bertram Hunt.	A. Studer, Ph.D.
C. C. Hutchinson.	Bertram Thomas.
D. E. Jones, B.Sc.	Eustace Thomas.
W. E. Kay.	V. H. Veley, M.A.
A. J. King, B.Sc.	R. Lloyd Whiteley.
F. S. Kipping, D.Sc.	A. Wingham.

NOTICES.

On and after the 30th of September the Editor's address will be "University College, Gower Street, London, W.C.," instead of Owens College, Manchester, as heretofore.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. Eyre and Sportswood, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

CHANGES OF ADDRESS.

Archbold, Dr. Geo., 1/o Phenix; 250, West 14th Street, New York City, U.S.A.

Bishop, Fred., 1/o Edinburgh; c/o Linlithgow Oil Co., Ltd., Linlithgow, N.B.

Communication.

ON THE PRECIPITATION OF COPPER AS SULPHOCYANIDE IN ASSAYING.

BY FRANK JOHNSON, F.G.S., E.L.C.

(Chief Chemist to the Tharsis Mines, Spain.)

IN the assay of copper ores and cupreous liquors it is almost invariably necessary to separate the copper from iron, zinc, or other metals as a preliminary to its estimation by any of the well-known methods.

This separation is usually performed by the use of sulphuretted hydrogen, hyposulphite of soda (sodium thio-sulphate), and occasionally of metallic zinc or iron.

During the last few years I have tried many experiments with the object of attaining a means of separation involving, for the assay, the least possible time, care, and manipulation. The result of my labours is the following method, which I have employed with success for many thousands of assays during the last four years, and which I find perfectly suited to the copper assay of Spanish pyrites and the copper liquors produced therefrom.

The ore is dissolved in any suitable acid, the excess of which should be mainly boiled off. The semi-fluid residue is diluted with about 20 times its volume of cold water and sulphocyanide of ammonium added to the extent of at least three times the weight of the copper possibly present. This will produce with the ferric salts a deep red colouration, then stannous chloride solution is added until bleaching ensues, and a liquid more or less turbid with precipitated cuprous sulphocyanide and the insoluble portion of the ore results.

I find 5 grms. a very convenient quantity to take of ordinary cupreous pyrites of $\frac{1}{2}$ to 5 per cent. copper, and I add to the solution 5 cc. of ammonium sulphocyanide solution of 100 grms. per litre commercial crystallised salt. This quantity is safely sufficient for the precipitation of $\frac{1}{2}$ 3 gm. copper, and is not enough when diluted by the assay to about 200 cc. to have any solvent effect on the cuprous sulphocyanide precipitated. If the colour of the ore or its solution indicates the presence of more than the above-named amount of copper, proportionately more sulphocyanide solution must be added.

Stannous chloride solution is made by dissolving commercial protochloride in hydrochloric acid to saturation, and is kept in a bottle containing rods of metallic tin. This solution is added to the assay immediately after the sulphocyanide. Being very strong, about 10 cc. are usually sufficient to discharge the colour due to ferric sulphocyanide.

A good close filter-paper is now required—perfectly free also from all traces of colour. Munktell's are the best of those I have yet tried, though other Swedish papers approach it closely.

The assay is filtered through a paper of 5 or 6 inch diameter which is washed with water containing about one per cent. of commercial hydrochloric acid—either partially, by one rinse round, or thoroughly, according to the intended subsequent treatment.

Before proceeding to describe the most convenient ways of estimating the copper, I may say that though it is safest to leave as little excess of acid as possible when evaporating the dissolved ore, enough must be left to allow of the complete solution of the saline products when water is added. In the diluted solution as much as five per cent. of free acids may be present, either sulphuric, hydrochloric, or nitric, though if much of the latter exists in the liquid care must be taken that its temperature be below 100° F. when the sulphocyanide is added or a mutually destructive reaction would occur. Below 100° F. nitric acid may be present without further inconvenience than the production of a dark colour in the liquid after reduction with tin, due, I believe, to some compound of iron with nitric peroxide.

Returning to the assay—on the filter is caught the cuprous sulphocyanide, the gangue of the ore, and traces of stannic hydrate; my usual routine is now to give one wash with acidulated water (one per cent. muriatic acid), allow that to run through, raise the filter-paper carefully by its edge, double and fold together, and drop the paper with its contents back into the dissolving flask, neglecting the traces of filtrate still clinging to the paper.

A dilute acid mixture is made of 1 part nitric acid, 1 hydrochloric, and 1 water; 50 cc. of this are poured on the wet filter and the flask is placed on a hot plate to boil gently for about a quarter of an hour, when all red fumes should have disappeared and the paper have become quite reduced to pulp. About a quarter of the bulk may be evaporated, but not more, as it is essential to avoid the action of strong acids on the paper.

Ammonia is now added to the assay, and when fairly cool it is titrated with solution of cyanide of potassium, standardised preferably with copper dissolved, precipitated as sulphocyanide, and dissolved as above, for the best paper often produces a faint yellowish colour in the finished assay, more especially if the ammoniacal solution is left in contact with the paper pulp for a long time before being titrated. This colour is of no consequence if present also in the standardisation.

The above (with, of course, the usual precautions of cyanide assaying, viz. quantity of copper, acids, ammonia, &c., and temperature same in standardisation as in assays) is what I have found to be the quickest method of assaying poor ores and liquors containing zinc accurately to within about one per cent. on the copper present.

The solubility of cuprous sulphocyanide in the acid supernatant liquid is only 2 or 3 parts per million, and may be quite disregarded if standardisation of the cyanide solution be performed with an approximately equal quantity of copper similarly dissolved and separated.

In filtering a precipitated assay it is important to notice if the filtrate is perfectly clear. Frequently the first few drops passing are turbid, in which case this portion must be returned to the filter. Occasionally when washing the filter the dilution of the filtrate causes a separation of stannic hydrate, which, however, is easily distinguished from the turbidity due to cuprous sulphocyanide.

Cuprous sulphocyanide is soluble in hot dilute nitric acid, being converted into a cupric solution which even after long boiling contains cyanogen in a form which interferes with the cyanide titration, causing a much less amount of cyanide to be required than would ordinarily be the case. If, however, both nitric and hydrochloric acids be used, diluted in the above-mentioned proportion with water, and the assay be boiled until all red fumes have disappeared, the resulting liquid can be safely assayed by the cyanide process.

The solution produced by dilute nitric acid alone cannot be assayed by electrolysis for the same reason unless it be first evaporated to dryness and strongly heated. The electrolytic assay can be applied to the solution in mixed acids by filtering from the paper pulp and evaporating with 1 or 2 cc. of sulphuric acid, taking up the residue with water and electrolysing.

I have performed the electrolytic assay many times prepared by the former and also by the latter of these means, and I find the latter very much more convenient. The paper pulp is reserved after washing and mixed with the liquid exhausted by electrolysis, ammonia being then added, the traces of copper left in the liquid and those in the paper pulp are estimated together colorimetrically.

The electrolytic assay with preliminary sulphocyanide separation has a good feature in that no arsenic, antimony, or bismuth are deposited with the metallic copper, nor have I ever noticed any blackening or other discolouration of the deposited copper even when left under the influence of the current for double the usual time, *i.e.*, two days.

Cuprous sulphocyanide is readily soluble in a solution of ferric sulphate, cupric salt, ferrous salt, and ferric sulphocyanide resulting. If this solution be acidified with sulphuric acid and a solution of potassium permanganate run in from a burette the red colour becomes lighter, changes to a brown, then to the blue due to cupric sulphate, and lastly a pink tint is produced by one drop of permanganate in excess. I find this reaction gives a very accurate and speedy means of assay. To apply it the following means are used:—

The paper, containing cuprous sulphocyanide and insoluble portions of the ore, is well washed, first once or twice with the dilute hydrochloric acid above mentioned, and then with hot water. The filter is raised, dropped back into the dissolving flask as before, and 50 cc. of acid ferric sulphate solution poured upon it. This solution contains about 100 grms. of ferric sulphate and 50 cc. H_2SO_4 per litre. The assay is slightly agitated to promote mixing of the contents of the paper with the solution. Permanganate solution is now run in until, after fresh agitation, the solution remains brown or olive-green. It smells strongly now of hydrocyanic acid and is taken to a sink chamber, heated, and allowed to simmer for 5 or 10 minutes, when probably the red-brown colour will have partly returned. 200 or 300 cc. of cold water are now added and the permanganate titration completed. A good strength for the permanganate solution is 20 grms. per litre. If the first pink colouration be taken as the finishing point, though it is soon discharged, the accuracy of the assay is not affected by the reducing power of the paper pulp. This may easily be verified by treating a clear paper with 50 cc. ferric solution, diluting with cold water as before, and adding permanganate. I have always found one drop suffice to produce a transient pink colour. The chief inconvenience about this assay is the evolution of hydrocyanic acid during titration. Where one or two assays only are to be performed there is no trouble, as only traces escape from each flask before it is heated. The check assays, of which I have performed some dozens by this process, usually agreed with the electrolytic assay or with the weighed amount of copper introduced to within $\frac{1}{2}$ per cent.

I have not as yet tried any experiments upon the application of this means of separation as a preliminary to the iodide assay, but I suppose that the liquid prepared as already described for permanganate titration, by careful washing and solution in dilute acid mixture, would, if nearly neutralised and sodic acetate added, yield a suitable medium for the iodide and hyposulphite assay.

No mention has here been made of reducing agents other than stannous chloride, as I have found no other approaching it in convenience. Sulphurous acid can be used if very little ferric iron be present, but otherwise it is very slow in its action. Hyposulphite of soda is for various reasons unsuitable.

In preparing the stannous chloride solution time must be allowed for the metallic tin immersed to precipitate any traces of copper present in the commercial salt. If the clear solution be then siphoned off it is easy to leave behind the black flocks adhering to the rods of tin.

In conclusion I have only to express my hope to have some criticism from those who may give a practical trial to the procedure here recommended.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements Connected with or Applicable to Baths or Vessels containing Liquids used in Electro-plating or Dyeing, or the Electrolyte of Storage Batteries and the like. E. Hopkinson and D. Appleton, Manchester. Eng. Pat. 8966, June 19, 1888. 8d.

By means of a circulating pump the surface liquid is drawn off and forced out through the perforations of a delivery pipe arranged near the bottom of the tank, thus maintaining an uniform density.—B. T.

Improvements in Weighing Scales or Balances. C. H. Bartlett, Bristol. Eng. Pat. 11,555, August 10, 1888. 8d.

ONE improvement is intended to prevent injury from jarring to the agate-stones used as bearing surfaces for the knife-edge centres, by the use of a spring or spring cushion made of metal or india-rubber. The two drawings attached to the specification show how this improvement may be applied either to a balance of the "Roberval type" or to hanging scales. A second improvement relates to a method of obtaining a very fine adjustment in a "Roberval" balance by means of a moveable weight.—E. S.

Improvements in Apparatus for Purifying Water in or for Use in Steam Boilers. J. Pollock, Belfast. Eng. Pat. 18,556, December 19, 1888. 8d.

A PERFORATED chest or chamber having within it a bar or bars of copper is introduced into the steam-boiler, and balls of zinc are allowed to roll upon the copper bar or bars, the copper and zinc being both kept clean by the motion of the balls. The chemical or galvanic action going on inside the chest prevents corrosion of or deposit of scales upon the boiler-plates.—B. T.

An Improved Drying, Desiccating, and Roasting Apparatus. C. Solomon, Brunswick, Germany. Eng. Pat. 7149, April 29, 1889. 6d.

A ROTATING drum, tapering towards both ends, is fed at one end through its hollow shaft with the materials to be treated, the gaseous and other matter for effecting the drying and other processes entering by the hollow shaft at the opposite end. The drum is made in two halves, connected together, each half being provided internally with helical or screw-like surfaces arranged in opposite directions, by which means the material is intimately mixed, and held in suspension whilst the gaseous products of combustion are driven through the apparatus to act upon it. The temperature may be observed by a "pyrometer," and the progress made ascertained by withdrawing a sample through an opening usually closed by a suitable cover. When the operation is completed a slide is drawn outward and allows the contents of the drum to fall into a receptacle. A drawing accompanies the specification.—E. S.

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	3d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	13d.
" 2s. 4d., " " 3s. 4d.	2d.

II.—FUEL, GAS, AND LIGHT.

Water-Gas. J. F. Bell. A Paper read at the Spring Meeting of the Midland Association of Gas Managers, held at Matlock Bath, May 16, 1889.

This paper embodies the results of the author's investigations into the comparative values of water-gas and ordinary coal-gas. After remarking that the patents so profusely taken out at the present day are almost identical with those of years ago, he goes on to point out that in America, where they have an abundance of anthracite coal well adapted for making water-gas, and plenty of cheap oil for carburetting it, the average price is 10s. 6d. per 1,000 cubic feet against 9s. 6d. per 1,000 cubic feet of coal-gas, and that the number of companies making water-gas is gradually decreasing. An average sample of water-gas contains by volume: hydrogen, 48 per cent.; carbonic oxide, 41 per cent.; carbonic acid, 6 per cent.; and nitrogen, 5 per cent.; or a total of 89 per cent. combustible gases, against 96½ per cent. in ordinary 17-candle coal-gas. Water-gas has a thermal value of only 291 B.T.U. per cubic foot (B.T.U. = lb. of water heated 1° F.) against 673 for coal-gas, so that to produce the same calorific effect, where both are available, less than half the latter will do as much as the former. Theoretically, if the whole calorific value of a ton of coke could be obtained as water-gas, 76,000 cubic feet should be produced, but in practice only about 23,000 cubic feet are obtained, the difference being chiefly represented by the sensible heat of the gases evolved, and the heat consumed in making producer gas during the intervals while the fuel is not hot enough to decompose steam advantageously. This producer gas, which the author distinguishes by the name of "producer water-gas," contains about 20 per cent. of carbonic oxide, and may be utilised to evaporate water, &c., &c. Its thermal value is only 73 B.T.U. per cubic foot, so it will be seen that if any practical value is to be obtained from it, it

must be used before its sensible heat has been lost by cooling. There is one respect in which water-gas has a decided advantage over coal-gas as a heating agent: its temperature of combustion is 4,320° F. against 3,970° F., a very valuable feature where intense local heat is required. It has been proposed that gas companies should supply a cheap fuel gas consisting of a mixture of coal-gas, water-gas, and producer water-gas, but the author does not think the scheme will answer. A ton of coal, first gasified in the usual way, and then used for the production of water-gas, would yield:—

	Cubic ft. B.T.U.	
Coal-gas.....	10,000 × 673 =	6,730,000
Water-gas.....	12,000 × 291 =	3,492,000
Producer water-gas..	42,000 × 73 =	3,066,000
Total.....	64,000	298
		13,288,000

Although this mixture is much superior to ordinary producer gas, the very fact of having to cool so large a volume for distribution means too great a loss in sensible heat for the process to work economically. Moreover, the cost of distributing so bulky a gas would be very heavy, and it is doubtful if the demand would justify the outlay that would be required. In the States the chief illuminating agent employed to carburet water-gas is naphtha, of which from 5 to 5½ gallons are required per 1,000 cubic feet. This alone would cost in England about 15d. per 1,000 cubic feet of gas produced. The author has but a poor opinion of the Falmehjelm incandescent system (this Journal, 1886, 424; 1888, 23 and 112; 1889, 533 and 534). He considers the magnesia combs too frail, and, apart from this, does not think the general public will ever adopt an arrangement which necessitates so much attention and such frequent renewals. With respect to the comparative costs of production, some interesting figures are given. Taking the capital laid out in plant for making and distributing 100,000,000 cubic feet of either kind of gas per annum as equal to 3*l.* 10s. per ton of coal, the costs work out somewhat as follows:

	Cost of Coal-Gas per 1,000 Cubic Feet.		Cost of Water-Gas per 1,000 Cubic Feet.
Manufacture (including gas making, purifying, repair, and maintenance of works, &c.)	d. 6·0	One-half this amount	d. 3·0
Distribution (including repair and maintenance of mains, services, &c.)	2·0	2·0
Rates and taxes.....	2·0	2·0
Management	0·8	0·8
Total working expenses.....	10·8	7·8
Coals—10,000 cubic feet of gas—at 10s. per ton less 65 per cent., being net amount received for residuals, leaving net cost of coal 3s. 6d. per ton	4·2	Coke—23,000 cubic feet of gas—at 10s. per ton with no residual products.....	5·2
Total coals and working expenses..	15·0	13·0
Interest on capital, 35,000 <i>l.</i> at 5 per cent.....	4·2	Two-thirds of this amount	2·8
Depreciation and renewal.....	1·8	1·2
		Add cost of naphtha for carburetting the water-gas (allowing for extra quantity of gas made by the naphtha).....	17·0
			13·0
Total cost per 1,000 cubic feet	21·0		30·0

From this it will be seen that carburetted water-gas costs 2s. 6d. per 1,000 cubic feet, against 1s. 9d. for coal-gas. The cost of the uncarburetted gas is only 1s. 5d. per 1,000 cubic feet, it is true, but against this is its low thermal value. The author concludes by saying that he "can conceive of no

commercial undertaking that has less chance of success, as now proposed, than the manufacture and distribution of water-gas in competition with coal-gas in England." Appended are some valuable tables showing the figures upon which the above results are based.

TABLE A.—CONSTITUENTS BY VOLUME AND WEIGHT OF ORDINARY 17-CANDLE POWER COAL-GAS; ALSO ITS CALORIFIC VALUE, &c.

Constituents of Coal-Gas.	Vol. Per Cent.	Weight of Gases at 60° F. and 30 in. Bar.	Weight of Constituents of Coal-Gas.	Heat of Combustion of Gases per Lb.	Calorific Value of Coal-Gas.	Oxygen required for Combustion.	Products of Combustion.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, &c.

Decomposition of the Neutral Fats by Heating under Pressure. C. Engler and S. Seidner. Dingl. Polyt. J. **27**, 515—526 and 572—576.

This is a continuation of the researches of the first named bearing on the problem of the formation of petroleum (Ber. **21**, 1816). An operation on the large scale was conducted in a patented apparatus of Krey's for distillation under pressure. The oil treated was that obtained from the Menhaden fish (*Clupea Tyronum*) of specific gravity 0.930, and consisting chiefly of tri-olein. The course of the distillation was as follows: the first evolution of gas was noticed at the expiration of five hours, shortly after this distillation commenced, the temperature being 325°, the pressure 10 atmospheres. The specific gravity of the distillate varied from 0.875 to 0.855. As the temperature gradually rose to from 400° to 425° the pressure sank to 4 atmospheres, the distillate running at the gravity 0.830—0.813.

The aggregate results of the first distillation were as follows:—Distillate, 339 kilos.; carbonaceous residue, 65 kilos. The difference of the sum of these from 492 kilos., the original weight of oil, *i.e.*, 88 kilos., represents the gases evolved and unavoidable loss. Of the 339 kilos. of distillate, 217 kilos. richer in undecomposed tri-olein, and of higher specific gravity, were redistilled with the following results:—

	Kilos.
Distillate	197
Residue	12
Gases and loss	8
	<u>217</u>

In the end the total weight of oily distillate amounted to 299 kilos.; of aqueous distillate 20 kilos. were collected. The distilled oil is of brownish colour with a marked green fluorescence, and does not appear to contain acrolein. A measured volume of the oil treated with various reagents in succession, showed the following diminutions, corresponding with the removal by combination of groups of constituents:—

	Vol. per Cent.
Water	0.4
Potash (alcoholic).....	4.8
Sulphuric acid	20.8
Mixture of the above with fuming acid	9.6

Fractional distillation of the distilled oil gave the following results:—

	Fraction.		
	Below 150°.	150°—300°.	Above 300°.
Volume, per cent.....	20.5	57.5	15.0
Weight "	25.9	58.0	16.1
Specific gravity	0.712	0.817	..

The mean percentage of saponifiable constituents in the original distillate may be taken at 5.7.

Experiments on the small scale, admitting of accurate measurements, were carried out in sealed glass tubes bent at an angle, the limb containing the oil being heated in an air-bath, the other projecting into the air, and being kept cool thereby. A comparison was instituted under these conditions, between the fish oil described above and synthetical tri-olein. Particulars below:—

(a.) *Fish Oil*.—Quantity taken 40 grms.

	Grms.	Per Cent.	Specific Gravity.
Gaseous products..	3.56	8.9	..
i. Distillate*	25.20	63.0	(0.837)
ii. Distillate†	6.60	16.5	(0.876)
Residue	4.64	12.6	..

* Of which 6.6 per cent. saponifiable.

† By heating residue from i. over naked flame.

(b.) *Tri-olein*.—Quantity taken 35.5 grms.

	Grms.	Per Cent.	Specific Gravity.
Gaseous products..	3.55	10.0	..
i. Distillate*	24.80	69.8	(0.815)
ii. Distillate.....	5.00	14.1	(0.853)
Residue.....	2.15	6.1	..

* Of which 5.4 per cent. saponifiable.

Under the condition of heating in a sealed tube the process of distillation takes place within the limits of temperature 365°—425°, the pressure, estimated from the volume of the gaseous products, amounting to from 20 to 25 atmospheres. The quantity of water formed is estimated at 1—3 per cent.

Constituents of the Distillate.—(a.) *From fish oil*.—In addition to the pentane, hexane, and heptane previously isolated (Dingl. Polyt. J. **269**, 138) the authors have separated: secondary hexane or di-isopropyl; secondary heptane or ethylisamyl; octene, secondary octane or di-isobutyl, and nonane. The percentage of olefines estimated from the results of treatment of the oil with sulphuric acid, amounts to 37 (by vol.). Acetylenes are probably also present. The evidence as to the presence of aromatic hydrocarbons is doubtful.

(b.) *From Tri-olein*.—For the better investigation of these products a quantity of 6 kilos. was subjected to distillation. The resulting oil differed from that obtained from the fish oil in respect of specific gravity, which is 0.780; the lower gravity being probably due to a lesser proportion of unsaturated hydrocarbons. The authors isolated from this product some hydrocarbons of the methane series, *e.g.*, normal hexane and heptane, concluding as the result of their investigation a general similarity of the constituents of this oil to those of the product described under (a.).

Composition of the Gaseous Products of the Distillation.
—The mean composition of the gaseous mixture evolved in the experiments in the sealed glass tubes was found to be as below:—

	Per Cent.
Carbonic anhydride.....	17.4
Olefines.....	7.8
Carbonic oxide.....	34.5
Methane.....	38.3
Residue (difference)	2.0

The gases evolved under the condition of distillation at the ordinary atmospheric pressure are differently proportioned. The following numbers express the mean composition of the mixture:—

	Per Cent.
Carbonic anhydride	26.7
Olefines.....	11.4
Carbonic oxide.....	31.9
Methane.....	25.2
Residue (difference)	1.8

The increase of the methane at the expense of the carbonic anhydride, under the condition of distillation under pressure, is noteworthy. This result was confirmed by comparative distillations of oleic acid under the two sets of conditions; the gaseous mixtures evolved being analysed with the following results:—

	Burner.	Specific Gravity.	Flashing Point.	Mean Luminosity.	Consumption per Candle per Hour.
Artificial petroleum from fish oil.....	{ a } { b }	0.8025	26.5	{ 13.2 } { 9.2 }	2.32 2.44
Pennsylvanian petroleum.....	{ a } { b }	0.8034	25.0	{ 8.56 } { 7.78 }	4.6 3.65

The luminous effect of the artificial petroleum is high with a relatively low consumption of oil.

In conclusion, the authors discuss the bearings of their researches upon the problem of the natural origin of the petroleum. They afford as yet only approximations to the proof of their theory of the "animal" origin of the mineral oils.

From experiments on the destructive distillation of mussels, the authors conclude that the pyrogenetic process—which they assume—must have preceded in geologic time by fermentation at the expense of the nitrogenous constituents, and an accumulation of the residual fatty components of the animal bodies.—C. F. C.

IV.—COLOURING MATTERS AND DYES.

Thioflavin. A. Schenrer. Soc. Ind. de Mulhouse. Sitzungsber. May 8 and 22, 1889.

This is a new basic yellow colouring matter made by Casella and Co. It is soluble in water and alcohol and very soluble in acetone, acetic acid, and acetic acid. It is easily fixed with a tannin mordant. Good results are obtained on cotton by the following process:—40 parts of thioflavin, 50 of tannin, 50 of water, 100 of acetic acid, 60 of acetic acid, and 700 of gum solution are taken. The goods after treatment are steamed and passed through tartar-emetic. Thioflavin thus yields a fast and bright yellow comparable with chromate of lead, and possesses moreover the valuable property of not running into the white of the fabric in printing. Its fastness to light is about equal to that of vat-indigo. Schenrer pronounces this yellow dyestuff superior to all other yellow dyes that are fixed by tannin. It is derived

	High Pressure.	Atmospheric Pressure.
Carbonic anhydride.....	26.0	37.2
Olefines.....	2.9	12.5
Carbonic oxide.....	23.5	38.6
Methane.....	43.6	9.3
Residue (difference)	2.0	2.4

Illuminating Oil from the Products of Distillation.—The crude product from the distillation of the fish oil was redistilled, and the portion distilling between 140°—300°, amounting to about 60 per cent. of the original, separately collected and purified by agitating successively with dilute sulphuric acid, water, and soda-lye.

This purified oil—the authors' artificial petroleum—was nearly colourless, with a pale blue fluorescence, specific gravity 0.8025, flashing point 26.5° (Abel), specific viscosity 1.006 (water 1.0). The latter number is noteworthy, being sensibly less than for the natural petroleum.

The following are the details of photometric comparisons of the artificial with Pennsylvanian petroleum, the burners employed being—(a) Schuster and Baer's. (b) Wild and Wersel's. The standard of luminosity was the German normal paraffin candle.

from a class of new yellow dyestuffs consisting of the ethylated or methylated derivatives of dehydrothiitoluidine (Dahl's). (See Jour. Soc. Dyers and Colourists, 1889, 107.)
—W. S.

On the Constitution of Primidine. W. Pfitzinger and L. Gattermann. Ber. 22, 1063—1068.

ACCORDING TO GREEN the constitution of dehydrothiitoluidine is—

The authors, however, contend that the formula—

explains far more satisfactorily the properties of this base. By diazotising the base and boiling its alcoholic solution a body is obtained, crystallising in long colourless needles, melting at 122° C. It has to be considered as *Benzoyl p-m-Amidothiocresol*—

belonging to the class which Hofmann obtained by treating acid anilides with sulphur, or which were prepared by Jacobsen by oxidising thioanilides with potassium ferri-cyanide.

Hess has obtained a body from *p-m-amidothiocresol* identical in every respect with the above, and the authors further prepared synthetically the same compound according to Jacobsen's method. Thiobenzotoluidine, melting at 188° C., dissolved in caustic soda, was poured into a solution

of potassium ferrieyanide. A precipitate separated which, after recrystallisation from dilute alcohol, melted at 122° C., and was in every respect identical with benzenyl-*p*-*m*-amidodihydroresol from dehydrothiitoluidine.

By melting this compound with caustic potash the following reaction ought to take place:—

When 2.3 grms. of the purified compound were added to 5 grms. of fused caustic potash, it was after some time dissolved, the mixture suddenly solidifying. From its clear aqueous solution hydrochloric acid precipitates a colourless crystalline body, melting, after purification, at 122.5° C., which was proved to be benzoic acid. The hydrochloric acid solution was precipitated by sodium bicarbonate, and a crystalline compound was thus obtained, which, however, rapidly decomposed. It was therefore converted by nitrous acid into its diazosulphide, crystallising from petroleum spirit in large plates, melting at 42°–43° C., and identical with a body recently obtained by Jacobsen and Ney of the formula—

* Dehydrothiitoluidine itself ought to yield under similar treatment paramidobenzoic acid and *p*-*m*-amidodihydroresol—

Experiments proved this hypothesis to be quite correct.

When the primuline base itself is fused with caustic potash at 250°–270° C., and its aqueous solution, after acidulation with hydrochloric acid, is treated with nitrous acid, a considerable quantity of a yellow precipitate is formed which was separated by filtration. The filtrate yielded with an alkaline solution of β-naphthol a yellowish-red colouring matter, and contained probably diazoparamidobenzoic acid. The residue consisted of two bodies, one soluble and one insoluble in carbonate of soda. The latter proved to be the before-described diazosulphide, melting at 42°–43° C. The former is, perhaps, the carbonic acid of the phenylenediazosulphide. The primuline base probably owes its existence to the combination of two molecules of dehydrothiitoluidine—

or to the combination of one molecule of dehydrothiitoluidine with one molecule of paratoluidine—

The authors will continue the research, and endeavour to decide which is the correct interpretation of this compound.

—A. L.

On Azo Compounds from Salicylic Aldehyde, Salicylic Alcohol, and Salicylic Amide. E. Tummey. Ann. 251, 174–187.

P-Azobenzene sulphonic acid, salicylic aldehyde—

was obtained in the usual way; it melted at 232°–235° C. With hydroxylamine and phenylhydrazine it forms the compounds characteristic of the aldehydes. Bromine decomposes it and produces diazosulphanilic acid and dibromosalicylic aldehyde, melting at 85° C. The author prepared further:—

M-Azobenzene sulphonic acid, salicylic aldehyde, melting above 270° C.

Azobenzene salicylic aldehyde melting at 128° C.

Azobenzene salicylic alcohol—

melting at 143°–144° C.

Azobenzene salicylic amide—

melting at 235° C.

P-Azobenzene sulphonic acid, salicylic amide.—A. L.

On Azo Compounds of Salicylic Acid. L. Gebeck. Ann. 251, 188–196.

Azonitrobenzene salicylic acid—

melting at 237° C., was obtained from meta-nitraniline and salicylic acid.

Azonitrobenzene salicylic methyl ether—

yellow needles, melting at 167° C.

Azonitrobenzene salicylic ethylether orange needles melting at 186° C.

Azonitrobenzene benzoylsalicylic acid—

yellow needles, melting above 240° C.

If azonitrobenzene salicylic acid be reduced in alkaline solution with zinc dust *Hydrazoaniline*, $\text{C}_2\text{H}_5\text{N}_2$, melting at 111° C., is formed. On heating azonitrobenzene salicylic acid with aniline a compound, $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_3(\text{C}_6\text{H}_5)(\text{NHC}_6\text{H}_5)$, is formed, crystallising in red-brown needles melting at 197° C.

Alpha-azonaphthalene salicylic acid, yellow needles, melting at 212° C. On heating with aniline a body of the formula $\text{C}_{10}\text{H}_7\text{N}_2\text{C}_6\text{H}_3(\text{C}_6\text{H}_5)(\text{NHC}_6\text{H}_5)$ is formed, forming in benzene solution red-brown crystals melting at 197° C.

Beta-azonaphthalene salicylic acid, small yellow needles, melting at 233° C. On boiling with aniline a body of the formula $\text{C}_{10}\text{H}_7\text{N}_2\text{C}_6\text{H}_3(\text{C}_6\text{H}_5)(\text{NHC}_6\text{H}_5)$ is obtained, crystallising from benzene in brown plates which melt at 236° C.

—A. L.

On α-Naphthol Sulphonic Acids. F. Bender. Ber. 22, 993–1,000.

The following sulphonic acids have been hitherto obtained from α-naphthol:—

(1.) Monosulphonic acid of Schäffer and Baum. (2.) So-called α-naphthol-α-sulphonic acid prepared also from naphthionic acid. (3.) Liebmann's monosulphonic acid. (4.) Disulphonic acid, yielding dinitronaphthol on nitration. (5.) Disulphonic acid, which can be nitrosated, and is capable of yielding azo-dyes. (6.) Trisulphonic acid of the Badische Anilin und Soda Fabrik.

Nos. 1 and 2 combine with diazo-compounds, form dinitronaphthol, and well crystallising nitroso-derivatives, which on nitration yield dinitronaphthol.

No. 3 forms azo- and diazo-colouring matters—on nitration comparatively little dinitronaphthol sulphonic acid is formed; the nitroso-compound crystallises well, and produces on nitration dinitronaphthol sulphonic acid.

No. 4 yields neither azo- nor nitroso-compounds; on nitration dinitronaphthol is formed.

No. 5 produces azo-compounds and nitroso-compounds; on nitration dinitronaphthol sulphonic acid is formed as with Liebmann's acid; the nitroso-compound, however, can be easily nitrated.

No. 6 forms neither azo- nor nitroso-compounds; on nitration dinitronaphthol sulphonic acid is formed.

The disulphonic acid No. 4 must have the constitution $[\text{OH}:\text{SO}_3\text{H}:\text{SO}_3\text{H} = 1:2:4]$.

By boiling with acid two monosulphonic acids are formed, identical with No. 1 and No. 2. Schäffer's monosulphonic acid like α-nitroso-α-naphthol does not form a

green colouring matter with ferric chloride and nitrous acid, and contains therefore the sulphonic group in the position 2, while α -naphthol- α -monosulphonic acid under the same conditions does yield a green colouring matter, and has to be considered as the "4" monosulphonic acid. The action of nitrous acid, nitric acid, and diazo-compounds on the different naphthol sulphonic acids renders it possible to analyse mixtures of them without any further separation. Such a mixture is converted into the calcium salts, acidulated, and a nitrated solution of a nitrite is added, until nitrous acid is not any more absorbed after standing for some time. Or a solution of diazoxyline is added until a sample after acidulation with sulphuric acid, precipitation with salt, and filtration does not form any more colouring matter with diazoxyline. Thus it is found how much of the α -naphthol has been converted into sulphonic acids, yielding nitroso- and azo-compounds.

Titration with diazoxyline may lead to mistakes when Liebmann's acid is present, as it combines with two molecules of the diazo-compound.

The acids which can be thus estimated are 1, 2, 3, and 5. There remain 4 and 6, and to separate these, the filtrate from the xyldine colour is nitrated, and the quantities of dinitronaphthol and dinitronaphthol sulphonic acid are estimated. To decide whether Nos. 1 and 2 are present with 5, the nitroso-derivatives of the calcium or barium salts are nitrated, and the quantities of dinitronaphthol and dinitronaphthol sulphonic acid are estimated. If, furthermore, the difference in the yield of dinitronaphthol and its sulphonic acid compounds obtained once by nitrating the whole mixture; secondly, by first removing the sulphonic acids capable of forming azo-dyes, be known, the quantities of Nos. 1, 2, and 5 can be readily estimated.

The following are the results of a great many experiments on the sulphonation of α -naphthol. The monosulphonic acids Nos. 1 and 2 disappear rapidly. Even following Schäffer's method, the disulphonic acid No. 4 is formed.

On using an excess of strong (especially fuming) sulphuric acid, the sulphonation proceeds in the following manner:—

Monosulphonic acid (Nos. 1, 2), disulphonic acid (4), trisulphonic acid (6), disulphonic acid (5).

On using little ordinary sulphuric acid, only little trisulphonic acid is formed, but the disulphonic acid (4) is changed into the isomeric compound (5).

Monosulphonic acid (1), (2), disulphonic acid (4), disulphonic acid (5). On heating strongly, the disulphonic acid is changed into the monosulphonic acid (3), decomposition taking place and sulphurous acid escaping.—A. L.

Synthesis of Rosanilines from Aromatic Amines by the Action of Substances yielding Halogens. O. Mühlhäuser. Dingl. Polyt. J. **272**, 376—382.

AFTER discussing the cases in which mixtures of different aromatic amines are capable of yielding rosanilines, having regard to the constitution of the former, the author gives various tables showing the action of halogens, metallic and metalloïd halogen compounds, and bodies producing halogens as dehydrating agents in the formation of these dyes. The tables, which are too extensive to be reproduced here, show the case in which any one of these dehydrating agents acts on a given mixture of different amines with production of rosanilines.

As regards the metallic chlorides their action often consists in giving up part of their chlorine. Thus SnCl_4 becomes SnCl_2 , and CuCl_2 becomes CuCl . In the class of metalloïd halogen compounds suitable for the above purposes, carbon hexachloride is the most important, C_2Cl_4 and CHCl_3 being also used. Again, mixtures of hydrochloric acid with weak oxidising agents, e.g., ferriyanide, ferric oxide, &c. are suitable; here, of course, it is the halogen set at liberty which acts as the condensing medium.

An explanation is given of the manner in which halogen-carriers effect condensations. Ferrous chloride, which is pre-eminently suited for these purposes, is said to generate chlorine in presence of HCl and nitrobenzene; ferric chloride is formed which yields part of its chlorine to the aromatic base, and this process is repeated so long as

nitrobenzene remains in the mixture. Finally, the author illustrates by means of several equations the changes which he believes to take place in the above processes. Thus, in the formation of pararosauiline he formulates the following phases—

—A. R.

PATENTS.

The Manufacture of Diethylmercaptol and of a Sulphone therefrom. T. J. Johnson, London. From The Farbenfabrik vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 12,563, August 31, 1888. 4d.

THE patent describes the production of diethylsulphone diethylmethane by oxidising the product obtained by condensing diethylketone with ethylmercaptan by means of hydrochloric or sulphuric acid. 14 kilos. of ethylmercaptan and 10 kilos. of diethylketone are saturated with dry hydrochloric acid gas, the mixture being cooled by water or ice. The formation of the mercaptol is completed in a few hours. On the addition of water it separates as an oil and is purified by washing with sodium hydrate, drying with calcium chloride and rectification in vacuo. It boils at 225° — 230°C . and possesses a strong odour. To convert it into the sulphone, 1 kilo. is dissolved in 50 kilos. of water and a solution containing 4 kilos. of permanganate, 1 kilo. of concentrated sulphuric acid, and 80 kilos. of water, is slowly added. The oxidation is complete when the solution becomes colourless. The filtrate on evaporation yields the diethylsulphone diethylmethane in the form of silvery scales, melting at 87° — 89°C . The product is tasteless and odourless, slightly soluble in cold water, but readily soluble in hot water, ether, alcohol, and similar solvents.—T. A. L.

Improvements in the Manufacture of Colouring Matters. O. Huray, London. From G. C. Zimmer, Mannheim, Germany. Eng. Pat. 13,798, September 24, 1888. 6d.

PHENYL- β -NAPHTHYLAMINE monosulphonic acid (Merz and Weith, Ber. **13**, 1300), when combined with tetrazo-diphenyl or tetrazo-ditolyl, yields colouring matters which dye unmordanted cotton blue shades of red. The operation is effected in two stages. One molecule of the tetrazo salt is combined with one molecule of the monosulphonic acid above mentioned, forming an insoluble compound. This is then combined either with a second molecule of the sulphonic acid or with a phenol or amine or with their sulphonic or carboxylic acids. The following are some examples given. 28 kilos. of benzidine sulphate are diazotised in 600 litres of water with 14 kilos. of sodium nitrite and 40 kilos. of hydrochloric acid. This solution is then poured into 600 litres of water containing 32 kilos. of phenyl- β -naphthylamine sodium sulphonate and 35 kilos. of sodium acetate. The brown intermediate product thus formed is added to 26 kilos. of sodium naphthionate and 10 kilos. of sodium carbonate dissolved in 900 litres of water. The whole is then agitated for 12 hours, boiled, filtered, and the colouring matter salted out. It dyes cotton a bluish-red. By substituting 31 kilos. of tolidine sulphate for the benzidine, a much bluer colour is produced. A bluish-violet colouring matter is formed by reacting with the intermediate compound described above on β -naphthol disulphonic acid (R salt) in an alkaline solution, and a still bluer colouring matter is obtained by employing α -naphthol- α -sulphonic acid in place of the R salt.—T. A. L.

Improvements in and relating to Colouring Matters.

H. H. Leigh, London. From R. G. Williams, Albany, New York, U.S.A. Eng. Pat. 4565, March 15, 1889. 6d.

ONE molecule of a tetrazo compound of diphenyl, ditolyl, dixyl, stilbene, fluorene, naphthalene, or their sulphonic acids, is combined with one molecule of one of the present known sulphonic acids of naphthylamine, and the intermediate compound thus formed is combined with one molecule of an alkylised oreinol or its sulphonic acid, or with one molecule of the product which is formed by combining oreinol with sodium chloride (Watts, VI., 885; De Luyne, Zeits. für Chemie, [2], IV., 703). This compound is formed by saturating a 5 per cent. solution of oreinol with salt, slightly acidulating it with hydrochloric acid and boiling the solution until it shows a green fluorescence on the addition of soda. The solution is filtered from tar and is ready for use. The derivatives of oreinol employed are the mono-, di-, or tri-methyl, ethyl, amyl, or acetyl oreinols. The method of working is similar to that usually employed, and the colouring matters produced belong to the Congo red and benzopurpurine class.—T. A. L.

The Production of Azo-Colouring Matters from Diamidobenzylbenzidine and Diamidobenzyltolidine. A. Bang, Leeds. From Dahl and Co., Barmen, Germany. Eng. Pat. 7587, May 7, 1889. 4d.

DIAMIDODIBENZYL BENZIDINE and diamidodibenzyltolidine yield tetrazo derivatives by the action of nitrous acid. When these are combined with naphthionic acid or with β -naphthylamine- β -sulphonic acid, bluish-red dyestuffs are produced, with β -naphthylamine- β -sulphonic acid an orange dyestuff, and with a mixture of the latter and naphthionic acid a scarlet is formed. 42.2 kilos. of diamidodibenzyltolidine are diazotised with 60 kilos. of hydrochloric acid and 14 kilos. of sodium nitrite, and slowly added to a solution of 21.4 kilos. of sodium naphthionate and 40 kilos. of sodium acetate. The formation of the intermediate compound takes about one hour and at the end of this time a solution of 24.4 kilos. of sodium β -naphthylamine- β -sulphonic acid is run in and the mixture allowed to stand eight days, during which time it must be frequently stirred. The mixture is then neutralised with soda and the colouring matter salted out, filter-pressed and dried.

—T. A. L.

The Production of Paranitrobenzylsulpho Acid and also Azo-Colouring Matters from the Amidobenzylsulpho Acid corresponding to this Nitro-Compound. A. Bang, Leeds. From Dahl and Co., Barmen, Germany. Eng. Pat. 7588, May 7, 1889. 4d.

IF *p*-nitrobenzylechloride be heated with neutral sodium sulphite it is converted into *p*-nitrobenzylsulphonic acid. 17.1 kilos. of *p*-nitrobenzylechloride and 25.5 kilos. of sodium sulphite are heated for two days with 30 kilos. of water in an enamelled boiler provided with a reflux condenser. At the end of this time a yellowish solution results, which on cooling deposits crystals of sodium nitrobenzylsulphonate. This is purified by recrystallisation and yields on reduction the corresponding amido-compound, which hitherto has not been used for the production of dyestuffs. It combines with tetrazo salts, forming dyestuffs whose dye-baths are exhausted by unmodified cotton. Various combinations can be made, of which the following is an example. 18.4 kilos. of benzidine or an equivalent amount of tolidine, diamidostilbene, or diamidostilbene sulphonic acid are diazotised with 60 kilos. of hydrochloric acid and 14 kilos. of sodium nitrite and added to a solution of *p*-amidobenzylsulphonate of sodium and 14 kilos. of sodium acetate. To this intermediate product is then added a solution containing 24.6 kilos. of sodium naphthionate and the mixture is allowed to stand eight days, then neutralised with soda and the dyestuff precipitated with salt, filter-pressed and dried. The same compound may also be formed by combining the tetrazo derivative first with naphthionic acid and afterwards with *p*-amidobenzylsulphonic acid.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENT.

Improvements in Treatment of Sisal Hemp and Analogous Fibres for Textile Purposes. A. W. Montgomery, New York, U.S.A. Eng. Pat. 5582, April 2, 1889. 6d.

THE inventor claims "cleaning sisal and analogous fibres and preparing the same for spinning after the ultimate fibres have been separated from each other, and the preliminary cleaning effected, which consists in combing or heckling said fibres to remove the remaining foreign adhering matter before oil has been applied thereto and of subsequently oiling said fibre." By this means a saving of oil is effected and an improved quality of fibre is obtained.

—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Dyed Artificial Silk from Pyroxylin. H. Koechlin, Soc. Ind. de Mulhouse Sitzungsber. May 8 and 22, 1889.

A SAMPLE of the new artificial silk (this Journal, 1889, 539) dyed with rhodamine was exhibited. It possessed more gloss and beauty than silk. The new textile fibre is made in Lyons by a patented process (Ger. Pat. 38, 368). According to Koechlin's description the solution of pyroxylin is pressed through narrow apertures of the diameter of silk threads, and the fibres are then agitated in water, by which a kind of coagulation is effected. The material is then partially denitrated. It possesses the same lustre as silk, but is stated by Koechlin to show a less degree of tenacity.—W. S.

Notes on Lead in Water. C. Rawson. J. Soc. Dyers and Colourists, 5, 58—61.

A SERIES of dyeing experiments were made on wool with a few of the brighter coal-tar colours and on indigo, with a view of ascertaining the effect of small quantities of lead in the water used. For further details of the experiments see page 638.

Observations relating to Indigo Dyeing by the Hydrosulphite Process. D. Dawson. J. Soc. Dyers and Colourists, 5, 93—98.

THE author advocates an analytical examination of the ingredients for making up a hydrosulphite vat, in order to attain to greater certainty in the results. He finds that only free sulphurous acid will react with zinc to produce hydrosulphite, and consequently an equivalent of sulphuric acid should be used along with sodium bisulphite in order to liberate all the sulphurous acid. For the estimation of the reducing power of a hydrosulphite solution the preference is given to titration with a solution of sulphindigotic acid. The acidity of the sodium bisulphite solution is ascertained by the quantity of carbonic acid evolved on treatment with sodium bicarbonate, and the total sulphurous acid present is estimated by titration with bichromate solution.

In the discussion following the reading of the paper, it was pointed out that the shade of colour given by the hydrosulphite vat differs from that given by the wood vat or the ferrous sulphate vat, and that this difference results from the destruction of the red constituent of ordinary indigo by the action of the hydrosulphite vat; but the hydrosulphite method offers advantages, such as ease of manipulation and a greater exhaustion of the bath, by which it is able to supersede the old processes in many cases. An alternative method of examining sodium bisulphite, and one which is capable of very accurate results, is

to titrate with standard solutions of acid and alkali, using on the one hand methyl orange as indicator, and on the other phenolphthalein. "With methyl orange as indicator bisulphite of soda is the neutral salt, but with phenolphthalein it is normal sulphite of soda."—G. H. B.

"Antimony Salt" as a Substitute for Tartar-Emetic.
D. Paterson. J. Soc. Dyers and Colourists, 5, 78—79.

This salt, possessing the composition $\text{SbF}_3 + (\text{NH}_4)_2\text{SO}_4$, is one of the new group of antimony-fluoride double salts discovered by E. de Haën (see this Journal, 1887, 727; 1888, 206, 207, 566, 624, 841). There are two groups of crystallised combinations, the constitution of which will be understood from the formulae:—

Chloride Group—

Sulphate Group—

The last mentioned salt is the one employed, as it possesses greater advantages for dyeing and printing purposes than any of the others, and is now being extensively used as a substitute for tartar-emicetic or oxalate of antimony. It is very poisonous and must be kept in wooden or clean copper vessels, as it attacks earthenware or glass. The goods are mordanted with sumac, gall nuts, or tannic acid as with tartar-emicetic, then they are passed through the solution of the salt; for 1 kilo. of tartar-emicetic only 0.9 kilo. of antimony salt is used, and for 1 kilo. of antimony oxalate only 0.5 kilo. of antimony salt is required. For experimental dyeing, 40 grains (*sic*) of antimony salt and 10 grains of soda crystals to the litre of water are sufficient. More brilliant colours are obtained by the use of the new substance, and its ready solubility is advantageous. Compared with tartar-emicetic its use effects a saving of 48 per cent.—G. H. B.

Industrial Position of Hydrogen Peroxide. C. F. Göhring.
Chem. Zeit. 13, 560—561.

HYDROGEN peroxide is now employed for bleaching silk, feathers, hair, ivory, bones, bristles, &c., and will doubtless soon be used for bleaching wool, and, if it was cheaper, even cotton.

For bleaching delicate materials, such as wool, feathers, &c., it should not be too strong; a solution of 1 in 10 is strong enough, and a bleaching vat of this solution may be used for quite a long time if the strength be kept up by fresh additions of hydrogen peroxide. The purer the peroxide is the better it will work, and care should be taken to avoid the presence of things which decompose it and, of course, render it useless, such as metals, even a nail, iron rust, &c. The strength of a solution is very easily estimated by titration with permanganate. As a general disinfectant it is not convenient, but is suitable for distribution as spray in sick rooms.—D. A. L.

Dyewoods and Extracts; their Use and Abuse. L. Bruchl.
Textile Colourist, 1889, No. 114 *et seq.*

AN industry of no small dimensions has been developed in the course of the past 20 years, the object of which is to extract the important active substances contained in the dyewoods, and thus to reduce the latter to a more convenient form. Owing to their easier application, the dyewood extracts have gradually gained numerous friends, and their employment has increased accordingly. Paradoxical as it may seem, a distinct line of demarcation cannot be drawn between the dyewood extracts and the tanning extracts, since many tanning materials are at the same time dyestuffs used in dyeing and printing, such as quercitron, sumac, and catechu. The property of the tannic acids to give coloured precipitates with metallic oxides, and, on the other hand, to precipitate artificial dyestuffs, either alone or in their combinations as metallic tannates, and thus

to act as simple or compound mordants, has caused them to be introduced into the dyeing and printing industries.

Since the value of such tanning and dyeing materials depends upon the quantity and quality of the tannic acids contained in them, it is important for the practical man to know the properties of these tannins. But it is to be regretted that science has not yet advanced far enough to speak with accurate knowledge of the tannic acids. Contradictory opinions are universally maintained. Tannic acid itself never serves for the manufacture of leather, because it is no tanning substance at all, being capable of forming simill-leather products, but not real leather. The employment of tannic acid is reserved for the dyeing and printing industries, together with some others.

Tannic acid has thus far only been manufactured from nut-galls. The value of tanning materials and of some dyeing substances being determined by the quantity of tannic acid contained therein, and the tannic acid of nut-galls (actual percentage of tannin) being accepted as a standard, it is evidently of importance to exactly know the constitution of tannic acid. But on this point the opinions of chemists are widely divergent. If we compare all the literature published on tannin matters, we come finally to the conclusion that there must be very different kinds of tannin. Whether the behaviour of all these tannins towards metallic salts, glue, animal skins, permanganate of potash, &c. be the same, we do not know whether the densities or the aqueous solutions of these tannins correspond or not. It can only be said that as long as "tannin" can only be understood as a collective name, it is absolutely inadmissible to take "chemically pure tannic acid" for the starting point if for the determination of the quantity of tannin in dyeing and tanning materials.

The high percentage of so-called active tannin cannot always be a gauge for the value of an extract or dyeing material.

The author divides the dyewoods into two groups, viz., (a), such as are principally useful on account of the colouring matters contained in them; (b), such as are used on account of their tannin as well as their colouring matter. To the former belong logwood, brazilwood, fustic, &c.; to the latter, quercitron and sumac.

LOGWOOD.

In text-books, even such as have been published by prominent authorities, as well as in the practice, we often find the statement made that the name of the wood is at once the criterion of its value, and thus the brands San Domingo, Yucatan, Monte Christo, and Laguna are generally considered the best, and the others are described as of inferior value. The author found this not to be a correct proceeding, as shown in the following table:—

Name and Mark of Woods.	Per-centage of Water.	Per-centage of Ashes.	Per-centage of Yield of Extract.	Per-centage of Combustible Matter.
Yucatan logwood	13.00	1.09	20.20	65.71
Laguna logwood'	12.38	0.96	21.00	65.66
Domingo logwood,	13.19	1.88	14.02	70.73
Monte Christo logwood, 1884	13.20	2.94	18.75	65.11
Monte Christo logwood, 1887	14.70	1.03	14.00	70.27
Fort Liberté logwood, 1886—87	13.10	0.82	20.33	65.75
Fort Liberté logwood, 1887	10.12	0.88	16.00	73.00
Fort Liberté logwood, 1885—86	12.11	2.03	17.45	68.41
Fort Liberté logwood, J.B., 1887	11.84	1.03	18.00	69.13
Yucatan logwood, E.J. ...	14.51	1.20	17.34	66.95
Domingo logwood, D. ...	13.71	2.14	19.30	64.85
Jamaica wood	14.10	1.14	18.70	66.06
Jamaica wood	12.70	1.30	18.00	68.60
Jamaica wood roots	15.30	2.30	10.70	71.70

The value of a dyewood depends upon the quantity of colouring matter contained in the wood. Ordinarily, the manufacturer of extracts takes the yield of extract as the gauge of value of the wood, and the same opinion prevails in the analyses of several chemists, and with numerous dyers, who boil out their bought wood, and judge it by the specific gravity of their decoctions. This largely adopted opinion seems the more peculiar, as there is an essay of Chevreul's extant since 1810, showing that the yield of extract from the wood is not identical with its tinctorial value. Besides variable quantities of colouring matter, there are also organic and mineral substances variably present in logwood. It follows from this that these substances are present in the extracts obtained and thus increase the quantity but not the tinctorial value of the latter. The colouring matter of logwood is present: first, in an oxidised state; second, as hæmatestin and hæmatoxylin; third, as glucoside. The oxidised portion is produced by the alteration of the wood in the air, which causes the dark colouring of the woods and of the decoctions. This oxidation may have proceeded more or less far; from some wood decoctions common salt precipitates a resinous black substance, whilst with other decoctions the precipitates are only of a light brick red colour. This oxidation of the dyewood in the air extends not only to the transformation of hæmatestin and hæmatoxylin into higher grades of oxidation, but to the glucosides also, which are thereby partly converted into hæmatoxylin and hæmatestin and the higher grades of oxidation, and thus first assume the colouring character of a dyestuff. In estimating the quality of a wood, the only rational way is to take the actual quantity of colouring matter present into consideration, and not the total extract. This basis of valuation, however, is not adopted by all manufacturers of extract and numerous dyers for want of knowledge. The author found that the so-called low grades of logwood (such as those from Jamaica) are sometimes worth more than prime San Domingo and Monte Christo logwoods, and that even with equal yields of extract, one wood may have a greater tinctorial value than another. It is advisable, therefore, for the dyer, as well as for any consumer of logwood, to examine the article offered and not to allow himself to be deceived by high-sounding names. In order to determine the tinctorial value of the extracts obtained from various classes of wood, the author made comparative dye trials, and found that a high yield does not correspond to a high tinctorial value. He digested the extracts obtained, with ether, then with alcohol, took up the remaining insoluble residue with water, and made dyeing experiments with each extract. He thus found that the alcoholic and ethereal extracts were rich in colouring matter, while the residue taken up by water was the poorest, while that no more colouring matter could be detected in it by the most delicate reagents, and that it principally consisted of mineral compounds, sugars, and other organic—non-colouring—substances.

TABLE II.

Name and Mark of Woods.	Alcoholic Extract.	Ethereal Extract.	Residue	Yield of Extract.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Yucatan logwood	37.46	60.12	2.42	20.20
Laguna logwood	47.95	51.37	0.68	21.00
Domingo logwood	53.47	44.95	1.58	11.02
Dominzo logwood, O....	50.32	43.81	5.81	13.30
Monte Christo logwood, 1884.....	60.32	32.00	7.78	18.75
Monte Christo logwood, 1887.....	54.10	34.72	11.18	14.00

Fort Liberté logwood, 1887.....	47.92	50.00	2.18	16.06
Fort Liberté logwood, 1885-86.....	35.17	59.72	5.21	17.45
Fort Liberté logwood, J.B., 1887	34.81	59.24	5.95	18.00
Yucatan logwood, E.J....	38.51	58.34	3.15	17.34
Jamaica wood	50.50	42.20	6.30	18.70
Jamaica wood	50.71	43.05	6.24	18.00
Jamaica root-wood.....	30.12	52.99	16.89	10.70

The dyeing experiments with two brands of San Domingo wood (with 98.42 per cent. of colouring matter and 14 per cent. yield, and with 94.13 per cent. of colouring matter, and 19.30 per cent. yield) showed that the brand with 14 per cent. yield gave more favourable results than that with 19.30 per cent. yield. The two brands of Jamaica wood are nearly equal in yield and residue, as well as in the dyeing result, while Jamaica root-wood is much weaker, even when a quantity of wood corresponding with the extract yield is taken for dyeing (instead of 5 grms. of wood, 8.7 grms. of root-wood); the intensity of the dye only approaches the shade produced by 5 grms. of Jamaica wood when 14 grms. of root-wood are employed. If we calculate the quantity of wood of equal dyeing power according to the amount of insoluble residue, using 5 grms. of Jamaica wood, the calculation for root-wood will give the figure 13.55 grms., which comes very near the value ascertained practically at any rate, nearer than the figure 8.7 grms. as calculated from the yield of extract.

Another error constantly occurring in valuations of wood is that of taking the samples inaccurately. The samples presented to the chemist or dyer by the agents or dealers are mostly insufficient in quantity, and therefore unsuitable for ascertaining the actual value of the wood.

The author took from a lot of Fort Liberté logwood 10 samples of about 1 kilo. each, had them chipped, and determined their extract yields as follow:—

I.	II.	III.	IV.	V.
Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
21.3	18.35	15.7	18.4	16.1
VI.	VII.	VIII.	IX.	X.
Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
19.8	11.4	10.15	15.9	12.75

giving an average yield of 15.88 per cent. of extract. A sample of about 1 kilo. taken from a mass of about 20,000 kilos. of this cargo of wood (after chipping) gave a yield of 18.3 per cent. of extract; that is, much better than the average of the 10 samples of wood. On working up this wood on the large scale, the yield of extract was about 18 per cent. It is advisable, therefore, never to buy the supply on the strength of small samples, but always to judge the value of a wood according to the results obtained with a sample of at least 100 kilos. For the dyer, to whom the woods are almost exclusively offered in a chipped condition, the valuation by means of a small lot of about 100 kilos. is pretty sure; the consumer, however, who must buy the wood in the log, cannot be too cautious. The dyer is also often offered so-called oxidised or fermented dyewoods for sale, the price of such woods generally being somewhat higher than that of unfermented wood.

The fermentation or oxidation of the wood has for its object the transformation of the colouring matters of lower degrees of oxidation contained in logwood—such as hæmatoxylin and the glucosides—into bodies of higher degrees of oxidation—such as hæmatestin, &c. For this purpose the dyewoods are reduced to small fragments, chipped or ground, then wetted, and then exposed to the action of air and moisture in heaps of from $\frac{1}{2}$ to 1 metre in height. As soon as the reaction begins, heat is developed in the interior of the heaps, and in order to prevent over-oxidation, they must be at once turned over with the shovel. This operation is continued for several weeks, and the oxidation is considered complete when the glucosides and hæmatoxylin are entirely transformed into hæmatestin. This phase is marked by certain external appearances—such as a dark red colour of the wood after drying, with a light beetle-green lustre, and a wine-like odour of the wet wood. On boiling a sample of this wood with distilled water, the decoction must be dark straw-yellow, and turn claret-red on the addition of a trace of ammonia or sodium aluminate. When the colour strikes into blue, over-oxidation has already taken place, and the wood is of inferior

value. According to Schützenberger and the practical observation of English manufacturers, the oxidation process ought not to be continued longer than 6 to 8 weeks; for every 100 kilos. wood, 60 to 64 litres of water are to be used for moistening. The value of 6 lb. of logwood thus treated is equal to that of 10 lb. of newly chipped wood. In order to accelerate the oxidation, chemical reagents are sometimes dissolved in the water used for moistening, such as potassium chlorate and oxalic acid, ammonia, soda, ammonium phosphate, urine, potassium chromate, &c. The action of these reagents is tolerably strong, and can materially accelerate the oxidation, though at the cost of the quality of the dyewood. The yield of extract obtained from such oxidised woods is always higher than that of unoxidised woods, the shade in dyeing is deeper, but the fastness to washing and fulling, and resistance of the colours to light, are considerably diminished. By means of oxidising experiments executed at the same time, and as uniformly as possible, and by comparative dye-trials with the various products of oxidation, examining and exposing the dyed patterns for two minutes to the action of a chlorine bath (chloride of lime) at 0.05° B., and determining the yields of extract, the author arrived at the results shown in Table III. The table shows plainly in what ratio the tinctorial value or rather the extract yield of the wood increases by the employment of the oxidisers, but also the ratio of decrease in the fastness of the colours obtained to light and chlorine. While for a material which was dyed with unoxidised wood, 30 days were required to completely decolourise it, this result was already obtained in 18 days, in the case of wood which was simply oxidised by water and air. The shades obtained with oxidation products—oxidised by means of chalk, soda, and potassium chlorate—faded in ten days, and showed little resistance to chlorine. The poorest results were obtained with urine and potassium chromate; the latter, especially, oxidised the wood very quickly, so that in 8 or 12 days it was already almost completely oxidised, and the dyestuff very readily soluble in water, the wood thus obtained possessing all the properties which the dyer values; but the fastness to light and chlorine was extremely limited. Cotton yarn dyed black with this wood had the much-desired deep black tone, but, like the cotton cloth mordanted with alumina, it had become grey-yellow after an exposure to light of only five days. Urine gave similar results, and the same results were obtained by oxidation experiments with ammonium phosphate, silicate of soda, &c.

TABLE III.

Oxidising Agent.	Colour upon Alumina Mordant.	Yield of Extract per Cent.	Resistance to Light; Days.	Chlorine.
Unoxidised wood	Blue.	16.5	30	Un-changed.
Water and air	Blue.	17.8	18	Altered.
0.5 per cent. chalk	Violet blue.	18.4	10	Strongly altered.
0.25 per cent. potassium chlorate and oxalic acid	{ Violet } { blue. }	17.5	10	{ Strongly altered.
0.1 per cent. potassium chromate	{ Violet.	18.0	5	{ Dis-coloured.
0.25 per cent. soda'	Violet.	17.6	10	Strongly altered.
Urine	Violet blue.	18.0	8	Strongly altered.

The conclusion to be drawn from these experiments would be that a rational oxidation of the wood can at the best be effected by water and air, while oxidation by the agents enumerated is always effected at the cost of the fastness of the colour, and therefore objectionable.

Another method of oxidation worthy of notice is that by means of glue. This method is based upon the principle of precipitating the tannin-like compounds contained in

logwood by a solution of glue, and thus presenting the colouring matter pure, or purified, for use. Doubting the efficacy of glue, the author made experiments in this direction, and had his doubts confirmed. The compounds resembling tannin, which are present in some kinds of logwood, do not belong to the series of substances which are precipitated by glue, but are in their properties more similar to gallic acid, which is not precipitated by glue. The colouring matter itself, however, has a considerable affinity for glue; it is attracted by glue, although only in small quantities, mechanically as well as chemically, and is readily deposited from a decoction of the wood, on cooling, in the form of a flaky precipitate. The precipitation is promoted by the addition of a few drops of sulphuric acid. Dyeing experiments with wood oxidised by glue gave always slightly weaker results than with the same class of wood oxidised by water and air. The fastness to light and chlorine remained unaltered. This oxidising method is therefore, at least, a waste of glue. There are some kinds of logwood which contain traces of a tannin precipitable by glue, but the quantity of this tannin is so exceedingly small that its separation scarcely compensates for the colouring matter, which is at the same time precipitated by the glue.

In non-oxidised woods, if the latter are in good condition, the highest percentage of water which they contain is 15, while in freshly-oxidised and dried woods the minimum figure is always above 15 per cent., varying between 15 and 20 per cent. The method on which the dyer relies for examining his dyeing materials is that of dyeing patterns, the cotton piece goods dyer using prepared pieces of cotton cloth, the yarn dyer cotton yarn, and the wool dyer woollen piece goods or yarn. The examination upon prepared cotton piece goods is carried out as follows:—In a water or oil bath, which can be heated by steam or by gas-jets, are contained therein a number of tin-lined copper or glass beakers, of about 1 litre each capacity. Into these beakers equal quantities of the wood are introduced, say 0.5 gm., $\frac{1}{2}$ to $\frac{3}{4}$ litre water added, and a swatch of material entered, upon which stripes of alumina, iron, and a mixture of these two mordants have been printed, or a strip of material treated with iron mordant. Of such printed material a strip of the width of the piece and 10 cm. long is sufficient for 0.3 gm. to 0.5 gm. of wood; an equal piece of material mordanted with acetate of iron for black will do, but the quantity of wood must be regulated accordingly. Before entering, the swatches are moistened with water; after entering, the temperature of the dye-bath is raised, whilst briskly stirring, within one hour, to 75° C., and in another 15 minutes to the boiling point. For stripes the dyeing is then finished, but for black the dyeing is continued at the boil for about 10 minutes longer.

The dyed samples are now taken out, carefully washed, and dried in a drying chamber. By dyeing at the same time a sample with a wood of known quality for comparison, the value of the wood to be tested can be accurately determined to 1—2 per cent. by graduating the quantity of wood. This method of determining the tinctorial value will in most cases be satisfactory for the cotton dyer as well as the wool dyer. If, however, mordanted material cannot be had, the following method will give as satisfactory results:—

Enter 20 grms. of cotton yarn, bleached or unbleached, as convenient, into the beakers, with 5 grms. of wood for each, and boil for one hour, replacing the evaporated water with boiling water. Then take up the swatches from the baths, wring, shake off the adhering particles of wood (so that the liquid dripping off and the particles of wood fall back into the beakers) and enter the bath I. (for each sample of wood a separate mordant bath must be prepared)—viz., 1 litre cold water, 0.5 gm. copper sulphate; turn for five minutes, wring, shake out, and re-enter the dye-bath, to which 1 gm. of soda ash has been added, and boil for five minutes; then pass again into the copper mordant bath and the dye-bath (without adding more soda), boil for the same period, and enter bath II., consisting of 1 litre cold water and 0.8 gm. iron; turn for 10 minutes, wring, return to the dye-bath, to which now 1 gm. precipitated chalk has been added; boil for 15 minutes, lift, rinse, and dry. By comparing the shades obtained with various woods, their tinctorial value can thus be so accurately

determined that for an experiment on the large scale with the best kind of wood ascertained the basis is given. By this dyeing trial, which is not difficult to execute, the dyer can at all events protect himself from considerable losses in purchasing his stocks of logwood, as well as against the loss of a larger quantity of cotton, which would possibly occur in experimenting on a large scale.

Although it cannot be denied that the oxidation or fermentation of the wood offers several advantages, particularly when the wood is directly used in dyeing, the question of oxidation of the wood presents different features in so far as the manufacture of extracts is concerned. The manufacturer who furnishes his extracts to various branches of industry must also consider their wants, and the different purposes for which his extracts are used, and that in many cases an extract in which the dyestuff is oxidised to a high degree will not answer the purpose. A highly oxidised extract would, especially in printing woollen and textile fabrics, meet with little favour.

In the oxidation of the wood it cannot be avoided that (as is proved by the high extract yields), besides the oxidation of the dyestuff, transformations occur also with other substances contained in the wood, which greatly decrease their solubility in hot water, but which on the extract cooling down, as well as on adding chemical agents, are separated out. On boiling colours for printing, the inadaptability of highly-oxidised extracts manifests itself by the colours becoming gritty either immediately on cooling or in the colour boxes of the roller printing machines; the engraving of the rollers, plates, or blocks becomes clogged,

the print indistinct, and after continued use the colour coagulates and becomes watery. The author having made extensive experiments in this direction, found that extracts which had been purified by allowing them to settle showed a greater tendency to give coagulating colours than ordinary extracts do.

Every printwork chemist is aware that old colours never give good printing results, for the reason that the hæmato-metallic lake, which has already been formed in the colour, is present in the higher degrees of oxidation, and being but incompletely insoluble in acids cannot penetrate the fibre, and the colour being only superficially fixed upon the fibre in the steaming operation, has less power of resistance against washing, scouring and soaping operations, than a black which is developed from freshly-prepared colours.

If now the colouring matter of logwood is already present in the extract as hæmatein, and its higher degrees of oxidation not as glucoside convertible into hæmatein, in the preparation of colours, lakes of higher degrees of oxidation are produced from the beginning, which, in the first place, cause less fastness of the colour, and in the second place a clogging of the engravings, and, therefore, renders the colours or the extract less adaptable to printing purposes. Practical comparative experiments with differently prepared extracts have most completely confirmed this theoretical conclusion.

The author employed for the comparison extracts from the Jamaica brand taken from wood of the same cargo, shipped from the same place, and obtained the following results:—

Mode of Oxidation of Wood and Extracts.	Fastness to Light.	Fastness to Washing.	Fastness to Chlorine.	Remarks.
I.—Non-oxidised wood extract	25 days.	Good.	Normal.	Normal.
II.—Extract oxidised in the air	20 days.	Not as good as I.	Less so.	{ Soils the white of the tissues.
III.—Extract from wood oxidised in the air with water	20 days.	Ditto.	Ditto.	Ditto.
IV.—Extract from wood oxidised with chalk...	15 days.	Worse than I. and II.	Less than I. and II.	{ Soils the white of the tissues.
V.—Extract from wood oxidised with chrome } and potash	10 days.	Very little.	Less than II.	{ Colour readily coagulates.
VI.—Extract from wood oxidised with potas- sium chlorate and oxalic acid	10 days.	Ditto.	Ditto.	Ditto.
VII.—Extract from wood oxidised with urine...	10 days.	Ditto.	Ditto.	Ditto.

As in preparing the extracts used for these experiments with the colours, the greatest possible uniformity was observed, the results obtained prove the assertion that oxidised woods and their extracts, and extracts oxidised in the air, are less applicable to printing than non-oxidised extracts. Lakes and inks obtained with dyewood extracts will naturally be similar, the application of which is partly based upon the principle governing textile printing.

The previous oxidation of the wood is only to be recommended when the object is to produce dark extracts regardless of other properties.

On the other hand, by previous oxidation, the shades which the extracts can give with the various mordants are materially influenced. It is a fact known to every dyer that with some extracts of logwood, certain colours, especially pearl grey, are absolutely unobtainable, while by using another extract they are obtained exactly to shade. Comparative experiments which were made in this direction also proved that the previous oxidation of the wood, or the extracts, may modify the shade which the extract gives on dyeing with alumina, iron, copper, and mixed mordants. It is difficult to give names to the variety of shades obtained, but a sample-card plainly shows the numerous modifications, and it can only be said in general that with the same depth of shade the tones which oxidised extracts give with alumina mordants will always be violet—i.e., strike into red, and very much differ from the blue tone which is obtained by using non-oxidised wood extracts. Woods and extracts oxidised with

potassium chromate always give dyes which greatly resemble those produced with indigo substitute (which is easy to understand from the process of manufacturing indigo substitute). The same, or rather similar colours, are obtained on dyeing with extracts, if the wood or extract has been previously oxidised with chlorates or hypochlorites, such as chloride of lime. A deep blue tone is obtained with extracts in the preparation of which the wood was first oxidised with silicate of soda.

The assertion of many a dyer and printer, that he can only use a certain brand of extract, is not, therefore, to be ranked among the prejudices of which dyers often possess their share, but this assertion is justified, as has been seen, by the method of manufacturing extracts.

The principal adulterants of logwood extract are: molasses, dextrin, Glauber's salt, chalk, tannin extracts, such as chestnut, quebracho, sumac, divi-divi, and quercitron extracts, &c.

In liquid extracts, up to sp. gr. 1.256—1.312, Glauber's salt and chalk can be detected by the character of the sediment which always settles down from such extracts, and in which mostly a pulverulent deposit of chalk or of the sodium salt in crystals is found. For this reason these salts are only added in large quantities to solid extracts, and then usually along with other adulterants; besides, the colour of the solution and the constituents of the ash are sufficient indications by which to suspect the purity of the extract. Molasses and dextrin may be suspected if there is an abundant sediment, the former also if there is an increase of ash, and molasses can be discovered by the peculiar

odour, but in this errors are apt to be made. The author thinks that it is not safe to decide by the quantity of ash whether an extract is pure or adulterated, because there may occur highly adulterated extracts which yield a very small quantity of ash, while actually pure extract may give 5 to 8 per cent. ash. When dealing with the woods, it was shown that from the extracts prepared from some classes of wood upwards of 7.62 per cent. of ash was obtained, while from other woods the extract gave a result of only 1.08 per cent. of ash. In the same manner since the quantity of incinerable substance contained in an extract depends upon the class of the wood, the method of manufacturing the extract influences the quantity of ash. Extract works, whose filtering arrangements are imperfect, will invariably furnish extracts giving a higher percentage of ash. The following table shows the percentage of ash of extracts prepared from different woods by different methods:—

Name of Wood.	Extracted without Pressure in Extractor.	Extracted with $\frac{1}{2}$ Atmos. Pressure.	Extracted with $1\frac{1}{2}$ Atmos. Pressure.	Extracted with 10 Atmos. Pressure.
Yucatan wood	Per Cent. 1.98	Per Cent. 2.01	Per Cent. 2.74	Per Cent. 3.50
Laguna logwood ..	1.52	1.71	2.67	3.05
Fort Liberté logwood	1.08	1.09	1.84	2.15
Jamaica wood.....	2.33	2.35	2.94	3.72
San Domingo logwood	3.52	3.67	4.51	5.10
Monte Christo logwood.....	6.40	6.47	6.91	7.23
Jamaica root wood	7.02	7.70	8.10	8.51
Mixture of different woods	2.27	2.20	3.01	3.71

If it is possible, therefore, with these experimentally made extracts to obtain percentages of ash from the same class of wood, which range from 1.52 to 3.05 per cent., it is evident that in working on the large scale the difference must be still more considerable. From this table it will be seen that pure extracts obtained from different classes of wood can vary, as to their contents of incinerable substances, from 1.08 to 7.62 per cent.

The substances used as adulterants of extracts, such as molasses, greatly vary in the percentage of ash, and there are sugar molasses met with in commerce with only 8 per cent. ash, while others (osmotised molasses) show over 20 per cent. ash.

The detection of Glauber's salt and chalk does not belong to the most difficult problems for the analyst; different, however, is the question of the qualitative and quantitative determination of molasses and dextrin, which can only be determined on the basis of the proportion of sugar contained in these substances. Many methods have been suggested for the estimation of molasses, but the following seems to be most successful: 1—5 grms. of extract dried at 100° C. are extracted with absolute alcohol until a small quantity of the alcohol with sodium aluminate gives no longer any reaction with hæmatestin; the alcoholic extract is preserved. In the residue, besides the substances insoluble in alcohol which occur in extracts, there is contained the sugar of the molasses and dextrin originally present in the extract.

As a normal extract may contain 0.25—0.5 per cent. grape sugar, but never cane sugar, its detection in the residue after the alcoholic extraction is the surest proof of the presence of molasses; in the same manner, if there is a surplus of over $\frac{1}{2}$ to 1 per cent. starch sugar or grape sugar, the presence of a substance containing starch sugar or grape sugar may be inferred.

This method is used largely for the qualitative determination of saccharine matter in the extracts.

The alcoholic extract is now evaporated to dryness, the residue dried at 100° C., the mass obtained extracted with

ether, and the weight of the ethereal extract ascertained, the portion which is insoluble in ether being separately weighed. The comparison of these weights (etheral and alcoholic extracts) with those obtained by an examination of a pure, unadulterated logwood extract carried out in the same manner, shows whether there has also been an adulteration with chestnut extract. Chestnut extract yields to ether almost nothing, while it is readily soluble in alcohol; it is, therefore, easy to understand that, in the suspected extract, less substance soluble in ether and more substance soluble in alcohol is found than in pure, unadulterated extracts.

In order to ascertain if the suspected extract differs not only by the comparatively large quantity of matters soluble in alcohol, but also by their nature, from the pure extract, it now seems necessary to make the residues obtained by evaporation the subject of a direct comparative examination. For our purpose, however, this is unnecessary, since a comparative result is speedily arrived at by comparative dye trials. The products of the two extracts which are soluble in alcohol and in ether must, with equal weights, dye to the same shade equal surfaces of cotton cloth or equal weights of cotton, if they have the same composition. As regards the course of examination upon cotton cloth and tissues, the same tissues printed in stripes, as referred to when dealing with the woods, may be used, but for a tissue which is printed in stripes with different mordants, for each $10 \times 60 = 600$ sq. cm. of material, 0.1 gm. solid extract should be used; for the same quantity of material mordanted with acetate of iron 0.25—0.3 gm. extract is enough to obtain a good dyeing result. By comparative dye trials, made with the alcoholic and ethereal extraction products, the value of the extracts can, by graduation of this quantity, be accurately determined to 1—2 per cent.

A direct comparison of different extracts without previously extracting them with ether and alcohol, will not in all cases allow of an exact estimation of the extract. An accurate result will only be obtained if the adulterants are dextrin and molasses, Glauber's salt, &c.; but if admixtures containing tannin are present in the extracts, errors will always occur, which are caused by the colour reaction of the tannin with the mordants, and which may lead to entirely wrong conclusions regarding the value of the extract. In these cases it is recommended that a separation of the tannin from the colouring matter of the hæmatestin be effected (when extract of chestnut, quebracho or divi-divi is present) in the manner above stated, or, if this is not practicable, a dye trial upon yarn as described when dealing with the woods, be made, but with the addition to the dye-bath of extract of quercitron or sumac in the proportion of 25 per cent. of the quantity of extract. Since the tannic acid of sumac as well as of quercitron has a greater affinity for the mordanted fibre than the tannins of chestnut, quebracho and divi-divi extracts, the action of these tannins is thus minimised, and thus a more accurate valuation of the extract is rendered possible. Even in case of adulteration with sumac or quercitron (which seldom occurs on account of the price of the products), by the liberal addition of quercitron and sumac to the dye-bath a surplus of tannin is accumulated which the fibre is unable to absorb, so that in this case also the results will be more reliable.

Reliable results are also obtained by Trimble's colorimetric method, which is as follows:—A solution is prepared of 1 gm. of solid extract, dried at 100° C. in 1 litre of distilled water, and also one of 2 grms. sulphate of copper sulphate per litre of water. (Palmer states that it is found in practice necessary that the water for dilution should be three-fourths distilled water and one-fourth town's water, no doubt a trace of lime being necessary for the production of the blue lake of logwood and copper oxide.) Then 1 cm. of the extract solution is heated with 10 cm. water and 1 cm. copper solution, and quickly brought to boil, poured into a graduated cylinder, and filled up with distilled water to 100 cm. For this preparation a pure extract is to be used. The sample to be examined is treated in the same manner, and the liquid in a cylinder diluted with distilled water, until both liquids, when looked at from above, show exactly the same depth of colour. (Palmer (Textile Colourist, 11, 56) says the cylinders should be looked at at right angles to

the length of the cylinders. Results thus obtained are accurate to 2 per cent.) From the height of the column of liquid in the cylinder the value of the sample under examination is then easy to estimate. The test liquor must be renewed every ten minutes, because it rapidly changes in colour.

This method gives good results in the case of adulterants which do not react with copper salts; but when tannin-like adulterants are present, higher values will always result for the extract to be examined, because the tannin influences the colour reaction by the formation of a dark coloured tannate. If the molasses used for the adulteration is rich in salt, especially in carbonate of lime, an alteration of the reaction is also caused which may lead to wrong results. (The foregoing is contradicted by Palmer, *loc. cit.*) Although the enumerated methods cannot give accurate analytical results, yet with sufficient practice in examinations of extracts, and by the use of several methods, a pretty correct estimation of the quality and tinctorial value of an extract can be formed, which is in most cases sufficient for the practical colourist.

The addition of tannin extracts to logwood extracts, especially that of chestnut and quebracho extracts, is, apart from the undesirable alteration of the tone, injurious in so far as the colours are thereby rendered unfit for printing. Colours prepared with such extracts easily coagulate, besides the engravings of the printing rollers are clogged by the tannin of the chestnut and quebracho extracts, and the print indistinct despite the use of sharp doctors and brushes. If the addition is in considerable proportion, the colours coagulate on long standing; in some cases even (when the colours are strongly acid) upon the tissue, and the print runs or bleeds. The case is similar with quercitron and sumac, although not to the same extent. The addition of divi-divi to logwood extracts always causes bad impressions, and the doctors as well as printing rollers are scratched by such extracts.

Although molasses seems to be the most neutral addition, there are cases recorded where with an extract adulterated with 20 per cent. molasses, no black could be obtained. With molasses containing a high percentage of sugar, the sugar reduces the chlorates in steaming the goods, and, therefore, prevents the development of the colours. Besides, such colours stick in the engraving of the rollers, the colours upon the tissue dry badly, and the addition of molasses to logwood extracts therefore as regards printing colours gives rise to very justifiable complaints.

The impossibility of making an exact quantitative analysis of a logwood extract greatly favours the practice of adulterating extracts.

Another product is the commercial "hematein." This product is not, as the name would lead one to suppose, pure hematein, but a pulverulent extract, and that not always of the first quality. Under this name also products with 25–40 per cent. of admixtures are to be found. Since logwood extracts containing admixtures of extracts of chestnuts and sumac, molasses, &c., are hard to pulverise, and, if this should be successfully done, always gives a viscid and never a dry powder, either chalk or extract of quebracho is used for mixing the extract intended for hematein. Such extract dries very readily, and after pulverisation, has the light coffee-brown colour which is required for hematein.

EXTRACT OF FUSTIC.

This extract is mostly adulterated with dextrin, molasses, sulphate of zinc, glycerin, starch-sugar, alum, extract of turmeric, aniline dyestuffs, and nitroalizarin (Alizarin orange).

The determination of sulphate of zinc and of alum is pretty easy. The presence in the ash of alumina shows the adulteration with alum. The determination of sulphate of zinc, especially of small quantities, is more difficult, and the ash of the extract brought to a white heat will often cause errors. The presence of larger quantities of

this salt in extracts of fustic manifests itself by the turbidity of the extract solution.

Pure extract of fustic dissolves in the proportion of 1 to 300 in water (distilled- and well-water), with a light yellow colour. For the detection of zinc, the extract dried at 110° C. is lightly charred, then finely powdered and boiled out with nitric acid. In the decoction zinc is easily determined in the usual way. If the extract was adulterated with alum, the latter can also be determined in the nitric acid solution.

The determination of extract of turmeric is based upon the property of this extract to dye wool directly without a mordant, which property the colouring matters of fustic do not possess. The wool fibre has not the property of being directly dyed by the colouring matters of fustic, but the animal fat adhering to it acts as a feeble mordant for these colouring matters. The latter must, therefore, be very carefully removed from the fibre before a tissue is used for a test of this kind. The most suitable material for such tests is well-scoured white woollen cashmere.

One gram. of the extract under examination is dissolved in 50 ccm. hot water, diluted to $\frac{1}{2}$ litre with cold distilled water, and poured into a porcelain dish. The cashmere is then entered, the liquid is brought to the boil in a quarter of an hour under constant stirring, and after boiling five minutes the piece is taken out and well washed. If then its colour is pure white, no trace of turmeric was contained in the extract under examination. If the colour of the tissue is yellow, then adulteration with turmeric or aniline dyestuffs has taken place. For a closer examination the cashmere is extracted with alcohol, and the latter evaporated to a few ccm. A part of it is used for testing for aniline dyestuffs possibly present; if there are none, only the adulteration with turmeric is possible. To be sure, however, in cases of adulteration with alum, in which case fustic would dye directly, the following tests are made:—

Reagent.	Turmeric.	Fustic.
Stannous chloride...	Reddish precipitate.	Light yellow precipitate.
Acetate of lead.....	Chestnut brown.	Reddish yellow.
Ferric sulphate	No precipitate; solution coloured brown.	Black precipitate; solution coloured brown, afterwards turning olive green.
Caustic alkalis.....	Brown colouration.	Dark orange colouration, but no precipitate.
Mineral acids	Red colouration; no precipitate; on diluting the colouration disappears, and the dyestuff separates out in yellow flakes.	A light yellow precipitate is formed.

More difficult than the determination of turmeric is the ascertaining of an adulteration with quercitron. There is absolutely no literature on this subject, and the author has not yet succeeded in discovering an accurate method, and resorts to dye trials.

Wool is not directly dyed by extract of quercitron, and alum is but a feeble mordant for quercitron upon wool. Quercitron produces with alum only a feeble colouring, whilst fustic gives a deep yellow colour. Tin, especially stannous chloride in presence of an acid, such as tartaric, oxalic, or hydrochloric acid, dyes in combination with quercitron a deep orange upon wool, while fustic gives delicate shades.

The difference in the behaviour of quercitron and fustic extracts towards alum and tin salt affords us some points for the possible detection of quercitron in extract of fustic. A piece of white woollen cashmere, 10 cm. by 20 cm. dyed in a mixture of 0.5 gram. of extract, 0.2 gram. of alum, 0.5 gram. of stannous chloride, 0.5 gram. of oxalic acid in 1 litre of water, if

compared with a pattern dyed with an extract adulterated with quercitron will show different results, which difference manifests itself by the greater intensity of colour of the adulterated extract. If now a swatch of the same size be dyed in the extracts under comparison, but with alum mordant alone, the adulterated extract will give weaker colourings than the pure extract of fustic. With some practice in comparative dye trials even the percentage can be determined with approximate certainty. Although this method does not yield quantitative results, it is sufficiently accurate for many cases occurring in practice.

A determination of quercitron as to its containing tannic acid and of different properties of the extract is not practicable, as there are two colouring matters contained in extract of fustic, one of which, the morin, as the investigations of Hlasiwetz and Pfannmüller, &c., prove, behaves analogous to quercitron. Hlasiwetz states, and proves, that quercitron contains the elements of morin and quercetic acid, and thereby explains the analogy of the behaviour of morin and quercetin:—

The other colouring matter contained is extract of fustic, moritannic acid, or machurin, has the decided character of a tannic acid. With the extracts of fustic, therefore, all reactions peculiar to tannic acids can be obtained.

The determination of saccharine admixtures, as molasses, syrup, dextrin, is carried out in an analogous manner as stated, when dealing with logwood extracts, that is, by extracting the products with absolute alcohol, and determining the sugar or dextrin in the residue.

As with logwood extracts, the practice of excessive adulteration is carried on with extracts of fustic. Prime qualities are mostly already mixtures containing for every 100 parts of extract of fustic 15 parts of admixture (15 per cent.). With second qualities 30 per cent. is reached. As an illustration, the following method of manufacture will serve to show what takes place in practice,

For the production of fustic extract pure fustic is not employed, but a mixture of about 95 per cent. of fustic and 5 per cent. of quercitron bark. Since the best fustic, as will shortly be seen, yields at the most only 15 per cent. of solid extract, while quercitron bark often gives 30 per cent. of solid extract, it follows that most extracts of fustic which are offered in the market as pure, contain already from the start 10 per cent. of admixture.—W. S.

The Composite Indophenol-Indigo Vat. E. Noeltling. Chem. Zeit. 13, 725.

In reply to the criticism of Kertész (see this Journal, 1889, 539), the author states that his experiments, on the basis of which he made the assertion that an economy of 25 per cent. was realised with the composite vat as against the pure indigo vat, were made at the works of Koechlin, Baumgartner, and Co., and that H. Koechlin, the manager of the works, confirms his statement. Koechlin is of opinion that the vats used by Kertész were probably too alkaline, and excess of alkali prevents the fibre from absorbing either indophenol or indigo. Koechlin and Galland have lowered the cost of reduction of the composite vat by replacing the more expensive tin salt by zinc dust. With this improvement the concentrated vat is now prepared as follows:—10 kilos. of a good quality of indigo are mixed with 33 litres of warm water and allowed to stand 24 hours; then 2 litres of caustic soda of sp. gr. 1.348 are added, the mixture well agitated and placed in the grinding-mill along with 3 kilos. 300 grms. of indophenol. This mixture is ground for 12–24 hours and afterwards put into a barrel of a capacity of 500 litres; then 48 litres of sodium bisulphite of sp. gr. 1.374 are added and well mixed, after which 9 kilos. of zinc dust (containing at least 90 per cent. of zinc), which has been stirred with 10 litres of water, are gradually added, followed by 30 litres of caustic soda of sp. gr. 1.348, which are slowly mixed, and finally the barrel is filled up with water. The dye vat for dark shades is made by taking the contents of two such

concentrated vats and adding them to 4,000 litres of water, previously placed in the vat, along with a solution of sodium hydrosulphite, prepared by mixing together 12½ litres of sodium bisulphite of sp. gr. 1.374, 2 kilos. of zinc dust, 8 litres of caustic soda, and 25 litres of water.

Thirty pieces of cloth, each of 100 metres length, are usually dyed together. They are given three passages through the vat, being alternately immersed for three minutes and exposed to the air for four minutes. After the third passage they are chromed in a cold solution containing 2 grms. of bichromate of potash per litre, rinsed and dried. Each piece absorbs 950 grms. of indigo during the dyeing, and this amount must be replaced by adding to the vat 4 litres of the concentrated vat.

For paler shades of blue, only ½ or ¼ as much of the concentrated vat need be used.

With regard to the economy of the composite vat, whereas each piece of cloth requires 250 grms. of indigo and 83 grms. of indophenol for a full shade of colour, 400 grms. of indigo, used by itself, are required for the same shade. With indigo alone, the cost per piece amounts to 5.60s., whilst the cost with the composite vat is 4.33s., namely, 3.50s. for indigo and 0.83s. for indophenol. Adding to these sums the costs of reduction, as calculated by Kertész, namely, 0.48s. per kilo. of indigo with lime and zinc dust, and 1.10s. with sodium hydrosulphite, the relative costs will be 4.70s. per piece with the composite vat against 5.70s. with indigo alone. It is suggested that the cost of reduction in the case of the hydrosulphite vat, as given by Kertész, is too high, which is probably explained by the higher prices of zinc dust and bisulphite in Hungary.—E. B.

The Composite Indophenol-Indigo Vat. Report presented to the Industrial Society of Mulhouse by G. Galland. Meeting of May, 1889.

THE hydrosulphite vat of Schützenberger and de Lalande is found most suitable for the reduction of the mixture of indophenol and indigo. The method adopted by Koechlin, Baumgartner, and Co., of Loerrach, is then given, as reported in the preceding abstract.

After a vat has been in use some time it is advisable to ascertain its condition by a dye-test on the small scale, so that the amount of hydrosulphite necessary to replenish the vat may be added. This mode of setting the vat is more simple than any other, and possesses the advantage that the vat remains clear. The dyed blue can be discharged by the chromic acid method like ordinary indigo.

The presence of both indophenol and indigo in a sample of dyed cloth is easily shown on treatment with alcohol, which dissolves the indophenol, leaving the indigo on the fibre.—E. B.

PATENT.

An Improved Process and Apparatus for Cleansing Wool and other Textile Products. I. Singer and M. W. Judell, Adelaide, S. Australia. Eng. Pat. 2532, February 20, 1888. (Amended Specification.) 8d.

THE process consists in passing wool automatically and continuously through successive baths of bisulphide of carbon, whereby the grease is completely removed. A full description of the process and apparatus has already appeared in this Journal, 1889, 24–29. For the emendations the specification must be consulted. Six claims are withdrawn.—E. J. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Manufacture of Sodium Sulphide. J. V. Esop. Zeits. f. angew. Chem. 1889, 284—286.

SODIUM sulphide is generally made either by double decomposition or by reduction of sodium sulphate. The former process was described by W. Weldon (this Journal, 1882, 129—130). Another process of double decomposition is that of barium sulphide and sodium sulphate, but this process is only practicable where there is a ready sale for barium sulphate as "blanc fixe." As regards the reduction of sodium sulphate, this article is ground to a coarse powder, mixed with coal-dust in the proportion of 3 to 2, and the mixture heated in a reverberatory furnace. The furnace is 6 metres long, 2 metres wide, 1·7 metres high, and well lined with fire-brick. The bed is divided into two portions, that next to the fire-bridge for the reduction, and the other for the preliminary heating of the charge, which may consist of 150 kilos. of sodium sulphate and 100 kilos. of coal. About 1½ hours are required for the reduction of this charge. At the end of the operation the fluxed mass is run into iron boxes which are well closed, in order to prevent oxidation. Perhaps a revolving furnace may yet be employed for the reduction, although a few experiments in this direction gave unsatisfactory results. The mass obtained from the furnace weighs about 110 to 115 kilos., and contains up to 60 per cent. of sodium sulphide. Its appearance should be red and porous, but not grey and dense. The cooled mass is broken up into large balls, and thrown into lixiviating vats, arranged and fitted on the same principle as black-ash vats. The lixiviation is performed with warm water, and the liquor running from the strongest vat stands at 32° B. It is allowed to settle for an hour or so, and afterwards run into shallow iron crystallising pans, where, after four or five days, a copious crop of yellow or brown crystals is formed having the formula $\text{Na}_2\text{S} + 9\text{H}_2\text{O}$. The mother-liquor is siphoned off and again boiled down to 31° B. for further crystallisation. The large crystals formed are broken up, allowed to drain, and ultimately jigged in a centrifugal machine, whereby they obtain a lighter appearance. Dark crystals are washed with light concentrated liquor, which improves their appearance. The salts obtained during the concentration of the liquors, owing to their oxidation, are employed in the furnace in the place of sodium sulphate.—S. H.

Manufacture of Sodium Nitrite. J. V. Esop. Zeits. f. angew. Chem. 1889, 286—288.

SODIUM nitrite is one of the most important chemicals used in the manufacture of azo-dyes. There exist several methods for its manufacture, all of which are based on the reduction of sodium nitrate by means of lead. For this purpose the latter is fused and poured on iron plates in thin layers. After cooling, the lead plates are rolled up, and weighed out in parcels for use. The lead should be free from zinc and antimony. The sodium nitrate is then fused in shallow cast-iron pans fitted with a mechanical agitator, and when the mass is thoroughly fused, two and a half parts of lead are added at short intervals for each part of sodium nitrate (95—96 per cent. NaNO_3). The reduction ensues immediately. The thin leaves of lead fuse easily, and are oxidised to yellow lead oxide (litharge). After some time a further amount of lead is added, as an excess of lead is necessary, and the agitation of the fused mass is continued for at least three-quarters of an hour, in order to obtain a product of high strength. The mass has a tendency to stick to the sides, and great care must be exercised to remove these crusts with an iron spatula, as the slightest inattention causes the burning through of the pan. If the crusts turn reddish, it is a certain sign that the pan is in great danger of being destroyed. These crusts must at once be covered by a fresh quantity of nitrate, and the fire withdrawn if necessary. The whole process of fusion is finished in about 3½ hours. A sample drawn should test at least 90 per cent. of sodium nitrite. The mass after cooling is lixiviated in wrought-iron tanks with water or weak liquor. As soon as

the solution stands at 36 to 38° B. it is siphoned off and neutralised with nitric acid of 1·029 specific gravity. The liquor is then concentrated to 12 or 13° B., allowed to clarify for three or four hours, and ultimately run into lead-lined wooden tanks. Crystals of a light yellow colour quickly make their appearance, which are deprived of their adherent moisture in the customary manner. The mother-liquor, in conjunction with other liquors, is again boiled down to crystallisation. In this way crystals are obtained of the following percentage:—

	NaNO_2
	Per Cent.
1st crystallisation.....	95·9 to 95·5
2nd "	94·8 to 95·0
3rd "	94·2 to 94·5
4th "	94·0 to 94·2

By drying at 60° C. their percentage is increased to 96 per cent. If a purer product be required, it must be re-crystallised. Some difficulty is experienced in working up the mother-liquors. If crystals of only 94 per cent. of NaNO_2 , or below that strength, be obtained, the mother-liquors must be concentrated by themselves in pan No. 2. Here crystals, containing 86 to 92 per cent. of NaNO_2 , are produced, which are employed for enriching the strength of fresh liquors. If the crystals from pan No. 2 sink below 80 per cent., their mother-liquors must be concentrated separately in pan No. 3, whereby crystals containing 50 to 75 per cent. of NaNO_2 are obtained. These serve for enriching the liquors in pan No. 2. Weaker crystals are returned to the melting pot and treated with lead. Nevertheless, it is sometimes difficult to avoid the formation of salts, which require a special treatment in every case, as, for instance, the following tests show:—

	I.	II.	III.
NaOH	16·89	11·84	10·32
Na_2CO_3	22·00	17·66	15·17
NaNO_2	20·52	22·09	21·25
NaNO_3	16·23	19·07	20·36
NaCl	6·05	8·24	8·78
Na_2SO_4	17·39	15·54	16·02
Insoluble.....	7·23	6·96	7·05

The lead oxide, obtained as a by-product, is washed, and afterwards converted into the different lead preparations of commerce, or reduced to metallic lead, when it returns to the process.—S. H.

Action of Acids on the Thiosulphates. Berthelot. Compt. Rend. 108, 971—978. (Compare this Journal, 1889, 541.)

DILUTE solutions of boric acid and sodium thiosulphate remain mixed without decomposition, even after several days; hence, the heat of neutralisation of thiosulphuric acid is probably greater than the heat of formation of borax, viz., 11·6 cal. Acetic acid (30 grms. per litre) has no immediate action on the thiosulphate. A very slight decomposition sets in after a few minutes, rendering the liquid opalescent; but even after several days it makes little progress. Dilute sulphuric acid and sodium thiosulphate, both one-eighth normal strength, mixed in equivalent proportions at 11° C., disengage at the moment of mixture + 0·1 cal., the liquid remaining clear. Almost immediately afterwards the solution becomes turbid, with precipitation of sulphur and an absorption of heat of - 0·2 cal. Dilute hydrochloric acid added to excess of sodium thiosulphate also produces a momentary and very slight disengagement of heat ($\text{Na}_2\text{S}_2\text{O}_3 + \frac{1}{2}\text{HCl}$ disengages + 0·01 cal. at 11·5° during the first seconds). This is followed by a progressive absorption of heat and deposition of sulphur. With stronger hydrochloric acid, or a larger proportion, or at a higher temperature, the latter change is more rapid, and is

the only one observed. The author considers the heat of neutralisation to be about + 13.8 cal., that is, very near to hydrochloric and hyposulphuric acids. The total absorption of heat observed in these experiments, viz., - 1.0 to - 1.3 cal., corresponds to the difference between the heat of formation of sulphurous and thiosulphuric acids from their elements, i.e., $38.4 - 39.7 = - 1.3$ cal. The decomposition of the liberated thiosulphuric acid into sulphurous acid and free sulphur takes some hours for completion, and is complicated by the union of some of the thiosulphuric acid with some of the sulphurous acid to form thionic acids. The addition of sulphurous acid to sodium thiosulphate solution causes an evolution of heat, but sulphur is soon deposited, especially when the thiosulphate is in excess. The quantity of iodine decolorised by the mixture decreases progressively for several days. The combination of the two acids is never complete, since the thionic acids formed are all liable to slow decomposition, producing sulphurous acid, sulphur, and other thionic acids.—J. M. H. M.

Action of Air on Manganese Carbonate. A. Gorgen. Compt. Rend. **108**, 1006—1009. (Compare this Journal, 1889, 541.)

At the ordinary temperature carbonate of manganese, whether native, precipitated, or crystallised from solution in carbonic acid water, is oxidised with difficulty whether exposed to air or to aerated water. In the most favourable case—the precipitated carbonate kept for 10 years in aerated water—the proportion of oxygen combined was only that required to form $\text{MnO}_2 \cdot \text{MnO}$. The same compound, produced by directly combining an equivalent of hydrated manganese dioxide with one of hydrated manganese monoxide, does not absorb any additional oxygen, even after five months' exposure to air or water. Manganite, $\text{MnO}_2 \cdot \text{MnO}$, is then the limit of oxidation at the ordinary temperature. At 100° , however, and still more at 200° , the carbonate, the protoxide, and the sesquioxide readily undergo oxidation beyond this point, and may be perhaps completely converted into dioxide. The author concludes, in the absence of any analyses showing the native dioxide of manganese to have been produced from the carbonate, that such has not been the case.—J. M. H. M.

Formation of Nitre Deposits. A. Muntz and V. Marciano. Compt. Rend. **108**, 900—902.

See under XV., page 627.

The Salt Deposits of Cheshire. T. Ward. Transactions of the Surveyors' Institution, **21**, 429.

This paper deals specially with the changes made on the surface of the land, by the getting of the underlying salt, and with the nature of the damage to land and buildings caused by subsidence. The rock salt of Cheshire consists of a varying mixture of marls and salt, commercial rock salt of the best class containing about 95 per cent. of salt and 5 per cent. of marl. The Cheshire beds were formed in triassic times, from the evaporation of a series of salt lakes, and form two very thick deposits and a number of thin ones. The lower bed is worked by mining only, and the rock salt is sold chiefly for agricultural purposes. The upper bed was formerly worked by mining, but now exclusively by pumping the brine, all the mines previously in existence in the upper bed having been destroyed by flooding with water or by collapse of the roof. Brine originates by the natural infiltration of water through the strata until the bed of rock salt is reached, when a process of solution takes place, until the brine contains 26 per cent. of salt, and is saturated. This process is continually going on, for the pumping causes a constant flow of brine along the top of the rock-salt bed, the supply being maintained by water entering at the margin of the bed, and becoming saturated in its course over the rock salt to the pumping centre. The action of the fresh water is thus to dissolve away the upper surface of the rock-salt bed, and the space previously occupied by the dissolved salt is filled up by subsidence of the overlying earth. The effect is seen at the surface in

depressions of the ground, which are continually causing great damage to property. The normal form of a subsidence caused by brine pumping is that of a trough, as shown on Fig. C'. Figs. A and B show the relative positions of the strata in two places near Northwich. White salt is obtained by evaporation of the brine in shallow iron pans, the various grades of salt being produced by variations in the rate of evaporation. Fine-grained salt for domestic use requires rapid boiling, whilst a coarser grained article is obtained by conducting the evaporation at a lower temperature.—G. H. B.

PATENT.

Improvements in the Manufacture of Cement and the Utilisation of the Lime-mud Residue of the Ammonia-Soda Process therefor. J. S. Rigby, Liverpool. Eng. Pat. 3148, March 1, 1888. 4d.

THE inventor washes out the alkaline earthy chlorides as far as possible with hot water, and then adds sodium silicate in sufficient quantity to convert the remaining alkaline earthy chlorides into insoluble alkaline earthy silicates. Finely-divided clay is then added in the required proportion, and the mixture is calcined, ground, and "purged" as usual.

—E. G. C.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

On the Opaque-Etching of Glass. A. Lainer. Dingl. Polyt. J. **272**, 237—239.

THE following two recipes obviate the use of expensive fluorine salts usually employed in the preparation of solutions for the opaque-etching of glass.

(a.) 10 grms. of soda are dissolved in 20 grms. of warm water, and 10 grms. of potassium carbonate in 20 grms. of warm water; the solutions are mixed and 20 grms. of concentrated hydrofluoric acid are added, and 10 grms. of potassium sulphate dissolved in 10 grms. of water also added to the mixture. The addition of a small quantity of hydrochloric acid gives a fine granulation to the etched surface.

(b.) 4 cc. of water, $1\frac{1}{2}$ grms. of pure potassium carbonate, 0.5 cc. of (dilute) hydrofluoric acid, 0.5 cc. of hydrochloric acid, and 0.5 cc. of potassium sulphate are mixed, and the mixture treated with concentrated hydrofluoric acid and potassium carbonate, until the mixture produces the requisite degree of opacity.

Kampmann, of Vienna, uses a simpler method than either of the above two for preparing an opaque-etching fluid. A wooden vessel bound with asphalted metallic hoops is filled up to about one-fifth of its volume with highly concentrated hydrofluoric acid, and this is partially neutralised by the gradual addition of crystallised soda. After the first few quantities the soda should be added in a "polarised" condition, whilst the whole is stirred up with a wooden or a glass rod. When the white frothy mixture is sufficiently thick to remain adhering to the rod, neutralisation should cease and the mixture possess a strongly acid reaction. The process should be carried on in the open air, as large quantities of carbonic and hydrofluoric acids escape. The mixture of sodium fluoride and hydrofluoric acid is transferred to a large tub and diluted with 5—10 volumes of water, according to the concentration of the acid used. The efficiency of the mixture is next tested by etching glass with it for two hours. If it be too strong, the surface of the glass is rough, irregular, and seemingly covered with crystals; if too weak, the etching is uniform, but translucent. To the strong mixture, water is added, to the weak, more concentrated hydrofluoric acid, treated with soda, is added. By the latter means spent solutions may be revived. The following is a convenient method of preparing a small quantity of etching liquid. 240 cc. of commercial hydrofluoric acid

A ROCK SALT MINE NORTHWICH

(sp. gr. 1.2583) are treated with 600 grms. of powdered crystallised soda and diluted with 1,000 cc. of water. About 1,600 cc. of the mixture are obtained. (The specific gravity of the acid is determined in a flask which holds about 260 cc., and which is lined with wax.) On standing for some time a sediment settles with a clear supernatant liquid. Before etching, the glass must be thoroughly cleaned and then provided with a rim of wax (yellow wax, tallow, colophony, and asphalt powder, &c. kneaded together) and etched for a few minutes with ordinary hydrofluoric acid (1:10) solution. This is poured off into a separate india-rubber flask and the glass washed with water and wiped almost dry with a soft sponge. The etching liquid is then stirred up and poured on to the glass, $\frac{1}{2}$ to 1 cm. thick. In an hour's time a fine opaque etching is obtained. The liquid is poured off and the plate washed with water, and water is allowed to stand on it till a thin film (silicates) forms on the glass. This is rubbed off with the finger or a brush, and the glass is finally washed with water. By subsequent treatment with hydrofluoric acid the opaque-etching can be brought down to any degree of transparency. If the etching liquid be not stirred up and the supernatant clear liquid used, a good etching is produced in two hours' time, but the solution loses its strength rapidly if used repeatedly. The thick paste alone, without the supernatant liquid, produces a good etching in an hour's time. If the mixture be only allowed to act for half an hour a thin etching is not obtained but one the grain of which is very open.—F. W. T. K.

PATENTS.

Improvements in Muffle Kilns for Bending and Firing Stained Glass, Tiles, Pottery Ware, and for other suitable Purposes. G. Lazenby, Leeds. Eng. Pat. 6980, May 10, 1888. 8d.

THE muffle kiln is constructed in such a manner that it is equally heated on its sides and at its top and bottom, while its interior is free from the products of combustion, which cannot possibly come in contact with the articles being fired or burnt.—E. G. C.

An Improvement in the Manufacture of Glass. J. T. H. Richardson, Hatton. Eng. Pat. 7309, May 17, 1888. 4d.

FLINT or other glass is hardened during the process of manufacture by an induced current or currents of cold air or gas, or by sudden immersion into a refrigerated air or gas chamber.—E. G. C.

Improvements in the Art of Enamelling or Decorating Slate, Marble, and such like Materials. W. J. Temple, F. W. Rogers, C. W. Trotman, and T. F. Hobbs, Bristol. Eng. Pat. 12,596, September 1, 1888. 4d.

THE material to be operated on is coated with any suitable metallic surface upon which the decorations are made.—E. E. B.

An Improved Composition for Manufacturing Crucibles or the like Vessels or Utensils. E. J. T. Digby, London. Eng. Pat. 17,521, December 1, 1888. 4d.

THE improvement consists in using a composition for the manufacture of crucibles at less cost and having greater fire-resisting properties than heretofore. The component parts are Herin Island granite, plumbago and Welsh slate in equal proportions, with German clay equal to one-fourth of the entire mass. These are ground separately into a fine powder, and having been passed through a dressing machine are mixed together into a thick paste with water, and moulded into the desired shape. After drying in a cool chamber for 24 hours they are thoroughly baked in an oven.—E. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Solubility of Minerals in Sea Water. J. Thoulet, Compt. Rend. 108, 753—755.

THE solubility of obsidian, pumice, amphibole, orthoclase, marble, sea shells, and coral in sea water is extremely small; very much less than in distilled water.—J. M. H. M.

PATENTS.

Improvements in the Manufacture of Portland or similar Cement. J. Robertson and J. A. Patrick, Glasgow. Eng. Pat. 2632, February 22, 1888. 4d.

THE inventors employ a mixture of crushed limestone and poor shale, or "blaes."—E. G. C.

Improvements in certain Fire-resisting Materials. J. M. and D. D. Spence, Manchester. Eng. Pat. 4617, March 26, 1888. 8d.

THIS invention "consists, firstly, in a method of forming a mixture of alum and a suitable anti-tumefaction material, such as sawdust, into solid compact cakes, which occupy a greatly reduced space; and, secondly, in the use of the cakes so formed for filling the hollow jackets of fire-resisting safes, boxes, chests, and chambers, and the cavities of fire-resisting doors, and also in the interiors of fire-resisting floors."—E. G. C.

An Improved Plastic Composition for Moulding and other Purposes. F. Beer, Paris, France. Eng. Pat. 5253, April 9, 1888. 6d.

THE ingredients used are pulverised marble, pulverised glass, pulverised quicklime, and silicate of soda or potash.—E. G. C.

Improvements in Cement, in "Cooling" or Maturing the same, and in Apparatus therefor. A. M'Ar, Glasgow. Eng. Pat. 5881, April 20, 1888. 8d.

THE cement is "air-slaked" by a blast or current of air, and the addition of 10 per cent. of carbonate of lime is found to be advantageous by the inventor.—E. G. C.

Improvements in and relating to Cement. J. C. Sellars, Birkenhead. Eng. Pat. 6261, April 27, 1888. 6d.

THIS invention relates to the production of a cement which shall be applicable for use in the building of all kinds of erections (such as retort benches, ovens, gas producers, &c.) subject to heat. An alkaline composition of "fluvial, plastic nature" is admixed with Sellars' or other cement as a base.—E. G. C.

Improved Means for Testing or Measuring the Strength of Cement and other Materials. H. Buignet, Havre, France. Eng. Pat. 6690, May 4, 1888. 8d.

THE block of cement or other material is connected by a lever to a buoyant plunger or float, supported by a fluid (preferably mercury) contained in a stationary vessel communicating at its lower part with a vessel charged with the same liquid and capable of vertical adjustment. "By raising the adjustable vessel, the upward pressure of the liquid on the float and the strain exerted by the float on the materials can be gradually increased, the amount of force thus exerted being indicated with great precision by a graduated tube showing the height of the liquid in the stationary vessel."—E. G. C.

An Improvement in Bricks and Building Blocks. H. G. Carew and F. B. Potts, London. Eng. Pat. 7327, May 17, 1888. 4d.

Cavities in the bricks, which may be made of any of the ordinary materials, are filled with charcoal in the form of cubes, squares, &c., to absorb noxious gases, and the charcoal can be readily changed when necessary.—E. G. C.

An Improvement in Fire-Proof Columns. R. Mannesmann, Bleidingshausen, Germany. Eng. Pat. 8485, June 9, 1888. 6d.

Each column consists of two tubes, preferably of steel, one within the other. The annular space between the two tubes is packed with asbestos, or some other incombustible and badly-conducting material.—E. G. C.

Improvements in the Manufacture of Cement from the Calcium Sulphide Waste of Leblanc Soda Manufactures. J. S. Rigby and A. McDonald, Liverpool. Eng. Pat. 9763, July 5, 1888. 6d.

The greater part of the sulphur is first expelled from alkali waste by carbonic acid, and the remaining sulphur and sulphur salts are mixed with clay or its equivalent, the mixture then being calcined, ground, and "purged."—E. G. C.

Improvements in the Continuous and Economical Manufacture of Cement. F. W. S. Stokes, London. Eng. Pat. 9986, July 10, 1888. 1s. 1d.

This specification contains a detailed description of the apparatus adopted by the inventor in the production of finished cement from the raw materials by the "semi-dry" process, and references are made to past patents (7888 of 1886, 9694 of 1887, and 10,764 of 1887).—E. G. C.

Improved Manufacture of Cement suitable as Plaster and for Moulding Purposes. G. H. Sharpe, London, and F. W. Turner, Carnarvon. Eng. Pat. 19,010, December 29, 1888. 4d.

The materials used are slate dust (66 per cent.), quicklime (30 per cent.), and limestone (4 per cent.), dried and burned separately, mixed, and comminuted.—E. G. C.

A New Combination of Materials forming a Cement for Cutlery. W. T. Wheatley, Sheffield. Eng. Pat. 1206, January 23, 1889. 4d.

The ingredients are roll sulphur (80 per cent.), purified anhydrous calcium sulphate (16 per cent.), zinc oxide (3 per cent.), and, sometimes, alumina silicate (1 per cent.).—E. G. C.

Improvements in Artificial Building Materials. J. Sugden, London. Eng. Pat. 2632, February 14, 1889. 4d.

The materials used are sawdust, calcined magnesia, plaster of Paris, chloride of magnesium, and coarse jute.—E. G. C.

Improvements in the Manufacture of Artificial Stone. A. C. Ponton, Parkstone, B. L. Mosely and C. Chambers, Hastings. Eng. Pat. 2844, February 18, 1889. 4d.

These inventors claim (1) "a liquid siliceous cement composed of a siliceous hydrogel and an alkaline silicate made in the manner and in the proportions herein named, for binding together pulverulent, granular, or coarse material; . . . (2) the combination of the cement described with carbonate of lime; (3) combination of the cement with powdered whiting and sand," &c., &c.—E. G. C.

Improvements in the Manufacture of Elastic Tiles. Sir E. J. Harkand, Bart., Belfast. Eng. Pat. 4806, March 19, 1889. 4d.

The tiles are made of vulcanised india-rubber, and are fixed to the floor or other surface to be covered by a cement composed of two parts of gutta-percha, one part of resin, and one part of Stockholm tar.—E. G. C.

Improvements in and relating to the Treatment of Slag for a variety of Important Uses, such as making it Cellular for Pavements, Walls, and the like. St. G. T. C. Bryan, Birmingham, Alabama, U.S.A. Eng. Pat. 5190, March 26, 1889. 6d.

The slag is rotated while molten, to separate impurities, after which carbonic acid and hydrogen gases are forced through the liquid mass. Building blocks of slag, "in part solid and in part cellular," are then produced in a manner described at length in the specification.—E. G. C.

An Improved Plastic Fire- and Weather-Proof Wood Mass. J. G. Wolf, Graz, Austria. Eng. Pat. 6348, April 13, 1889. 4d.

The material, termed "Ossalith," consists of a mixture of sawdust, shavings, wood pulp, and similar substances, with calcined magnesite and chloride of magnesium, and can be made harder or softer by varying the proportion of the materials. The calcined magnesite is made into a thin cream with the chloride of magnesium and the reduced wood stirred into until a stiff pasty mass is produced, which is then dried.—E. E. B.

A New or Improved Continuous Lime and Cement Kiln or Furnace. A. Schlofer, Laegetdorf, Prussia. Eng. Pat. 8012, May 14, 1889. 6d.

The kiln is as usual vertical, and the body of the furnace is dome-shaped and much wider than the vertical shaft which enters the middle of the dome. The furnace is supplied continuously with chalk or cement through an opening in the shaft a short distance above its junction with the body of the furnace, and is kept filled up to the level of the opening. As the shaft is narrower than the furnace, and the top of the body of the latter dome-shaped, the chalk or cement fed through the shaft leaves an empty space round the top of the dome which has to be filled by means of openings communicating with the outside of the furnace. Drawings of the kiln accompany the specification.—E. E. B.

X.—METALLURGY.

Reduction of Silica and Boric Anhydride by Magnesium. N. J. Tram. Chem. Zeit. 13, 680.

The products of the action of magnesium on silica, boric anhydride, and metallic oxides are always alloys of magnesium with the other metal or metalloïd and separation of the two is only effected with great difficulty. Molybdic anhydride is reduced by magnesium with incandescence and violent detonation, the product being an alloy of molybdenum and magnesium.—C. H. B.

Preparation and Properties of Metallic Manganese. C. Ballock. J. Franklin Inst. 98, 62—64.

MANGANESE is generally stated to be so easily oxidised as to require keeping under rock oil; it is said to decompose water, evolving hydrogen.

Cast manganese containing 8 per cent. of iron is said to be unalterable in air.

If instead of the usual method of obtaining it (viz., by the reduction of its oxide by carbon) Brunner's method be employed, the product is found to be no more easily

oxidisable than iron. The process was carried out by mixing pure fused powdered manganous chloride with an equal weight of powdered fluorspar; ounce charges of this mixture were placed in a French clay crucible, heated to redness, 80 grains of sodium in small pieces added, and the crucible covered until the reaction had ceased, when it was ready for a fresh portion. By this means buttons of metal were obtained weighing about 20 per cent. of the chloride used.

A higher temperature than is necessary should be avoided or the crucibles will be badly attacked. Manganese got by this process is very brittle with a steel-white fracture, scarcely touched by a file, not readily oxidisable, quite unattracted by a magnet; sp. gr. 7.072 becoming 7.153 when re-fused under sodium chloride.

On substituting sodium chloride for fluorspar as a flux, the yield was smaller, the metal less brittle, with a different fracture, and having a specific gravity of 7.231. When fluorspar was used the metal was contaminated with calcium, though free from iron. This may account for its higher specific gravity when re-fused under sodium chloride, and also when made without the use of fluorspar, seeing how low the specific gravity (1.57) of calcium is.—B. B.

Sulphurous and Desulphurised Blast-furnace Slag.

A. D. Elbers. Eng. and Min. Jour. 1889, 522 and 569.

BLAST-FURNACE slag usually contains sulphur as calcium sulphide, derived from both fuel and ore; the presence of the sulphide causes the slag to pass through two stages during solidification, the silicates first solidifying, and afterwards the calcium sulphide. In consequence of this irregularity, castings made of it are apt to warp and be unround.

Slag free from sulphur behaves as a homogeneous mixture of silicates, and passes through a viscous stage during cooling, which persists the longer the greater the difference between the solidifying points of its component simple silicates.

For the desulphurisation of the slag sodium nitrate can be used in the manner suggested by Heaton and Hargreaves, 20 years ago, for the purification and partial decarbonisation of pig iron, though less will be needed, as no carbon (with its low atomic weight and high valency) has to be oxidised.

Assuming the reaction $10\text{CaS} + 12\text{NaNO}_3 = 10\text{CaO} + 6\text{Na}_2\text{O} + 10\text{SO}_2 + 6\text{N}_2$ to occur, each single per cent. of CaS will require rather less than 1.5 per cent. of NaNO_3 , so that a charge of 2,000 lb. of slag containing 2 per cent. of calcium sulphide will need to be treated with about 60 lb. of sodium nitrate. The free basic substances, which, according to the above equation, are produced, serve to increase the duration of the fluidity of the slag, provided it be not already too basic, a condition obtaining if its oxygen ratio fall below that characteristic of a mono-silicate constitution. Besides sodium nitrate, the chloride may be used to get rid of iron by volatilisations as chloride. In addition to the direct benefits attained by the desulphurisation of slag, mentioned above, the following advantages accrue: The solidifying point is lowered, and the range of temperature during which the slag remains plastic is increased; moreover, that part of the slag which clings to the walls of the converter after pouring, can be scraped out before it sets, re-heated and moulded into suitable shapes. So marked is the convenience of this greater fluidity that it is recommended to add some cheap form of alkali (e.g. sodium carbonate) to such slags as require but little sodium nitrate for their complete desulphurisation. In this case the substance selected should be run in already fused, so as not to chill the charge, and cause it to solidify before it can all be used. Manufacturers are likely to comply with this condition, because every pound of the product wasted represents to them a fraction of a pound of material they have *bought directly*, and they are more apt to be alive to the need for economy with respect to it than to anything they have paid for *indirectly*, such as the untreated slag itself.—B. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

PATENTS.

Improvements in and connected with Secondary Batteries or Electrical Accumulators. L. Bristol, Bromley. Eng. Pat. 9854, July 6, 1888. *Sd.*

To increase the cohesiveness and rigidity of the plates and to do away with the necessity for a metallic support, the active material is mixed with hair or fibrous substances. A conductor of lead or platinum, having lateral branches, is inserted, and the whole subjected to a gentle pressure and dried. These plates are then placed inside bottomless cases having supporting strips of wood, and the necessary number of such cases placed inside a large water-tight case to form one cell. A simple form of gas escape plug is provided.—B. T.

Improved Connection for the Carbon or Agglomerate Plates of Galvanic Batteries. L. I. Dopping-Hepenstal, Granard. Eng. Pat. 10,627, July 23, 1888. *Ad.*

A piece of platinum wire or bar of suitable size is bent back upon itself and wedged into a hole or slit in the plate or block, the wedge action serving to give close contact.—B. T.

Improvements in or relating to Pyrometers. W. H. Grindley, Tunstall, and W. S. Hensley, Cardiff. Eng. Pat. 13,005, September 8, 1888. *11d.*

Coils of platinum or iridium wire are wound upon an insulating material such as porcelain, and introduced into the chamber whose temperature is to be measured; the terminations of these wires are brought to a suitable switch-board in connexion with a Wheatstone bridge of somewhat novel construction, enabling the resistance of the coils inside the chamber to be measured at any time. As the resistance of the wire varies with the temperature, it is possible by measuring its resistance to ascertain its temperature at that particular time.—B. T.

Improvements in Galvanic Batteries and in Electrolytic Baths. J. L. Roberts and H. L. Breyer, Brooklyn, New York, U.S.A. Eng. Pat. 18,194, December 18, 1888. *Sd.*

In order to prevent the diffusion of liquids in a two-fluid battery, a non-porous partition, but with electrolytic properties, is employed, and may be made of starch "boiled in a strong brine of some salt of an alkali, such as chloride of sodium or a salt of zinc," the gelatinous mass so produced being confined between walls of cloth to form the diaphragm of the battery. Other methods of forming similar diaphragms are described. Or, a porous cell may be soaked in an aqueous solution of silicate of soda or potash, and then dipped into muriatic acid or a solution of a salt such as chloride of iron. In this way silica is deposited in a gelatinous mass in the pores of the pot.—B. T.

An Improvement in Materials to be used in Galvanic Batteries. A. Cornwell, Melbourne, Victoria. Eng. Pat. 19,061, December 31, 1888. *6d.*

This is an improved method of preparing the saline matter referred to in Eng. Pat. 12,378 of 1885 (this Journal, 1886, 500), and is carried out thus:—Three fluid ounces of sulphuric acid are boiled with three fluid drachms of mercury until the latter is dissolved and the excess of acid evaporated. This mercuric sulphate is then dissolved in 10 oz. of water, and 2 oz. of common salt are added until a whitish colour at the required density (viz. 1.425) is obtained.—B. T.

A New or Improved Ozone-Producing Apparatus. H. A. B. H. de Vars, Paris, France. Eng. Pat. 5230, March 27, 1889. 6d.

A GLASS bell-jar, having its outer surface coated with tin foil, is inverted and placed over a glass cylinder having its inside coated with tin foil, the whole being covered with a large inverted glass bell. The outside tin foil is connected with the positive pole of an induction coil, and the inside with the negative. The apparatus is so constructed that a current of air can be passed up the centre cylinder and down between the outside of the cylinder and the inside of the coated bell-jar; at the same time the induction coil is set working and the moving air becomes electrified and changed into ozone. A vessel is arranged beneath for collecting the ozone.—B. T.

Improvements in Secondary Batteries. P. A. Newton, London. From W. Main, Brooklyn, New York, U.S.A. Eng. Pat. 6112, April 9, 1889. 8d.

THIS consists chiefly of an improvement upon the Merséle battery (Eng. Pat. 4311 of 1887; this Journal, 1887, 833), in the new battery the plates being placed horizontal, with the hydrogen plate below the oxygen plate. Vertical end plates of insulating material are placed in the cell, and rods of hard rubber or similar material are stretched across from end-plate to end-plate to support the active material, any desired number of layers of this active material being used. The hydrogen plate consists of a perforated copper tray carrying an amalgam of zinc and mercury, the oxygen plate of lead coated with carbon or a carbonised material to add to its conductivity. The electrolyte may consist of a solution containing zinc and mercury, or a dilute acid solution may be employed.—B. T.

Improvements in Thermo-electric Batteries. J. J. Shedlock and R. Mestern, London. Eng. Pat. 6119, April 9, 1889. 8d.

THE battery is so constructed that the electro-positive metal or alloy can be kept in a molten state by means of the combustion of coal or oil, while the metallic strips connecting these alloys are kept cool outside the molten metal by means of a current of air circulating round them. Any suitable number of these elements can be arranged round a circular combustion flue.—B. T.

Improvements in Secondary Batteries. G. E. Heyl, Charlottenberg, Prussia. Eng. Pat. 6865, April 24, 1889. 4d.

IN this battery the plates are made of a lead felt prepared by hanging up vertically thin round wires or threads of lead and allowing compressed air to blow upon them until they are thoroughly entangled. The felt is then compressed into plates of the required size, and molten lead poured round to form a framework. Plates thus formed have great porosity, and are not liable to short circuit.—B. T.

Improvements in Electric Secondary or Storage Batteries. T. H. Hicks, Detroit, U.S.A. Eng. Pat. 7002, April 26, 1889. 6d.

THE lead plates forming the elements are cast with shelves upon each face, the shelves being bent up so as to form retaining troughs to hold the active material. Oxide of lead is used upon one side of the plate and peroxide on the other. The requisite number of these plates are then fitted to serve as division plates between water-tight cells, one side being used as a positive and the other as a negative plate.—B. T.

CORRECTION.

It is requested that in the July issue, page 551, second column, line 5 of first abstract, the sentence, "The anodes and cathodes are of pure zinc," be corrected to read, "The cathodes are of pure zinc."

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Decomposition of the Neutral Fats by Heating under Pressure. C. Engler and S. Seidner. Dingl. Polyt. J. 271, 515—526 and 572—576.

See under H., page 607.

PATENTS.

Improvements in the Purification of Oils and Fats, and the Obtainment of Useful Products therefrom. W. A. Mitchell and O. C. Hagemann, London. Partly from M. Von Schmidt, Vienna, Austria. Eng. Pat. 6949, May 9, 1888. 6d.

IN carrying out this invention the fats or oils are placed in a vessel provided with stirrers and heated to 180° F. Soda crystals are then added and the whole mass well stirred. Instead of soda crystals other forms of carbonate of soda may be employed, but in such cases the amount of water used must not exceed 160 per cent. of the total amount of Na_2CO_3 added, otherwise an emulsion will be formed from which the oil or fat cannot be separated. After standing for some time, the mass separates into two layers of oil or fat and soap. The separated oil or fat is then washed or filtered and heated in a vessel into which carbonic acid or nitrogen is passed, by which means certain volatile impurities are removed. The carbonic acid or nitrogen can be re-used after purification by passing it through charcoal or solution of permanganate.—E. J. B.

An Improvement in the Manufacture of Soap. T. S. Steen, Londonderry. Eng. Pat. 9123, June 22, 1888. 4d.

THE inventor adds from 6 to 10 per cent. of a pure mineral oil of a specific gravity of about 0.875 to a "fitted" soap containing 70 per cent. of rosin. A sufficient excess of alkali must be added to saponify the mineral oil.—E. J. B.

Improvements in the Treatment or Purification of Fatty Acids and in the Apparatus employed therein. M. V. Brisset, Saint Denis, France. Eng. Pat. 10,296, July 16, 1888. 8d.

THE object of the invention is to remove liquid fatty acids from their mixture with solid fatty acids in a more efficient way than by pressure, which is the method at present employed. The process consists in dissolving the mixture in a suitable solvent, such for example as benzene, turpentine, petroleum ether, acetone, alcohol, carbon disulphide, &c. The solution is effected hot and on cooling the solid fatty acids crystallise out. The crystals are freed from the mother-liquor containing the liquid acids by means of a filter-press, centrifugal machine or vacuum apparatus. The whole of the operations are conducted in hermetically closed vessels.—E. J. B.

Improvements relating to the Preparation of Artificial Manures from Fish and other Substances and to the Extraction of Oil therefrom. C. Weigelt, Berlin, Germany. Eng. Pat. 11,505, August 9, 1888. 6d.

See under XV., page 631.

An Improved Composition for Use as Axle Grease or Stuffing Box Packing. G. Hervieux and V. Bédard, Québec, Canada. Eng. Pat. 4190, March 9, 1889. 4d.

THE inventors claim an axle grease consisting of 24 parts of cod-fish oil, 16 parts of beef tallow, 2 parts of soft soap and 1 part of rosin.—E. J. B.

An Improved Soap Powder. H. C. Foulsham, Broudesbury.
Eng. Pat. 4651, March 16, 1889. 6d.

THE improved soap powder consists of 20 lb. of soap, 12 lb. of alkali, 10 lb. of carbonate of soda, 70 lb. of soda crystals, and to each hundredweight of the mixture 3 lb. of paraffin and 2 lb. of turpentine are added.—E. J. B.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

PATENTS.

Improved Apparatus for Vulcanising Caoutchouc and Moulding Celluloid. J. Wirth, Paris, France. Eng. Pat. 9604, July 2, 1888. 8d.

THE inventor claims that by the use of his apparatus an economy both of time and steam may be effected. The specification is accompanied by 13 descriptive drawings.

—E. J. B.

Improvements in Plastic Compounds. P. M. Justice, London. From A. Gravelin, Liège, Belgium. Eng. Pat. 9665, July 3, 1888. 6d.

THIS invention relates to the manufacture of a substance called "Elurite," suitable as a substitute for ebonite, horn, &c. It is prepared in the following manner:—A mixture is made of 100 parts of paper pulp, containing about 50 per cent. of water, with 80 parts of blood. The mass is well kneaded, rapidly dried and powdered. 100 parts of this powder are mixed with 80 parts of blood, one part of powdered rosin, and $\frac{1}{2}$ part of linseed or other oil. If a pale-coloured product be desired, the serum of blood may be employed and to the mass may be added either casein, white of egg, gelatin, glue, starch, dextrin, or suitable gums. To increase the hardness a small percentage of silicate of soda may be added. The material may be moulded into

any desired form. It possesses greater hardness than wood, does not soften under heat, and is not rendered brittle by cold. It can be readily worked in a lathe, and being a non-conducting material can be used as an electrical insulator.

—E. J. B.

A Method of Producing a Useful Material or Materials from Greenstone, Diabase, and other Varieties of Hornblende. E. Murjahn, Hamburg, Germany. Eng. Pat. 4175, March 9, 1889. 4d.

THE minerals are dried, crushed, and treated with hydrochloric or sulphuric acid, the washed residue being applied to various uses, as paper making, manufacture of rubber compositions, &c.—E. G. C.

An Improved Solution for Rendering Cloth, Felt, Paper, and the like Waterproof. M. Gangl and I. Mossner, Vienna, Austria. Eng. Pat. 5763, April 4, 1889. 4d.

THREE solutions are prepared as follows:—(1.) One part of Indian isinglass is dissolved in 20 parts of hot water, and the solution neutralised with caustic soda; (2.) Ten parts of sugar of lead in 20 parts of hot water; (3.) 6·27 parts of alum in 150 parts of hot water. These solutions are mixed together, and the precipitate of lead sulphate is allowed to settle, and may be utilised as a paint. The solution is diluted with water and is then ready for use.

—E. J. B.

An Improved Buoyant Compound and Water-tight Covering or Enclosure therefor. A. M. Wood, Westminster. Eng. Pat. 7137, April 29, 1889. 4d.

THE inventor claims the manufacture of an "improved buoyant compound or material consisting of cork, rosin, and marine glue or bitumen with cocoa-nut husks, cane, bamboo chips, or whalebone, or with wax and shellac or gum kauri, or with woodite, rubber euphorbia or analogous gums." Also as a covering or cementing medium for pieces of buoyant material, "the improved cement consisting of rosin, pitch, and marine glue with kieselsuhr, asbestos, or whalebone powder or shreds."—E. J. B.

XV.—AGRICULTURE, MANURES, Etc.

Progressive Development of the Potato. A. Girard. Compt. Rend. 108, 602—604.

TWO hundred roots were planted at Joinville, and the investigation of their progressive development extended over about four months, the different portions of the plants being weighed, and analyses made, at six different periods. —E. G. C.

Fixation of Nitrogen by Arable Soil in Absence and in Presence of Vegetation. Berthelot. *Compt. Rend.* **108**, 700—708. (Compare this Journal 1887, 552; and 1888, 382.)

This paper is an abstract, by Berthelot himself, of a much longer one occupying over 200 pages of the *Annales de Chimie et de Physique* for April 1889, and the present abstract refers to both memoirs. In the latter journal the mode of experiment and the analytical processes are discussed in detail, and the figures relating to each separate experiment are set out. The experiments were made in 1888, and comprised 64 separate pots, following the lines of the author's previous experiments of 1883 and subsequent years. They establish, by the most rigorous figures, the increase in combined nitrogen of plain soil, under certain conditions, and next that the gain in nitrogen is much greater when certain leguminous plants are grown in the soil, and that in this case the gain in nitrogen takes place not only in the soil but also in both the underground and aboveground portions of the plant. As an example of the mode of experiment, the quantities dealt with, and the extent of the increase observed, experiment No. 53 may be cited, especially as it is one of those made under conditions which exclude any question as to the interference of atmospheric ammonia, nitrogen in rain water and nitrogen removed by drainage. On May 11th, 1888, a porcelain pot was filled with 2.145 kilos. of soil which had been carefully air-dried, stones, vegetable debris, and all foreign substances removed, rendered thoroughly homogeneous by very moderate crushing and sifting, and finally subjected to complete analysis. The quantity of soil named consisted of 1.950 kilos. of dry soil and 0.195 kilo. of water, and contained per kilo. of dry soil, 1.8998 grms. of combined nitrogen, 0.0122 grm. nitric nitrogen, and 19.8 grms. of organic carbon. As for the quality of the soil (the full analysis of which is given) it was a clay, rather poor in organic matter, and containing 5—6 per cent. of carbonate of lime. The pot was placed on a ground glass plate under a glass shade of about 45 litres capacity, and the joint rendered air-tight with vaselin. At the commencement of the experiment two determinations gave 0.9743 and 0.9743 of N per kilo. of dry soil. On July 3rd, 1888, after remaining undisturbed for seven weeks, two determinations gave 1.0610 and 1.0579, mean 1.0599 grms. of N per kilo. of dry soil. The total gain of combined nitrogen in the 1.950 kilos. dry soil is, therefore, 2.0629—1.8998 = 0.1631 grm., a quantity far exceeding the experimental error, which was carefully defined by trials in blank. This is exclusive of the nitric nitrogen, of which there was 0.0122 grm. present at the beginning, and 0.0391 grm. at the end of the experiment, so that a feeble nitrification had been in progress simultaneously. As a

control, a quantity of this soil was shaken for some time in a large flask kept filled with pure carbon dioxide, then transferred, without contact with air, to a smaller flask also filled with carbon dioxide, until the latter was full of soil. It was then corked, sealed, and laid aside for four months and a half; at the end of that time it gave 0.986 grm. of N per kilo. of dry soil, against 0.974 at the commencement, the difference being not greater than the experimental error. The gain of nitrogen in experiment No. 53 can, therefore, only be attributed to fixation of free atmospheric nitrogen by the soil under the conditions of the experiment, which are:—a porous condition of the soil, not absolutely pulverised, or injured by excessive crushing or rubbing, which may destroy microbes; gentle circulation of oxygen, giving rise to feeble but not very rapid nitrification, as a consequence of this, absence of reducing fermentations; presence of a limited quantity of water; temperature from 10°—40°; existence in the soil of a limited proportion of nitrogen contained in organic matter not undergoing putrefaction or any anaerobic fermentation; and finally, presence of the natural microbes of the soil. Precisely similar experiments made—(1) with the pots of soil under a glass shelter, but exposed to free circulation of air, and (2) with the pots fully exposed to air and rain, the drainage water being collected by a funnel and tube in a bottle placed underneath, and the nitrogen removed in solution determined, gave similar results, the gains being respectively 0.1387 and 0.1671 grm. of nitrogen. The increases in these three cases amount to 8.6, 7.3, and 8.8 per cent. respectively of the total combined nitrogen present at the commencement, and a comparison of the last two with the first shows that the ammonia of the air and the nitrogen carried to the soil by rain are negligible quantities in these experiments. The gain of nitrogen per hectare of soil, for the same depth (18 centimetres) and for the same time (8, 12, and 11 weeks), would amount to 87, 74, and 89 kilos, respectively, and in experiments with other soils much larger increases have been obtained, but the author does not assert that the conditions necessary for these large increases are present over large areas or depths of land under ordinary circumstances.

The influence of leguminous vegetation is best shown in the series of experiments with a glass shelter, or with free exposure to air, since it is impossible to get a healthy development of the plants in the saturated atmosphere under the glass shades, even though carbon dioxide be occasionally introduced and the air renewed. The following table gives the results as regards nitrogen obtained by growing six leguminous species in the same soil as above-mentioned in pots placed under a glass shelter with free circulation of air:—

	Pot 40. Vetches.	Pot 41. Lupins.	Pot 42. Lathyrus.	Pot 43. Medick and Anthyllus.	Pot 44. Crimson Clover.	Pot 45. Lucerne.

Gain per cent. of total nitrogen	21.3	6.1	20.0	33.7	10.5	37.5

Experiments made with free exposure to air and rain gave similar results. It will be noticed that in each case the soil shows a gain of nitrogen, in addition to the generally large gain shown by the plants. The latter gain is generally as great in the roots as in the parts above ground. In most cases the soil was exhausted of the small quantities of nitrates originally present, and those formed during the progress of the experiments. A noteworthy feature is the very large quantity of mineral matter taken by the roots from the soil, the ash of the roots amounting in most cases to over 80 per cent. of the dry matter. In most cases tubercles were developed on the roots of the plants. Experiments made on the fixation of nitrogen by soil alone, the soil being watered with an extract of some of these tubercles, showed that at any rate the tubercles alone, without the growth of the plants to which they are naturally attached, have no power to increase the amount of nitrogen fixed.

To sum up these experiments, they were 64 in number, made with prepared samples of three different soils of different degrees of richness in organic matter; these soils were tried alone under the three conditions of closed shades, glass shelter with free access of air, and no shelter; and under the same three conditions, as far as practicable, with the six species of leguminous plants above mentioned. The results were all of the same sense as those already cited, a gain of nitrogen by the soil alone and by the plant and soil, and in the latter case the gain was shared by both above- and underground portions of the plant, and this gain must in all cases be attributed to fixation of free atmospheric nitrogen. The different leguminous plants, however, showed very different degrees of development in the various experiments, the gain being generally greatest with lucerne, which flourished well and afforded two cuttings, whilst the lupins developed the worst of all. The author's results confirm to a great extent those of Hellriegel and Wilfarth.—J. M. H. M.

On Putrefaction and the Formation of Dung Heaps. J. Reiset. Compt. Rend. **108**, 708—712.

In view of some recent experiments of Schlösing, the author directs attention to his own experiments of 1854—1856, showing that free nitrogen gas is always disengaged during the putrefactive decomposition of nitrogenous organic matter.—J. M. H. M.

Richness of Wheat in Gluten. E. Gattelier and L. L'Hôte. Compt. Rend. **108**, 859—862; 1018—1019; and 1064—1066.

The flour from four samples of the same variety of wheat, grown on the same soil, but with different quantities of nitrogenous manure, gave the following percentages of gluten ($N \times 6.25$) calculated on the dry matter; 10.43, 11.37, 12.75, 11.31. The dressings of ammonium sulphate were 100, 200, 300, and 300 kilos. per hectare respectively. The entire wheat of these samples contained the following percentages of gluten, 12.56, 12.68, 13.75, and 12.75; so that the richness in gluten of the flour follows the same order as that of the entire grain. The previous cropping also influences the proportion of gluten, which is higher the more nitrogen is left in the soil.

Twelve varieties of wheat, grown at the same time, on the same soil, with the same manuring and previous cropping, gave percentages of gluten from 9.56 to 14.18 (dry). The winter wheats were poorer than the spring wheats, and varied from 9.56 to 12.00. There was no relation between the yield of wheat and its richness in gluten.

From a number of observations, the authors conclude that the manuring has more influence on the yield of gluten than the variety of wheat has, and that by giving as much nitrogenous manure as can be safely applied without danger of laying the crop, and at the same time selecting a variety which yields a large crop, productiveness can be combined with richness in gluten.—J. M. H. M.

Formation of Nitric Deposits. A. Muntz and V. Marcano. Compt. Rend. **108**, 900—902.

Caves containing deposits of earth with from 4 to 30 per cent. of calcium nitrate, and 5 to 60 per cent. of calcium phosphate, are common in Venezuela, not only in the littoral mountain chains, but also on the flanks of the Cordillera of the Andes. In these deposits are embedded remains of mammalian bones, preserving their form, but so friable as to fall to powder when they are extracted. They consist solely of calcium phosphate; the gelatin has been nitrified and dissolved out, and the calcium carbonate of the bone has been used up in neutralising the nitric acid produced. The nitric ferment is found in abundance throughout the deposits, in a very well developed form. Some of these deposits are 10 metres thick.—J. M. H. M.

Proportion of Nitrates in the Rain of Tropical Regions. A. Muntz and V. Marcano. Compt. Rend. **108**, 1062—1064.

One hundred and twenty-one samples of rain collected at Caracas, 1883—1885, gave as a mean 2.23 mgrms. of nitric acid (N_2O_5 ?) per litre, the maximum being 16.25 mgrms. and the minimum 0.20 mgrm.

Nineteen samples collected at St. Denis, Réunion Island, 1886—1887, gave as a mean 2.67 mgrms., maximum 12.5 mgrms., minimum 0.4 mgrm. These figures are much higher than those found for Alsace by Boussingault, and for England by Lawes and Gilbert, and as the tropical rainfall also is much greater than that in temperate climates, it follows that the nitric acid carried down to the soil by rain is not in the tropics a negligible quantity, as it is here.—J. M. H. M.

Culture, Varieties, and Diseases of Hops practically considered. C. F. Thatcher. Trans. Laboratory Club, **1**, 84—86.

Rice loamy soils are suitable for hops, but apparently no general rules can be laid down for the selection of soils for this crop. The application of high farming, involving the use of large quantities of artificial manures, is deprecated, as they are stated to increase the crops with a very considerable sacrifice of quality. Training on poles is more economical than training on wires, but the latter have the advantage of not offering a harbour for certain insects; string has been used with success for hop training. Washes composed of infusions of elder leaves, soap, tobacco, and quassia, also sulphur and paraffin, are used for destroying pests and preventing disease. The aphids, which migrate from the plum to the hop in the spring and, *vice versa* in the autumn, is the worst parasite, the red spider, which is sometimes green and also brown, coming next, whilst there are about half a dozen insects injurious to hops. Of English hops cultivated in Kent and Sussex, Goldings are the best, then come Grape, Jones', and then the Colegate at once the most hardy, most prolific, and most inferior. The White and Green Bine hops are grown in Surrey, Hants, and Worcestershire. The "Brambling," Bass's, Tuggle's, White's "early" and "early prolific" are inferior varieties of the true Goldings. Jones' hops require picking as soon as ripe, as they then drop their petals and are hence known as "flyers." Hops discoloured during growth by sun after heavy dews, although deficient in colour, appear to retain their flavour and keeping qualities intact, and should not be discarded by brewers. It is always better to use small quantities of good hops than large quantities of an inferior quality. There is, it seems, little or no connexion between the keeping powers of ale and the quantity of hops used. English hops are packed by the growers and can be depended upon as being of the district marked on them, a fact not so certain in Continental hops, which are packed by the merchant.—D. A. L.

Decomposition of Albuminoids in Plants in the Absence of Free Oxygen. W. Palladin. Ber. d. Bot. Gesell. **6**, 205—212; 296—304.

MANY investigators have proved that decomposition of albuminoids in plants takes place in the open air, but owing to their constant reproduction from the carbohydrates which accumulate in plants, this decomposition cannot be readily perceived. If, however, the supply of carbohydrates is cut off by exposing the plant in a dark room, then the decomposition of the albuminoids proceeds vigorously, the chief and almost only product being asparagine, showing that the decomposition is really oxidation.

In the absence of free oxygen green plants do not suffer loss of albuminoids during the first 20 hours, provided they contain sufficient non-nitrogenous matter. If, however, they have been deprived of most of their non-nitrogenous matter by detention in a dark room, then also they lose a considerable proportion of their albuminoids during the first 20 hours' exposure in a place free from oxygen the chief products of this decomposition being leucine and tyrosine, asparagine being formed only in small quantities.—D. A. L.

Acidity of Cell-Juice. Lange. Forschungen auf dem Gebiete d. Agrikulturphysik, **11**, 111—116.

THE author's investigations on the variation of the acidity in the cell-juice of plants have led him to conclude that in the morning an increase of acidity is observed as compared with the preceding day, whilst in the evening the acidity is less than that of the preceding night. The loss of acid during the day proceeds more energetically in the red half of the spectrum than it does in the blue half.—D. A. L.

Cultivation of Sugar-Beet. H. Briem. Oesterr. Ungar. Zeits. f. Zuckerind. u. Landw. **17**, 1888, 571—578.

SUGAR-beet was cultivated from the same seed on a rich garden soil made up of pond mud, and on a poor soil with a very thin layer of mould and a stony subsoil. In the former case large watery roots were obtained; in the latter they were small and ill-developed; whilst in both cases the quality was much inferior to that of the roots usually produced from the seed employed. From this it is inferred

that good seed alone will not ensure a good quality of crops, but that in addition careful cultivation, favourable climate, and suitable soil are required.—D. A. L.

Manurial Value of Different Phosphates. T. Poggi and P. Maissen. Le Stazioni Speriment. Agrar. Ital. **15**, 583—584.

MAIZE was grown on a sandy calcareous clay soil without manure, with bone-meal alone, with bone-meal and ammonium sulphate, with bone-meal ammonium sulphate and potassium chloride; a similar series of plots being arranged with mineral phosphate in place of bone-meal. The experiments were made in duplicate or even triplicate, and the mineral phosphate was found to be nearly as good as the bone-meal when similar proportions of each were used. The best result was obtained with a dressing of 300 kilos. of bone-meal and 160 kilos. of ammonium sulphate per hectare.—D. A. L.

Fertilising Subsoil. G. de Marneffé. Bull. de la stat. agronom. de l'Etat à Gembloux, **42**, 13—18.

TO facilitate the fertilisation of the subsoil recommended by some agriculturalists, the author has constructed a plough which makes a furrow twice the ordinary size and throws the ridge twice the usual distance; the surface of subsoil thus exposed is then ploughed with an ordinary plough, or may first be dressed with manure, then by refilling in the reverse order any admixture of subsoil with surface is avoided. The subsoil is in this way exposed to the air and can be manured, without in any way affecting the surface soil.—D. A. L.

Digestibility of the Nitrogenous Constituents of Sugar-Beet Residues and some other Feeding-Stuffs, when Fresh, Dry, or as Silage. A. Morgan. Jour. f. Landw. **34**, 1888, 309—323.

THE author has made a great many artificial digestive experiments, by digesting various fodders with pepsin and pancreatic juice. Some of the results are given in the following table:—

Fodder.	Percentage of Total Nitrogen.		
	As Albuminoids.	Digestible.	
		Total.	As Albuminoids.

The author remarks that the nitrogenous matter in sugar-beet residues is not all digestible as is frequently supposed; moreover, the digestibility is not altered by drying at moderate temperatures, but is diminished by temperatures above 125—130°. He also draws attention to the fact that unlike other feeding-stuffs the digestibility of the nitrogenous constituents of sugar-beet residues does not decrease by ensiling. The digestibility of many other fodders has been tested, and the results are tabulated in the paper. The following are a few of the digestibility-coefficients ascertained: Straw of cereals, 29.4; straw of leguminosae, 62.80; chaff, 36.20; meadow hay, 76.60; clover hay, 83.80; lucerne hay, 88.5; barley groats, 72.7; wheat

bran, 76.6; cotton-seed cake, 93.0; earth-nut cake, 94.6; palm-nut cake, 76.9.—D. A. L.

Composition and Digestibility of certain Fodders, and Observations on the Determination of the Digestibility of Albuminoids and Carbohydrates. W. A. Jordan, J. M. Bartlett, and L. H. Merrill. *Agricultural Science*, 1888, 283—302.

The following results were obtained by the usual methods. Nitrogen by the Kjeldahl's method; crude fibre by the Weender method, and so on, from American (Maine) plants:—

Experiments on the digestibility of these fodders were tried with sheep. The sheep were kept in stalls and fed for twelve days on each of the different materials. After seven days' feeding the faeces were collected for five days,

sampled and analysed. The results are given in detail in the original and are epitomised in the following table, the material in the faeces being regarded as undigested:—

As a control of these results, artificial digestion experiments were tried according to Stutzer's process, by digesting with pepsin (made from dry preparation) and pancreatic juice at 40° C.; the pancreatic juice was prepared by

Chittenden's method and the digestion in it was carried on for 12 hours. In the following table are given the results, in column A, from the feeding experiments, in column B, from the artificial digestion.

The differences in the results are attributed to the inclusion of nitrogen derived from digestive fluids and wear and tear of tissue in the numbers for undigested nitrogen in the analysis of the faeces, and experiments were made to confirm this view. To remove the nitrogen derived from wear of tissue, &c. without attacking the undigested nitrogenous matter, the faeces were treated with various solvents in succession—ether, alcohol, hot water, and cold lime water. The feeding results, when corrected on this basis, are given in column C. of the above table. In other experiments digestion for 24 hours with gastric juice was applied to the faeces for the

removal of tissue, &c. nitrogen, but nitrogen continues to be dissolved by this method throughout the 24 hours, and the quantities are probably too high. The results from the feeding experiments corrected on this basis are given in column D. of the above table. If six instead of 24 hours digestion with gastric be taken, the results are almost exactly the same as under B. These results are valuable as indicating sources of error in digestion experiments. The following table shows the relation the nitrogen in the faeces derived from the animal juices, tissues, &c. bears to the albuminoids consumed and to the organic matter digested.

TABLE IV.

Name of Plant.	Daily Consumption of Albuminoids.	Organic Matter digested Daily.	Nitrogen dissolved from the Faeces, &c. by the Treatment with Solvents.—Per Cent. of the Albuminoids Consumed.
	Grams.	Grams.	
Alsike clover (full bloom).....	88.8	349.5	1.30
White clover	105.8	374.0	1.32
Blue joint grass	64.3	251.5	1.97
Cock's foot grass.....	52.5	323.7	2.32
Oat straw.....	12.5	158.6	4.80
Oat straw and raw potatoes.....	38.9	312.6	3.42
Common bent grass.....	59.8	347.6	1.27
Timothy (1887) grass	52.5	408.9	1.50
Wild oat grass	48.0	378.9	2.27
Couch grass	59.5	360.1	1.59
Crow foot.....	63.4	331.3	1.45
White weed	59.1	350.7	1.22

These data demonstrate that the quantity of nitrogen in the faeces arising from juices, &c. depends on the extent of work imposed on the digestive system, and not on the proportion of nitrogen in the food; in fact, as a rule, it seems that the lower the proportion of nitrogen in the food the larger will be the quantity of this nitrogen in the faeces. This accounts for the great discrepancies between some of

the numbers in columns A, B, C, and D, in Table III.; those for oat straw, for example.

In estimating carbohydrates, cognisance has been taken of the fact that some are readily digestible, and others are not. Therefore determinations of cane-sugar, of grape-sugar, and of starch were made in the fodders, and of starch in the faeces. Some of the results are given in the following table:—

TABLE V.

—D. A. L.

Formation of Organic Acids, Nitrogenous Organic Matter, and Potassium Nitrate in different Parts of the Beet-Plant. H. Leplat. *La sucrerie indigène*, 1888, 415.

INVESTIGATIONS on this subject have led the author to conclude that neither potash, lime, nor ammonia are present in the plant either in a free state or as carbonates; but that more probably the bases taken by the roots from the soil in the form of acid carbonates reappear in the leaves and roots as organic nitrogenous compounds, as nitrates and as salts of organic acids. The author does not state how the nitric acid gets into the plant.—D. A. L.

PATENT.

Improvements relating to the Preparation of Artificial Manures from Fish and other Substances, and to the Extraction of Oil therefrom. C. Weigelt, Berlin, Germany. Eng. Pat. 11,505, August 9, 1888. *Id.*

THE animal substances are treated with a solution containing potassium chloride or sulphate or magnesium sulphate. The "juice" is separated by pressure and the residue left to dry in the air. It is then ground. If much fat be present it will be expressed with the juice from which it may be recovered; or the dried material may be treated in an extraction apparatus.—E. J. B.

XVI.—SUGAR, STARCH, GUM, Etc.

Record of Experiments conducted by the Commissioner of Agriculture in the Manufacture of Sugar from Sorghum in 1888. H. W. Wiley, U. S. Department of Agriculture. Bulletin, 20.

THIS pamphlet contains very full details of all the work done in connexion with this industry at the five sugar factories, Rio Grande, N.J.; Kenner, La.; Conway Springs,

Douglas and Sterling, Kans., along with general conclusions, which have been derived from a study of the results obtained, and suggestions for the better working of the industry in the future.

The reports from the superintendents and chemists of each station are given in full, and will be found of great interest and value to persons who have any connexion with this industry.

Many of the reports indicate comparative failure, but all the writers unite in prophesying a good future for the sorghum sugar manufacture, and can point to many difficulties already overcome, and are confident of ultimate success.

The application of the principle of diffusion has been the first step towards making this a possible industry, and excellent results are now obtained so far as the extraction of the sugar is concerned.

One great trouble is the vagaries of the sorghum plant, which requires the constant supervision of the chemist, and great stress is laid on the necessity of improving the quality of the cane to be used, by careful seed selection and cultivation, so as to ensure a high and uniform yield of sucrose; and, in the light of the success that has attended the cultivation of the sugar-beet, it is not too much to expect that the sorghum may be similarly improved.

So far as experience goes, a soil and climate similar to those of Southern and Western Kansas appear to be best suited to the culture of sorghum for sugar-making purposes.

The juice as it comes from the diffusion cells has to be filtered to remove the particles of suspended matter, and after many experiments it was found that a shallow filter of coarse sawdust answered the purpose best, one bushel being sufficient to filter the juice from 15 tons of cane.

By dusting finely-powdered air-slaked lime in the chips as they left the shredder, in the proportion of one quart to 1,100 lb. of chips, inversion during diffusion was entirely prevented.

At the Conway Springs factory the average amount of sugar per ton of cane was 249 lb. One analysis of cane showed 13.85 per cent. of sucrose and 1.01 per cent. of glucose, and this is considered the highest yet produced.

Another difficulty that has yet to be overcome is the separation of the sugar from the juice. This is prevented to a large extent by the gum, starch, &c., which it contains, as well as the glucose, so that in the before-mentioned factory only 100 lb. of sugar were obtained out of a possible 249 lb.

The last report of the work done at the Sterling experimental station is specially devoted to the consideration of the faults of the sorghum plant and the best means of improving it, together with much interesting analytical data and results of experiments with the known varieties; and it is pointed out that sorghum has advantages over both the sugar-cane and the sugar-beet in selecting seed from the best individuals. Sugar-beet is a biennial plant requiring two years to produce its seed, whereas sorghum is an annual, requiring but one year to mature its seed, consequently progress in its improvement should be twice as rapid. Further, "the sorghum is unique among sugar-producing plants, in that its seed may be separated entirely from the cane, and the latter analysed, giving exactly the worth of the individual which produced the seed without injury to the seed itself," and the authors think "it would be criminal folly on our part if we failed to avail ourselves in the sorghum industry of the advantages naturally possessed by the plant, and of the lessons taught us by the experience of others with the beet and cane."—W. M.

New Processes and Apparatus for Sugar Manufactories. Stammer. *Dingl. Polyt. J.* 272, 128—141.

Investigation of Sugar in Aqueous Solution.—In connexion with his previous investigations on the influence of dilution in the testing of aqueous sugar solutions (see this Journal, 1888, 591), Pareus points out that the following method of procedure is necessary:—10 grms. of sugar are dissolved in water, made up to 50 cc. and filtered. 25 cc. of the filtrate are run into 50 cc. of boiling Soddani solution, heated for five minutes and filtered. Should clarification with lead acetate be found necessary, 20 grms. of the substance are dissolved in water, lead acetate added, the solution made up to 50 cc. and filtered, 25 cc. being transferred to a 50 cc. flask, the lead precipitated with sodium carbonate, the liquid made up to 50 cc. and filtered again, 25 cc. of the filtrate being used as above for the purposes of testing. Pareus points out that (in contradistinction to what takes place with Fehling solution) alkaline sugars almost always, under these circumstances, cause a turbidity on being boiled; this turbidity being due to the lime which is not completely precipitated by the sodium salts. It is therefore necessary to filter the solution after boiling, before any conclusion as to the precipitation of cuprous oxide can be arrived at.

Investigations on the Structure and Development of the Beet-root Nematoids (Heterodera Schachtii).—A. Strubell has observed that the eggs of the nematoids are killed in a short time in a mixture of glycerol and water, in a 3 per cent. salt solution, and in a weak picric acid and chromic acid solution. The nematoids themselves were able to exist in a 3 per cent. solution, but died off after two days in a 5 per cent. solution. Willot has also made the latter observation, and believes that it might be employed for the destruction of these parasites. The use of such a strong salt solution will probably be found objectionable from an agricultural point of view, and Strubell's observations on the destruction of the eggs may be found to possess more practical importance.

Lixivation of Mud in Beet-root Sugar Works.—Since Lippmann has shown that the polarising substance contained in the last washings from the mud of the beet-root sugar manufacture consisted of the more highly polarising substance galactose and not of sugar, the question has arisen whether after all it is right to lixiviate the mud as completely as possible. For this purpose A. Herzfeld has examined two samples of mud from a Silesian factory, one lixiviated the other not, and it appears that as the quantities of active non-sugars present in muds of this character are not worth mentioning, lixiviation should be carried out as far as possible.

Influence of the Alcohol Method in the selection of Beet-roots.—The wide distribution of raffinose in the products of sugar manufacture is now well known, and as the detection of raffinose in presence of sugar is impossible by means of the alcohol method, the question has very naturally arisen whether the selection of beet-roots for seed by this alcohol method, giving high polarisation results, has not unintentionally led to the excessive accumulation of raffinose in the descendants. A. Herzfeld has carried out experiments on the subject, and in the cases he has investigated he has found that the selection of beet-roots for seed purposes by the alcohol polarisation method did not tend towards the accumulation of raffinose. This is not, however, intended to indicate that raffinose, or at any rate polarising non-sugars, were totally absent.

Raffinose a Natural Constituent of Beet-roots.—It has been variously asserted that the presence of raffinose in sugar is due, in certain methods of sugar manufacture, to the employment of a large excess of alkaline earths, which are said to cause its production from other compounds. In connexion with this subject, v. Lippmann has been continuing his investigations on raffinose, and has succeeded in obtaining raffinose in appreciable quantity from beet-sugar prepared by the osmosis method, a method therefore in which neither lime nor strontia are employed. It consequently seems to be no longer doubtful that raffinose is a natural constituent of beet-roots, though of course it cannot be asserted that it occurs in all beet-roots or that the amount in them is invariably the same.

Sugar Candy Manufacture. J. Bock.—The crude sugar employed should be as good as possible. This is melted, filtered through large quantities of bone-black, and then subjected to a preliminary concentration in vacuo. Since the specific gravity cannot be determined in the vacuum pans, either directly or by means of the boiling point, as the latter is subject to considerable fluctuations, the last portions of water are usually driven off in open pans with double bottoms and provided with direct steam coils. By this means the right degree of concentration, which is very important in candy manufacture, can be accurately determined. The boiling point lies between 112°—115° C. The solution is then run into the candy pots by means of a receiver. These pots are usually conical copper vessels. The threads on which the candy is to crystallise are either attached to copper or iron frames, or else they traverse the pots and are threaded through holes in the pots which are separately closed with clay, or the whole of the outside of the pots is pasted over with paper.

The pots are placed in stoves, and should be filled up as quickly as possible to prevent their cooling before the stoves are closed. The solution in the pots is sufficiently hot to raise the temperature of the stove to the proper point. After 8—10 days the stoves have cooled down to 35°—30° C. They are then opened, the pots removed, the thin crystalline crust on the top broken through, and the mother-liquor poured off the crystals through sieves.

Some pots are made large enough to hold one brew, in which case they are fixed in the stove and the mother-liquor is let off through a valve at the bottom. To prevent crystallisation on the sides as far as possible, the pots are washed thoroughly clean, but are not scoured bright, as the radiation from the bright parts is too rapid. The candy crystals are next washed with luke-warm water, dried, sorted and packed; 48—52 per cent. of the sugar is thus obtained as candy. The mother-liquor is usually worked up into other forms of refined sugar. It can, however, be employed again for candy manufacture three or four times, according to the quality of the crude sugar used. Of course the impurities of the sugar accumulate in it. The chief impurity of colonial sugar is invert sugar; the chief impurities of beetroot sugars are the salts contained in them. Sugars containing difficultly soluble salts (the principal one is potassium sulphate) should be avoided, as they go down with the candy and give it a salty taste; the more soluble salts do not matter. As much crude sugar as dissolved in the mother-liquor as has crystallised out as candy, a little water being added. The solution is then concentrated and treated as described above. However, even when almost pure sugar is used, there is a limit to the re-employment of

the mother-liquor, as a portion of the sugar always loses its power of crystallisation through heating. This influence is very clearly marked by the crystals becoming smaller and insignificant.—F. W. T. K.

Diffusion Experiments. Herzfeld. Zeit. f. Zucker. Ind. **39**, 304.

In the extraction of beet by diffusion a considerable quantity of salts passes into the syrup along with the sugar. Solid organic and inorganic constituents of the marc also dissolve in quantity which increases with the duration of heating, the number of vessels heated, and the slower circulation of the syrup. With thick sections the battery must be longer and the number of heated vessels must be increased in order to effect complete extraction. It follows that the resulting syrup will be richer in ash. An increase of temperature to 65°–85° in the middle of the battery is not so injurious as might be expected. Feebly ammoniacal water may be used with advantage.—C. H. B.

PATENTS.

Improvements in the Acid Saccharification of Amylaceous Substances. A. H. J. Bergé, Brussels, Belgium. Eng. Pat. 9320, June 26, 1888. 8d.

THE author finds that for a given temperature, duration of process and quantity of acid, the saccharifying action of acids on starch bodies becomes more rapid and complete in proportion as the pressure is increased. This principle is practically applied in the saccharification of starch by sulphurous acid. The operation is conducted in closed vessels, and the requisite pressure is obtained by forcing in carbonic acid, nitrogen, or some other non-oxidising gas.

—A. J. K.

Process for Manufacturing Colourless Maltose Syrup. O. Leuz, Berlin, Germany. Eng. Pat. 76, January 2, 1889. 4d.

THE saccharification of pure potato-starch or rice-starch is effected by a malt extract at a temperature of about 50° C. and under a pressure of three to four atmospheres. The temperature is then raised to 70° C. for the purpose of eliminating most of the vegetable albumen. After some time the solution of maltose, which is now of a brown colour, is filtered from the precipitated albumen and boiled to precipitate the remainder of the albumen. The juice is filtered again, first through fine cloth, then through bone-black. A clear limpid juice is obtained, which is evaporated to 25° B., filtered again through bone-black, and finally through fine cloth. The final syrup has a pure sweet taste and is colourless and odourless.—A. J. K.

A Novel Method or Process for the Manufacture of Gluten and Starch. H. Barker, Somerville, Mass., U.S.A. Eng. Pat. 4741, March 19, 1889. 8d.

THE cereal, preferably wheat, is pulverised to the form of a flour, and the flour is mixed with water to a semi-fluid or pasty mass. The paste is then forced through a perforated plate and the depending bars or threads are cut by a special appliance into short lengths and dropped into a vessel containing water. After agitation for some time the gluten settles to the bottom of this vessel, and the starch remaining in suspension is drawn off from the top of the tank with the water, into large settling vessels, in which the starch is separated by subsidence.—A. J. K.

XVII.—BREWING, WINES, SPIRITS, Etc.

Effect of Carbon Dioxide on the Growth and Activity of Yeast. G. Foth. Woch. f. Brauerei. **6**, 263.

THE presence of carbon dioxide in wort, whether under ordinary or increased pressure, retards fermentation to a considerable extent. This effect increases with the quantity of gas dissolved in the liquid, and consequently with a reduction of temperature or an increase of pressure. Different species of yeast are affected in different degrees; *Saccharomyces pastorianus*, for example, will grow in presence of a quantity of carbon dioxide sufficient to prevent the action of other species.

These facts have considerable bearing on the preservation of beer. Saturation with carbon dioxide causes more complete settling of the yeast, and a further development of it, and hence the beer can be obtained quite clear. The quantity of gas necessary varies with the strength of the wort and the species of the yeast. It must be borne in mind that the presence of carbon dioxide may affect the taste of the beer, especially in the case of full-flavoured varieties.

—C. H. B.

Combination of Malt with Water. W. Schulze. Chem. Zeit. Rep. **13**, 126–127.

WHEN malt is moistened with water, it combines with part of the latter, and this combination is the cause of the well-known development of heat. When the moistened malt is mashed there is a further development of heat. The combined water partly passes into solution in the wort and partly remains behind in the grains. The usual assumption that the specific gravity of malt is 1.333, and its specific volume 0.75, is inaccurate; the specific volume of the malt used by the author was 0.6877. The proportion method commonly used for the estimation of extractive matter gives results which are always more than one per cent. too high, but if a correction be made for the water which enters into combination, the results are more accurate. An approximate correction may be made by subtracting 1.2 from the percentage of extractive matter as usually determined in this way. The sum of the true volumes of the wort and grains is equal to the sum of the true volumes of the malt and water before mashing.

—C. H. B.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

Alcoholic Fermentation of Milk. Martinand. Compt. Rend. **108**, 1067–1069.

THE author finds that coagulation of the casein takes place under certain conditions when the alcoholic fermentation is excited in milk or milk and water by any of the following ferments: — *Saccharomyces cerevisiae*, *S. ellipsoideus*, *S. pastorianus*, *S. apiculatus*, and Duclaux yeast, and this whether the added sugar be glucose or sucrose; with the exception of *S. apiculatus* in a solution of sucrose the coagulation is not due to acid products of fermentation, for the fermented liquids, passed through a Chamberland filter, are incapable of coagulating the smallest quantity of fresh milk. To produce the coagulation there must be a sufficient proportion of fermentable sugar present.—J. M. H. M.

PATENT.

Improvements in the Manufacture of Seed Cake or Cattle-Food from Cotton Seed. R. S. Baxter and G. D. MacDougall, Dundee. Eng. Pat. 15,813, November 2, 1888. 6d.

THE cotton fibres with which many varieties of cotton seeds are ordinarily covered, render cake made from such seeds unsuitable for cattle food, if the fibres be present therein in their natural condition. The improved process consists in first moistening the cotton seeds with dilute sulphuric acid, heating or drying and finally removing soluble matters by washing. By this means the cotton fibres are rendered innocuous.—A. J. K.

(C)—DISINFECTANTS.

Antiseptic Properties of Hydroxylamine. G. Marpmann. Pharm. Centr. N.F. 10, 245.

HYDROXYLAMINE is a very powerful antiseptic. One part in 5,000 prevents fermentation even in a liquid rich in organic matter and containing readily fermentable substances. One part in 30,000 prevents the development of germs in cultivation-gelatin.—C. H. B.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

Improvements in the Manufacture or Treatment of Paper. C. Morfit, London. Eng. Pat. 8148, June 19, 1886 (Amended Specification.) 6d.

THESE have already been described in this Journal, 1887, 558. The inventor now restricts himself to the use of Irish Moss or Agar-Agar, while the description of the improvements is modified.—O. H.

Improvements in Machinery or Apparatus for Treating, Washing, Cleansing, Discharging, Bleaching, Drying, and Softening Fibrous and Textile Materials. E. Brasier, New Cross. Eng. Pat. 6570, May 2, 1888. 8d.

THE improvement consists in causing a carriage furnished with rollers to travel to and fro along a vessel, at the bottom of which the material to be treated is placed. When intended for drying the rollers may be heated. Suitable arrangements are supplied for filling the tank with water or other liquid.—E. J. B.

Improvements Connected with the Carbonising of Woollen, Silk, and other Rays and Fibrous Materials. G. Solson, Dewsbury. Eng. Pat. 8931, June 19, 1888. 8d.

THE inventor introduces improvements upon his original invention of a carbonising machine (Eng. Pat. 6254 of 1887). They consist chiefly in the addition of a fan for drying the material before carbonisation in order to prevent the condensation of moisture upon the material to be treated.—E. J. B.

Improvements in Preparing Pulp for Paper-Making Machines and in Apparatus therefor. J. H. Annandale, Polton. Eng. Pat. 9106, June 22, 1888. 11d.

ESPARTO or other fibrous material boiled in the usual way is conveyed to an improved breaking engine where it is made into half-stuff. It then passes through a box to the save-all, from thence to a vessel where it meets with a stream of hot water, and into one or other of a set of improved bleaching vessels. The bleached material passes through a box on to a coarse strainer, sand tables, a fine strainer, and then through another box into the save-all. From this it falls into trucks. The bleached half-stuff is conveyed by the

trucks to a vessel similar in construction to the bleaching vessel. Here it is mixed with rosin size. It then passes through a beater similar to the breaking engine, thence to the chest, where the starch, clay and alum are added. The pulp is now ready to be made into paper in the usual way.

—E. J. B.

Improved Papers and Methods of Manufacturing the same. L. G. Danielson, Nygvarn, Sweden. Eng. Pat. 9321, June 26, 1888. 6d.

THE improved paper consists of two sheets, one sized and the other unsized, joined together. One vat contains sized pulp and another vat contains the unsized pulp. The two sheets are made on cylinders, and are united together in the usual way on a press blanket, as they pass under a roller. The sheet is then carried forward to the drying cylinders in the usual way.—E. J. B.

Improvements in Paper-Making Machines. J. H. Annandale, Polton. Eng. Pat. 9942, July 9, 1888. 8d.

THE object of this invention is to produce a jogging or slight but rapid up-and-down motion of the wire cloth, in addition to the horizontal motion usually imparted to it. For details the original specification must be consulted.

—E. J. B.

Improved Apparatus for the Treatment of Rhea or China Grass and other Vegetable Fibrous Matters. W. Hitchcock-Spencer, Hitchin. Eng. Pat. 10,633, July 23, 1888. 8d.

THE apparatus consists of a keir made of boiler plate and capable of withstanding steam pressure. The material to be treated is packed in cages covered with wire cloth, and so arranged that after treatment their sides can be forced inwards so as to exert a pressure on the material and express the liquor contained in it. These cages are rotated on a shaft which is connected by means of a clutch with a driving shaft. The keir is provided with suitable means for heating and for the supply of the necessary liquids for treating the material.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Conversion of Anhydro-ecgonine into Pyridine.

A. Einhorn. Ber. 22, 1362—1368.

REFERRING to his previous investigations, the author proves the relationship which exists between anhydro-ecgonine and pyridine. By heating anhydro-ecgonine and hydrochloric acid in a closed tube to 270°—280° C., he obtains a number of different products. The contents of 12 tubes were first distilled over with steam in order to separate the neutral bodies, mostly hydrocarbons. By making the solution alkaline, the smell of ammonia, methylamine, and pyridine bases were at once noticeable. By means of nitroso compounds he is able to separate a secondary and tertiary base. The secondary base forms a gold double salt which yields pyridine on distillation with zinc-dust. The tertiary compound, probably a tetrahydrated- α -picoline with a methyl radical linked to the nitrogen atom, expressed by the formula:—

By distilling larger quantities of anhydro-ecgonine with zinc-dust hydrocarbons and also pyridine are obtained, besides

an oily base. Pyridine is identified by means of gold double salt. The author concludes that the conversion of anhydrococcine into pyridine shows clearly that cocaine is a pyridine derivative. His researches enable him to place the different atoms in the cocaine molecule and therefore the task of finding the constitution of cocaine can be considered as solved.—O. J. S.

The Conversion of Coumarin Derivatives into Quinoline Derivatives. W. v. Muller and Fr. Kinklein. Ber. **22**, 1716—1718.

In a brief communication the authors describe the conversion of nitromethoxybenzylidene aldehyde into α -nitroquinoline by means of alcoholic ammonia. In order to determine whether the original product employed was a derivative of coumaric acid or coumarin it was oxidised with freshly prepared oxide of silver in alcoholic solution and yielded the monomethylether of nitro- α -coumaric acid, which was found to be identical with a compound prepared by "Perkins' reaction."

—O. J. S.

The Manufacture of Lemon Essences in Sicily.

"The Times," August 20, 1889, 7.

THE United States Consul at Messina, in a report on the cultivation of oranges and lemons in Sicily, describes the mode of manufacturing lemon essences. With three strokes of a sharp knife the cutter peels the lemon lengthwise and lets the peel fall into a tub under the chopping block. He then cuts the lemon in two and throws it from his knife into a bucket. He works with wonderful rapidity, and fills from 10 to 12 tubs with peel a day, and is paid 2½d. a tub, weighing 77 lb. His left hand and right index finger are protected with bands of leather. The fresh peel is soaked in water 15 minutes before the essence is extracted. Peel that has stood a day or two remains soaking from 30 to 40 minutes that it may swell and offer a greater resistance to the sponge. The workman holds a small sponge in his left hand, against which he presses each piece of peel two or three times—simple pressure, followed by rotary pressure. The women employed in this work run a piece of cane through their sponges to enable them to hold them more firmly. The outside of the peel is pressed against the sponge, as the oil glands are in the epicarp. The crushing of the oil cells liberates the essence therein contained. The sponge, when saturated with the essence, is squeezed into an earthen vessel held in the lap. The peel is so thoroughly pressed that not a single cell escapes. This is ascertained by holding the pressed peel to the flame of a candle; should it neither crackle nor diminish the brilliancy of the flame the cells are empty. This process yields, besides the essence, a small quantity of juice and fecia (dregs). The separation of the essence juice and fecia soon takes place if the vessels are not disturbed; the oil floats on the juice and the dregs fall to the bottom. These three products derived from the peel have no affinity with each other. As the essence rises to the surface it is skimmed off, bottled, and left to settle for a few days. It is then drawn off with a glass siphon into copper cans, which are hermetically sealed. After the essence has been expressed, a small quantity of juice is pressed from the peels, which are then given to oxen or goats, or thrown on the manure heap and well rotted, or they would make too heating a fertiliser. The yield of essence is variable. The industry is carried on five months in the year. Immature fruit contains the most oil. From November to April, in the province of Messina, 1,000 lemons yield about 14 oz. of essence and 17 gallons of juice. The essence is so valuable that the workmen are closely watched, for they are most ingenious in secreting it about their persons. Six men work up 8,000 lemons a day; two cut off the peel, while four extract the essence and obtain 136 gallons of lemon juice and 7 lb. of essence. Dealers sometimes adulterate their essences with fixed oils, alcohol, or turpentine, but these mixtures may be easily detected. The essence of sour orange mixed with the essence of lemon produces an aroma similar to that of the essences of bergamot.

Terpenes and Etheral Oils. O. Wallach. Ann. **252**, 91—105.

LAURENE and menthene, hydrocarbons occurring in oil of laurel and oil of peppermint, have been investigated by Brühl (Ber. **21**, 115) who, from a study of their physical properties, came to the conclusion that these compounds differed from all other known terpenes, but whether they were identical or not could not at the time be ascertained. They both boil at 173°—175°, and in this respect closely resemble citrene, dipentene, and isoprene, which are terpenes having the saturation formula $C_{10}H_{16}E_2$. As, however, they contain only one double link they do not belong to this class of compounds, and they also differ from the pinenes having the saturation formula $C_{10}H_{16}E_1$.

The author's investigations prove that laurene, and probably also menthene, have no existence, as is shown by the following experiments. Oil of laurel, obtained from the leaves, was carefully fractionated and separated into a portion boiling above, and a portion boiling below 180°. The latter was again repeatedly refractionated and separated into a small portion, boiling at 158°—168°, and three much larger fractions boiling between 170° and 178°, the lowest of which was found to contain oxygen. The fraction 158°—168° was treated with amylnitrite and hydrochloric acid and the resulting nitrosochloride, which melted at 101°—102°, decomposed with piperidine. A nitrosoamine melting at 118° was obtained, a result which proves that oil of laurel contains small quantities of pinene. The three fractions boiling at 170°—178° were mixed together, diluted with light petroleum, and hydrogen bromide passed into the solution, whereon a large quantity of a colourless compound was precipitated. The precipitate was separated by filtration, pressed, decomposed with alkali and the resulting oil fractionated. The portion boiling at 176° solidified when cooled in a freezing mixture and was proved to be cineol. Pure cineol can be easily isolated from oil of laurel by this method.

Oil of laurel, obtained from the berries, was investigated in a similar manner. It yielded a small quantity of a compound boiling at 161°—166°, which was proved to be pinene, and a larger quantity boiling at 171°—177°, which was proved to be cineol.

These results show that even the lower boiling fractions of oil of laurel consist principally of a mixture of pinene and cineol, the latter being present in by far the larger quantity. Laurene has, therefore, no existence, and the peculiar properties which were assigned to it by Brühl were due to the presence of cineol in the substance investigated.

Oil of Olibanum.—Stenhouse (Ann. **35**, 306) and Kurbatov (Ann. **173**, 1) investigated oil of olibanum and have described a terpene, olibene, which they obtained therefrom. This terpene is identical with levo-pinene. A sample of crude oil of olibanum was separated by fractional distillation into two principal portions boiling at 157°—160° and 160°—165° respectively. Both fractions were feebly levo-rotatory and were proved to contain levo-pinene. Another fraction boiling at 177°—179° was found to contain small quantities of dipentene.

Oil of Elemi, as the author has previously shown (Ann. **246**, 233), contains a considerable quantity of dextro-phellandrene which occurs in the fraction boiling below 176°. This hydrocarbon is identical with that obtained from fennel oil and from *Phellandrium aquaticum*. The fraction 175°—180° contains such a large quantity of dipentene that oil of elemi can be very conveniently employed for the preparation of dipentene compounds. Deville (Ann. **71**, 353) investigated a sample of oil of elemi which he found to be strongly levo-rotatory; this oil probably contained, besides dipentene, a levo-phellandrene identical with that recently found by the author in the so-called Australian eucalyptus-oil. (Compare Ann. **246**, 232.) Besides phellandrene and dipentene, oil of elemi contains large quantities of higher-boiling products, consisting of polyterpenes and probably also of compounds containing oxygen. In fractionating the oil the presence of a crystalline compound was repeatedly observed; this substance is probably closely related to the amyrin investigated by Vesterberg (Ber. **20**, 1212). A sample of Brazilian resin which the author

examined contained such a large quantity of amyrin that crystals of this compound could be obtained by recrystallising once from ethyl acetate.

Oil of Sage.—The investigations of Tilden (Ber. **11**, 1264, and **13**, 2088) and the author (Ann. **227**, 289) have already proved that the lower boiling portions of oil of sage contain a hydrocarbon similar to pinene. A sample of the oil was submitted to fractional distillation, the portion boiling at 158° — 168° , which formed only a small quantity of the whole, was almost optically inactive and contained large quantities of pinene. The fraction 174° — 178° consisted principally of cineol. The lower boiling constituents of oil of sage are, therefore, principally pinene and cineol, but the principal portion of the oil consists of oil of salvi, boiling at 201° — 204° , which will be further investigated.

Oil of Mace.—A sample of crude oil of mace which was strongly dextro-rotatory was submitted to fractional distillation. The lower boiling (up to 165°) fractions, which form a considerable portion of the whole, were almost optically inactive, and contained considerable quantities of pinene. As the higher boiling portions were strongly dextro-rotatory it is probable that both dextro- and levo-pinene are present in the lower boiling fractions, as will be shown in a future paper. The fraction boiling at 175° — 180° contained dipentene.—F. S. K.

Analysis of Cinchonas and Solubility of their Active Principles in Water, Alcohol and Dilute Hydrochloric Acid. E. Landrin. Compt. Rend. **108**, 750—753.

See under XXIII., page 641.

Ammonium Bromide. K. Thümmel. Arch. Pharm. 1889, **27**, 270. (Compare this Journal, 1889, 210.)

THE yellow colouration developed by acidifying ammonia to which bromine has been added is not due to the presence of an ammonium salt of an oxyacid of bromine, but to the formation of a bromide of ammonium bromide, $\text{NH}_4\text{Br} \cdot x\text{Br}$. If care is taken to keep the ammonia in excess the solution remains colourless when acidified, and the yellow colouration is only obtained when the ammonia has been almost completely neutralised with bromine. When a solution of this kind is allowed to stand, evolution of nitrogen takes place, and when this has ceased the liquid no longer gives a colouration with acids.

In order to obtain ammonium bromide which remains colourless when acidified, an excess of ammonia must be used, and the solution should be allowed to remain for some time before crystallisation.—C. H. B.

Camphor-Phenols. M. Desèsquelle. Rep. de Pharm. **45**, 202.

Fifty grms. of β -naphthol or 150 grms. of salol, as the case may be, and 100 grms. of camphor are finely powdered, mixed together, heated until completely fused, filtered, and preserved in well-closed vessels. The products thus obtained are insoluble in water, but are readily miscible with fats, essential oils, ether, and alcohol. They attack neither wood nor metal, and hence are especially suitable for preserving surgical instruments.

The camphor-phenols readily take up iodine in the cold, a common formula being "camphor-phenol" 90 parts, iodine 10 parts. They also readily dissolve cocaine hydrochloride and the cinchona alkaloids.—C. H. B.

Terpin Hydrate. G. Vulpius. Pharm. Centr. N. F. **10**, 289.

TERPIN hydrate, $\text{C}_{10}\text{H}_{16} \cdot 3\text{H}_2\text{O}$ melts at 116° , whilst terpin, $\text{C}_{10}\text{H}_{16} \cdot 2\text{H}_2\text{O}$ melts at 102° . Terpin hydrate dissolves at 15° in 250 parts of water, 10 parts of 90 per cent. alcohol, 100 parts of ether, or 200 parts of chloroform. A completely odourless product is difficult to obtain, and is best prepared by exposing the dried and powdered substance to the air until it has lost all odour, and then recrystallising it from hot alcohol.—C. H. B.

Coniceine. E. Lellmann. Ber. **22**, 1,000—1,004.

PIPERIDINE, as the author has shown, yields with hypochlorite of lime a chlorinated piperidine. With potash it decomposes, yielding a new base, and hydrochloric acid is split off as follows:—

This new base exists only in the form of vapour. At the ordinary temperature it polymerises, forming a dipiperidine, which crystallises readily. The author has experimented in the same direction upon α -methylpiperidine and coneine. Both compounds, on boiling with a solution of bleaching powder, yield colourless oils and give compounds analogous to piperidine. Potash splits off hydrochloric acid, and forms, in the case of coneine, a base *coniceine*, boiling at 171° , and having the formula $\text{C}_8\text{H}_{15}\text{N}$. It is a secondary amine, and as it does not polymerise, it has probably the formula—

The compound appears to be identical with Hofmann's α -coniceine, obtained by the action of bromine and potash on conine.

From these considerations, and from the fact that neither α - or β -coniceine have double molecules, it follows that they will probably have the following constitution—

in which case they contain an asymmetric carbon atom, and should possess active properties.—J. B. C.

On β -Ethyl- α -Stilbazol and some of its Derivatives. G. Plath. Ber. **22**, 1057—1063.

REFERRING to his investigations on the subject (Ber. **21**, 3086) on the action of benzaldehyde on aldehyde collidine, he obtains by reduction of this body, thus produced, by means of hydriodic acid or by Ladenburg's method (sodium and absolute alcohol) the compound $\text{C}_{13}\text{H}_{15}\text{N}$, or β -ethyl- α -stilbazoline.

The salts of this base do not crystallise well. The hydrochloride, platino-chloride, and gold chloride salts were prepared. The physiological properties of base are similar to those of the ethyl compound. Experiments made by Professor Falk gave the following results. The effects of α -ethylstilbazoline hydrochloride are very much the same as those of stilbazoline, for which latter 96.14 mgr. (taking 1,000 grms. of white mouse as a unit) are the deadly dose, whereas 100.4 of ethyl compound produce the same effect. It also causes violent cramps if injected even in not deadly doses. He further forms additional substitution products, dissolving the double linkage by addition of bromine, and also forming the diacetyl compound. On oxidation, the body yields isocinchomeronic and benzoic acids (Ber. **21**, 294).—O. J. S.

On Morphine. L. Knorr. Ber. **22**, 1113—1119.

CONTINUING his researches on the subject (Ber. **22**, 181, this Journal, 1889, 305; see also 1889, 475—476) he investigates the action of acetic anhydride on methylmorphimethine,

which seems to explain the position of two still doubtful carbon atoms and the indifferent oxygen atom in morphine. Besides yielding dimethylamine, the treatment of methylmorphimethine yields—

(1.) Acetyl-methylhydroxyphenanthrene (m.p. 131 described by O. Fischer and A. Gerichten).

(2.) An oily base which could be analysed by means of methyl iodide compound, and was found to be methylmorphimethine, which had not been attacked by the acetic anhydride.

(3.) β -hydroxyethyl-dimethylamine—

the link between methylamine and choline (Ladenburg's) dimethylethylamine (Ber. 14, 2108).

The author draws the following conclusions from these facts, which are of importance for the formula of morphine:

(1.) Morphine is a tertiary base.

(2.) It has a methyl group united with nitrogen.

(3.) In methylmorphimethine two methyl groups are united with nitrogen and the conversion of codeine into methylmorphimethine can only be explained by the splitting up of one nucleus, containing the morphine nitrogen as a link.

(4.) This seems to be confirmed by the fact that methylmorphimethine can combine with five more bromine atoms than codeine.

(5.) Morphine contains one phenanthrene nucleus, which must be partly reduced considering the high percentage of hydrogen in morphine.

(6.) Methylmorphimethine splits up into β -hydroxyethyl-dimethylamine and a phenanthrene derivative.

(7.) Morphine contains one phenol-hydroxyl, one alcohol hydroxyl, and one indifferent oxygen atom, probably in connexion with an ethereal compound.

(8.) The alcohol hydroxyl reserves its character in methylmorphimethine and only appears as a phenol-hydroxyl after the decomposition into the acetyl compound. He therefore proposes this formula:—

It remains undecided whether the alcohol-hydroxyl is connected with carbon atom * or **.—O. J. S.

On the Constitution of Ecgonine. C. Stöck. Ber. 22, 1126—1129.

THE author points out the importance of investigations on cocaine since it has become a valuable local anæsthetic. Most of recent researches were made on the relation which exists between cocaine and its decomposition product ecgonine. He continues the work commenced by Merck (Ber. 19, 3002, this Journal, 1887, 225), and confirms the idea that ecgonine, like most alkaloids, belongs to the derivatives of pyridine, and stands in near connexion to tropine, the decomposition product of atropine. By means of distillation with zinc dust and lime, he obtains α -ethyl pyridine, the same pyridine base which, according to Ladenburg (Ber. 20, 1647, this Journal, 1887, 487), bears a close relation to tropine. The distillation also yields hydrogen, water, methylamine, and carbonate of ammonia, which were identified as the platinum double salts. The distillate which separates into an oily and aqueous layer, yields, on further purification of the oil by means of KMnO_4 and redistillation, α -ethyl pyridine. The platinum-chloride crystallises in large prismatic tablets, which melt at 160° — 161° C.

—O. J. S.

Hydrastine. M. Freund. Ber. 22, 1156—1160. (This Journal 1889, 412; and 1887, 381, 449 and 611.)

DIACETYLHYDRASTINE-OXIME is formed by the action of acetic anhydride on hydrastine-oxime; much heat is evolved during the reaction. It separates in beautiful crystalline plates melting at 121 — 122° C., and soluble in hydrochloric acid, reprecipitated by caustic soda. Its constitutional formula is—

By saponification with caustic soda, one of the acetyl groups is removed. The new body crystallises with two molecules of water and melts at 90° C. The water is driven off at 100° C. The dry compound melts at 139 — 140° C. Its formula is—

By the continued oxidation of hydrastine in alkaline solution with potassium permanganate, hydrastinic acid is obtained. The acid is difficultly soluble in cold water, easily in hot water, from which it crystallises in splendid white broad needles, melting at 164° C. It is also soluble in alcohol and ether, scarcely soluble in chloroform. It is formed from hydrastine without the separation of carbon. It is mono-basic and its formula is $\text{C}_{11}\text{H}_{11}\text{NO}_5$. Its aqueous solution neutralised with ammonia gives no precipitate with solutions of silver or lead. Hydrastinic acid melts with evolution of carbonic acid. The melted residue dissolves almost completely in boiling alcohol, a small quantity being left which melts at 260° C. The solution deposits crystals melting at 215° C. The crystals are insoluble in sodium carbonate, but dissolve in sodium hydrate solution from which they are reprecipitated by hydrochloric acid. Hydrastinic acid, boiled with very dilute nitric acid, yields a beautifully crystalline substance melting at 230° C.—H. T. P.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Yellow Stains in Gelatin Negatives. A. Lainer. Phot. Corr. 26, 171—175.

THE yellow stain frequently observed in gelatin negatives which have been developed with alkaline pyrogallol may be due to one of three causes:—(1) Decomposition of the insoluble sodium silver thiosulphate, $\text{Ag}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3$, left in the film, owing to imperfect fixing; (2) the action of the carbon dioxide of the air on the soluble sodium silver thiosulphate, $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3$, left in the film owing to imperfect washing; and (3) the combination of the gelatin with brown products of the oxidation of the pyrogallol. In the first two cases silver sulphide is formed and cannot be readily removed, but its formation is prevented by using a sufficient quantity of thiosulphate to ensure formation of the soluble double salt, and then taking care that all the latter is removed from the film by thorough washing. The brown stain due to the products of oxidation of pyrogallol may be removed in the usual way by treatment with an acidified solution of alum, or, more conveniently, by using an acid fixing bath prepared by adding to the solution of sodium thiosulphate a quantity of a solution of sodium sulphite previously acidified with citric or tartaric acid. The fixing bath then contains free sulphurous acid. The proportion of acid to sulphite must be carefully regulated, otherwise the thiosulphate will be partly decomposed and

sulphur will separate. One litre of thiosulphate solution may be mixed with 70 cc. of a solution of normal sodium sulphite in 4 parts of water, previously acidified with 30 cc. of a solution of tartaric acid in 2 parts of water, or 40 cc. of a similar solution of citric acid. It is advisable to use the fixing bath as fresh as possible.—C. H. B.

Prints on Boxwood. Phot. Archiv. 30, 102.

THE surface of the wood is rubbed with a filtered solution of 8 grms. of white soap and 8 grms. of gelatin in 500 cc. of water to which some zinc oxide has been added. After drying, the surface is brushed over with a mixture of clarified albumen 30 grms., water 24 cc., ammonium chloride 1.2 grms., and citric acid 0.2 grms. It is then dried, flooded with a solution of 3.2 grms. of silver nitrate in 31 cc. of distilled water, the excess poured off, and the surface again dried. After printing under a negative in the usual way, the surface of the wood is immersed in a solution of sodium chloride and then in a solution of sodium thiosulphate, in order to remove unaltered silver salts.—C. H. B.

Application of Photography to the Measurement of Expansion. Le Chatelier. La Nature, 1888, 35.

THE substance is employed in the form of rods, and the temperature is measured by means of a thermo-electric couple of platinum and platinum alloyed with rhodium. The rod is photographed in its actual size by means of two objectives, each of which is opposite an end of the rod, the distance between them being exactly the length of the rod. The method is very sensitive, since the negatives can be measured to 0.01 mm., and it has the advantage of being applicable at high temperatures.

The coefficient of expansion of Bayeux porcelain was found to be constant between 0° and 1000°, its value being 0.0000096.—C. H. B.

XXIII.—ANALYTICAL CHEMISTRY.

Notes on Lead in Water. C. Rawson. J. Soc. Dyers and Colourists, 5, 58—61.

THESE experiments were made to clear up some points connected with the presence of lead in the Bradford water supply. Contrary to the often-quoted statement of Fresenius, it is found that carbonate of lead is practically insoluble in pure distilled water, but if free carbonic acid be present, it will dissolve to the extent of 5 grains of lead per gallon. The test used for the presence of lead was sulphuretted hydrogen water acidified with acetic acid, which gives a colouration with less than one-twentieth of a grain of lead per gallon. Phosphate of lead is insoluble in water, but sulphate of lead, again, in contradiction to the statement of Fresenius, dissolves in distilled water to the extent of 1.75 grains of lead per gallon. Numerous experiments were made, by enclosing samples of water in old and new lead pipes for 24 hours, which pointed decisively to the conclusion that it is the free carbonic acid in waters which enable them to take up lead in transit through pipes, and this is especially the case with waters containing any considerable quantity of carbonic acid above that required to form bicarbonates of the bases present. The presence of neutral nitrates or of humic acid was without appreciable

effect. The results of adding reagents to a water containing much free carbonic acid showed that its solvent action on lead could be stopped by the addition of sodium carbonate, calcium hydrate, sodium phosphate, or calcium phosphate. On taking the practical aspects of a treatment of the water on the large scale, the author gives the preference to a treatment with phosphates, such as would be given by filtration through a bed of broken coprolites or bone-ash, which would remove any tendency of the water to dissolve lead. To remove traces of lead from solution in water, treatment with carbonates or phosphates will suffice, a very convenient and efficient means being filtration through a medium containing calcium phosphate, such as animal charcoal.

A series of dyeing experiments were made on wool with a few of the brighter coal-tar colours, with a view of ascertaining the effect of small quantities of lead in the water used. The colouring matters taken were the following:—Naphthol yellow, Tartrazin, Manchester yellow, Brilliant green, Safranin, Magenta, Rhodamine, and Night blue. The only natural colouring matter experimented upon was indigo, which was dyed in the form of indigo sulphonic acid. Some of these colouring matters were dyed in a neutral bath, and others with addition of sulphuric acid. The experiments were made in series of four. In the first place, the water used was free from lead; in the second, $\frac{1}{2}$ grain of lead per gallon was added; in the third, $\frac{2}{3}$ grain; and in the fourth, 1 grain per gallon. It was observed that wherever sulphuric acid was used in dyeing, the colour was not affected by lead, but shades dyed in a neutral bath were rendered duller in proportion to the amount of lead present in solution. Wool treated neutral and with acid, without addition of colouring matter, behaved in a similar manner. In a neutral bath containing lead, the wool was dyed a drab shade, but with addition of a small quantity of sulphuric acid ($2\frac{1}{2}$ per cent. on the weight of the wool), it remained white. In the case of Rhodamine, one of the brightest of all colouring matters, 5 per cent. of alum was used in the dye-bath, and the shade was almost, but not entirely, unaffected by the presence of lead. In the case of Night blue, the colour was dissolved in acetic acid, but the shade was affected in a similar manner to those dyed neutral. It is true that the amount of acetic acid present in the dye-bath would be exceedingly small, and the effect of a larger amount was not tried. The saddening effect is apparently caused by the sulphur naturally present in the wool combining with the lead, and forming sulphide of lead. But the formation of sulphide of lead on the fibre does not take place in the presence of sulphuric acid.—G. H. B.

Bradford Water: its Hardness and Action on Lead. T. Whitaker. J. Soc. Dyers and Colourists, 5, 61—69.

THIS paper contains an extended series of observations on the small variations in the character of the Bradford water supply, both high and low level, with especial reference to its action on lead. The hardness is usually about 3 grains per gallon, a small part of which is temporary, and the total solids amount to about 7 grains. The analytical results are set forth in numerous tables from which certain conclusions may be drawn. The tendency of the water to act on lead becomes greater as the amount of hardness present (especially temporary hardness) becomes less. The action of the water on lead seems to depend on the quantity of acid in the water, and this may be derived from peat or may be carbonic acid, but its action is diminished when the hardness is increased. Pipes corroded by the action of one water will give up lead to a water which does not by itself act upon lead. So-called composition lead piping was found to greatly increase the tendency of the water to act on lead, and is therefore unsuitable for water supply. The influence of pressure was to slightly retard the action on lead, whilst heating the water to boiling immensely increased the rapidity of the action. Exposure to air and carbonic acid during contact with lead increases the action of the water. Numerous experiments showed that the lead in water is

partially or wholly removable by simple filtration through inactive media, such as filter-paper, asbestos, cotton wool, or crushed flints. As a measure to be taken up in the case of a water having a tendency to act on lead, the author recommends admixture with a harder water and a filtration through a bed of flints and limestone or sand.—G. H. B.

On the Peroxides of Cobalt and Nickel, and the Volumetric Determination of those Metals. A. Carnot. *Compt. Rend.* **108**, 610–612.

THE results of the author's experiments show that the brown oxide obtained when cobalt is precipitated by hydrogen peroxide and boiling potash, has exactly the composition of a sesquioxide, Co_2O_3 , and that the black oxide of nickel, precipitated by an alkaline hypochlorite, or bromine and potash, corresponds exactly to the formula of the sesquioxide of nickel, Ni_2O_3 . On the other hand, the almost black oxide of cobalt, obtained when a hypochlorite, bromine, or iodine, is used, always contains a notably larger proportion of oxygen than corresponds to the sesquioxide. Instead of Co_2O_3 , for example, the trials gave at least $\text{Co}_2\text{O}_{3.25}$ with hypochlorite, $\text{Co}_2\text{O}_{3.25}$ with bromine, and $\text{Co}_2\text{O}_{3.25}$ with iodine. The composition of the precipitate given by hypochlorite corresponds to the formula $2\text{Co}_2\text{O}_3 \cdot 4\text{Co}_2\text{O}_3$; and that given by bromine or iodine to $2\text{Co}_2\text{O}_3 \cdot 3\text{Co}_2\text{O}_3$. The bearing of these results upon analytical estimations of cobalt is obvious.—E. G. C.

Separation of Nickel and Cobalt after Oxidation in Ammoniacal Solution. A. Carnot. *Compt. Rend.* **108**, 741–744.

HYDROGEN peroxide, added before or after saturation with ammonia, gives at first a brown colour, passing into purple-red, rose, or violet, according to the relative quantities of cobalt and nickel present. Excess of caustic potash precipitates from this solution oxide of nickel, contaminated with a little cobalt; by repeating the treatment the oxide of nickel may be obtained pure; the alkaline filtrate containing the rosecobaltic salt, deposits on boiling the cobalt in the form of sesquioxide. The formation of the rose-coloured solution is a sure index to the presence of cobalt.

—J. M. H. M.

On the Limits of Error in Assays of Fine Gold. P. Charpentier. *Compt. Rend.* **108**, 612–613.

THE accuracy of determinations of gold, by either the fire or humid assay, can generally be guaranteed to about $\frac{3}{10,000}$ if the precautions usually insisted on are followed by the assayer. The author has made 300 experimental assays of chemically pure gold (0.5 grm. being taken in each case), with the object of finding how the results are affected by neglect or observance of any one, several, or all of these precautions. The conclusions arrived at are appended. The silver employed contained $\frac{24}{1,000}$ of copper.

1. The heat of the muffle should have a special intensity, but, if the assay be conducted at much too high a temperature, there is a *loss* of gold varying from $\frac{15}{10,000}$ to $\frac{35}{10,000}$; average $\frac{24}{10,000}$. 2. If the assay be conducted at too low a temperature there is an *excess* varying from $\frac{5}{10,000}$ to $\frac{8}{10,000}$; average, $\frac{6}{10,000}$. 3. Employing the maximum proportion of lead, viz., 17 grms., there is a *loss* of $0 - \frac{3}{10,000}$; average, $\frac{2}{10,000}$. 4. Using a minimum of lead, 0.5 grm., the *excess* is $\frac{4}{10,000}$ to $\frac{8}{10,000}$; average, $\frac{6}{10,000}$. 5. With a great excess of silver, 5 grms. instead of 1.5 grms., the assay falls to powder. *Excess* of $\frac{6}{10,000} - \frac{15}{10,000}$; average, $\frac{10}{10,000}$. 6. With only 0.5 grm. of silver, the *excess* can equal the weight of gold assayed. 7. The button, on its return to the furnace, should be carefully annealed. If all annealing and flattening

be omitted the assay falls to powder. There is a *loss* of gold varying from 0 to $\frac{25}{10,000}$; average, $\frac{8}{10,000}$. 8. If the first annealing be effected, on the contrary, at a maximum temperature of about 1,200°, there is a *loss* of gold of from 0 to $\frac{10}{10,000}$; average, $\frac{3}{10,000}$. 9. If flattening be omitted the errors vary between $\frac{10}{10,000}$ *excess*, and $\frac{7}{10,000}$ *loss*. 10. When the assays are beaten as flat as possible "parting" is difficult and violent; *excess*, varying from 0 to $\frac{10}{10,000}$; average, $\frac{6}{10,000}$. 11. If the second annealing (after flattening) be omitted, the plates are very lustrous, and there is an *excess* varying from $\frac{12}{10,000}$ to $\frac{37}{10,000}$; average, $\frac{25}{10,000}$. 12. The assay, having been flattened and annealed, is bent in the fingers into a coiled cornet; and the author recommends that the cornet should not be too closely coiled. If, on the contrary, the plate is bent into a very tight coil there will be an *excess*, ranging from 0 to $\frac{10}{10,000}$; average, $\frac{1}{10,000}$. 13. The cornet is treated first of all with nitric acid at 22° B. and then with acid at 32°. If acid at 22° be used for the three digestions, there is an *excess*, ranging from $\frac{10}{10,000}$ to $\frac{20}{10,000}$; average, $\frac{13}{10,000}$. 14. If, on the other hand, 32° acid is employed for all three digestions, the *excess* of gold varies from 0 to $\frac{5}{10,000}$; average, $\frac{2}{10,000}$.—E. G. C.

The Electrolytic Separation of Cadmium from Zinc. E. F. Smith and L. K. Frankel. *J. Franklin Inst.* **98**, 154–155.

THIS separation has been effected by Yoer, who used the acetates, and confirmed by Smith and Knerr, who found that the current must be carefully regulated to obtain good results. The separation can also be effected from the tartrates. In the new method, solutions of the double cyanides were employed, it having been ascertained that a feeble current would suffice for the complete deposition of each metal, when alone in a cyanide solution in presence of excess of an alkaline cyanide. The cadmium separates more readily and with a weaker current than is necessary for the zinc, the latter not being deposited until the excess of cyanide has been completely decomposed. The excess of cyanide is such that, with the strength of current employed, the decomposition of the alkaline cyanide does not take place in less than 48 hours; and as all the cadmium is deposited in 23 hours, the complete separation of cadmium from zinc is effected. The strength of the current used was such that it would deposit 3 cc. oxy-hydrogen gas per minute.—E. T.

Estimation of Silicon in Ferro-Silicon. A. Ziegler. *Chem. Zeit.* **13**, 562.

THE pulverised ferro-silicon is evaporated to dryness with aqua regia (1 vol. of nitric acid, 3 vols. of hydrochloric acid, and 4 vols. of water) on a water-bath, the residue evaporated to dryness with dilute sulphuric acid (1 to 3), and heated on sand-bath until sulphuric fumes are evolved. It is then treated with water on the water-bath, filtered, washed with water containing 1 per cent. of hydrochloric acid and ignited in a platinum crucible. If the silica retains any iron it is treated with aqueous hydrofluoric acid and by deducting the residue the amount of pure silica is found.

—D. A. L.

Arsenic in Glycerin. G. Vulpius. *Apoth. Zeit.* **4**, 389.

JANUS (*Chem. Zeit. Rep.* **12**, 293) showed that arsenic is contained in commercial glycerin. This has been more recently amply confirmed. The author states that the manager of a glycerin works informed him that to produce an article free from arsenic would necessitate an addition of 10 per cent. to current prices. To detect arsenic, 2 cc. of glycerin are mixed with 3 cc. of moderately strong hydrochloric

acid and a few pieces of metallic zinc are added. The gas which is evolved is allowed to act on filter-paper moistened with a 50 per cent. solution of silver nitrate. After 15 minutes the paper should show no yellow stains becoming black when moistened with water.—C. H. B.

Action of Phenols on Cinnamic Aldehyde. Probable Presence of the Latter in Woody Matter. A. Ihl. Chem. Zeit. 13, 560.

THE author has shown that cinnamon oil gives characteristic red colourations with phloroglucinol and resorcinol (this Journal 1889, 421) which he now finds is due to the cinnamic aldehyde in the oil, and, moreover, has obtained the following reactions with both cinnamic aldehyde and genuine cinnamon oil.

With cold alcoholic solutions in the presence of acid; deep dark red colouration with phloroglucinol; cinnabar red with resorcinol; full light red with oreinol; strong fleshy red with pyrogallol; and dirty red, on heating, with phenol, α -naphthol, and thymol. Dilute cinnamic aldehyde or the oil is coloured yellow by alcoholic aniline sulphate; and concentrated sulphuric acid colours them deep black. The phloroglucinol reaction is sufficiently delicate to serve as an indicator for the presence of traces of free acid. Phloroglucinol, resorcinol, oreinol, aniline sulphate, and sulphuric acid give similar reactions with lignin; cinnamic aldehyde is never suggested as a probable constituent of woody matter. Neither clove oil nor pimento oil are acted on in the cold by resorcinol or oreinol.—D. A. L.

Determination of Indigotin in Commercial Indigo. M. Hönig. Zeits. f. angew. Chem. 1889, 280—283.

THIS method is based on the fact that aniline and nitrobenzene in a boiling state are moderate solvents for indigotin. Under certain conditions it is possible to dissolve the indigotin completely, and it can be obtained in crystals from the solution. Other organic matters accompanying the indigotin in commercial indigo also go in solution, but they do not crystallise along with the indigotin. The process is carried out as follows:—0.5 to 0.8 gram. of the very finely powdered indigo is mixed with three times its volume of calcined sand, which has been deprived of fine dust, and the size of grain of which is 1 mm. The mixture is then treated in the modified Soxhlet apparatus, shown in the diagram. The extraction tube A contains a loose cotton

plug *a*, then a small layer of sand at *b*, then a mixture of sand and indigo at *c*, then again some sand, and finally a plug of cotton wool at *e*. The apparatus is then connected with a reversed condenser. The flask B is charged with about 50 cc. of aniline or nitrobenzene, perfectly free from water. The contents of the flask are gradually brought to a boil and a brisk ebullition is maintained, the vapours given off extracting the indigotin from the mixture. After 1½ to 2 hours the extraction will have proceeded so far that the liquor running from the extraction tube has only a pale blue colour. The extraction is now interrupted, and, after cooling the apparatus, the distilling flask is disconnected and the contents of the extraction tube washed two or three times with 95 per cent. alcohol. These washings are kept for further use. The extraction tube is emptied into a small dish, the mass spread with a spatula and dried in an air-bath at 105° to 110° C. for about half an hour or so. The mass is again filled into the extraction tube without loss, and, after putting the apparatus together, the extraction is continued for about 20 minutes, when it should be found that the liquor filtering through the extraction tube has no longer a bluish tint. The extraction is then complete: proof of this is found in the fact that the sand dried and calcined does not give off red-violet vapours. The solution in the distilling flask, usually coloured dark blue, is concentrated as much as possible. As a rule this can be done up to 15 or 10 cc. After cooling this residue, its volume is measured. It is then mixed with five or six times its volume of 95 per cent. alcohol—the previous alcoholic washings may be taken—filtered through a dried (at 110° C.) and weighed filter, and the crystals on the filter washed with 95 per cent. alcohol, until the washings have only a very pale blue colour. The filter is dried at 110° C. and weighed, thus obtaining the weight of the crystals of indigotin. To this weight is added that quantity which remained in solution in the mother-liquor, viz., for every 10 cc. of aniline, .013 gram. of indigotin; or for every 10 cc. of nitrobenzene, .021 gram. of indigotin. It makes no difference as regards the final result whether aniline or nitrobenzene be used as a solvent. In using the latter the crystals assume a better shape, and the corks are less attacked. It may be mentioned that it is desirable to estimate the ash in a portion of the indigotin obtained, in order to make sure that it is not adulterated with sand. The results of analyses given by the author show that the method gives very concordant results. The process is, of course, also applicable for the quick and convenient preparation of pure indigotin.—S. H.

Analysis of Cinchonas and Solubility of their Active Principles in Water, Alcohol, and Dilute Hydrochloric Acid. E. Landrin. Compt. Rend. 108, 750—753.

THE experiments were made on a sample of *C. succirubra* from the Dutch Government grounds at Java. The method of extraction followed by the author for some years is as follows: 300 grms. of the bark are powdered and passed through a No. 40 sieve, then mixed thoroughly with 1 litre of milk of soda-lime containing 75 grms. of quicklime and 75 grms. of solution of sodium hydrate at 40° B. To this mixture, thinned, if necessary, by a little water, 2 litres of petroleum spirit are added, heated to 100° for 20 minutes, with constant agitation; the oil is then decanted, and the extraction repeated with a second 2 litres. The first extraction yielded 11.45 grms. crystalline salts; the second, 1.71 grms. The 4 litres of extract are washed twice with 75 cc. of 10 per cent. sulphuric acid added to 150 cc. water; and a third time with one-third of these quantities. The acid extracts are boiled and neutralised with ammonia, and filtered, the last serving to wash the filter. On cooling, about nine-tenths of the alkaloidal sulphates crystallise out, are filtered off, and the mother-liquor precipitated by caustic soda, the alkaloids washed, dried, pressed, and transformed into sulphates by cautious addition of sulphuric acid, then added to the rest, and weighed; the sulphate of quinine is separated by known processes. Operating thus, the sample yielded per kilo.: total alkaloids, 75.92 grms.; crystallisable salts, 51.83 grms.; quinine sulphate, 21.27 grms.

The same sample, extracted respectively with boiling water, 90 per cent. alcohol, and dilute hydrochloric acid, as recommended by de Vrij, yielded the following results:—

One kilo. contained	Moisture.	Soluble. Insoluble		Total Alkaloids.		Crystallisable Salts.		Quinine Sulphate.	
				Soluble.	Insoluble.	Soluble.	Insoluble.	Soluble	Insoluble.
Treated with boiling water.....	100	340	160	61.42	11.50	43.49	8.34	15.85	5.42
" " 90 per cent. alcohol.....	100	325	575	65.97	9.95	45.71	6.12	18.27	3.00
" " dilute hydrochloric acid	100	260	640	58.68	17.24	39.61	12.22	13.88	7.39

The author prefers the extraction with hydrochloric acid. —J. M. H. M.

Examination of Commercial Olein for Linoleic Acid.

K. HAZURA. *Zeits. f. angew. Chem.* 1889, 283—284.

GRANVAL and VALSER lately drew attention to the fact, that olein of commerce is sometimes adulterated with linoleic acid (this Journal, 1889, 425). They also stated some tests for the presence of the latter. The author has found an analytical method, which is based on the following facts: (1.) Olein chiefly contains oleic acid, $C_{18}H_{34}O_2$, and small quantities of linoleic acid, $C_{18}H_{32}O_2$. On oxidising its alkaline solution with permanganate it gives solid products of oxidation, viz., the dihydroxystearic acid, $C_{18}H_{34}O_2(OH)_2$, which melts at $137^\circ C.$ and is nearly insoluble in water and ether; the tetrahydroxystearic acid, $C_{18}H_{32}O_2(OH)_4$, which melts at $174^\circ C.$ and is slightly soluble in water and insoluble in ether; and the azelaic acid, $C_9H_{16}O_4$, which is easily soluble in both water and ether. (2.) The linoleic acid contains small quantities of oleic acid, $C_{18}H_{34}O_2$, of linoleic acid, $C_{18}H_{32}O_2$, and isolinoleic acid, $C_{18}H_{30}O_2(OH)_2$. On oxidising an alkaline solution with permanganate solid products of oxidation are formed, viz., dihydroxystearic acid, tetrahydroxystearic acid, two hexahydroxystearic acids and azelaic acid.

The analytical process is as follows:—50 grms. of the olein to be tested are saponified on the water-bath with dilute alcoholic potassium hydrate. The potash soap is freed from alcohol and dissolved in 1,000 cc. of water. This strong alkaline solution is gradually mixed with 1,000 cc. of a 5 per cent. solution of potassium permanganate. After $\frac{1}{2}$ —1 hour the manganese peroxide is filtered off, the filtrate acidified with sulphuric acid and again filtered. The filtrate thus obtained is neutralised with potassium hydrate, concentrated to about 300 cc., and again acidified with sulphuric acid, which produces a precipitate. The acid liquid and the precipitate are shaken with ether. If the precipitate dissolves in ether, it consisted of pure azelaic acid and the original olein is free from linoleic acid. If the precipitate does not dissolve in ether, it is probably owing to the presence of linoleic acid. To be quite certain, the precipitate is filtered several times, recrystallised from water or alcohol with the addition of animal charcoal, and after air-drying its melting point is determined. If the latter be above $160^\circ C.$, linoleic acid is undoubtedly present.—S. H.

Lard and Lard Adulterations. H. W. WILEY. U.S. Dept. of Agriculture Bulletin, 13, Part 4.

A. The pamphlet first describes the different kinds of lard and the various materials used in adulterating it.

1. LARD.—The followings kinds are recognised. (a.) *Neutral lard* made from the leaf of the freshly slaughtered hog, chilled, ground, and kettle-rendered. It contains at most 0.25 per cent. of free fatty acid, and is used almost wholly for making butter substitutes. (b.) *Leaf lard* obtained from the residue from neutral lard by rendering it by means of steam under pressure. (c.) *Choice kettle-rendered lard* obtained from such portion of the leaf not needed for margarin together with the fat from the back, by rendering in steam-jacketed open kettles. (d.) *Prime steam lard* from the whole of the head (after removal of the jaw), the fat attached to the intestines and heart, and fat from the back, and leaf when not otherwise required.

(e.) *Butchers' lard* from the accumulated scraps of these tradesmen. It is usually kettle-rendered.

2. STEARINS. By this term is meant the more solid part of any fat from which the more fluid portion has been removed by pressure. Such are: (a.) *Lard stearin* made from "prime steam lard" by treatment in screw presses at 50° — $60^\circ F.$ The expressed *lard oil* is used for burning and lubricating; it contains less free fatty acid than the solid residue, the quantity in which amounts to 0.5 per cent. The stearin is worth more than the lard. (b.) *Oleo-stearin* obtained from the caul fat of hives rendered in open kettles at a low temperature. The resulting tallow is kept at 80° — $90^\circ F.$ for 36—48 hours, and pressed at $90^\circ F.$; the *aleo-oil* is used in margarin manufacture.

3. COTTON-SEED OIL.—Cotton seed is screened and then freed from any remaining lint by being put through a gin; about 20 lb. per ton are obtained. The clean seed is cut up, and the hulls removed by sieving; it is then ground to meal, heated to 210° — $215^\circ F.$, made into cakes weighing about 16 lb. each, and subjected to a pressure of 3,000—4,000 lb. per square inch. (For the yield, see this Journal, 1889, 431.) The expressed cakes contain about 10 per cent. of oil, and are used for cattle food or as a fertiliser. The crude oil contains about 1.5 per cent. of free fatty acid. The manufacture is chiefly conducted in winter, the seed not keeping well in summer. The crude oil is shipped in bulk. It is refined by means of caustic soda (compare this Journal, 1888, 756); the oil thus obtained after being heated and clarified is termed *summer yellow oil*, and if cooled, and the stearin removed, *winter yellow oil*. The cotton-oil stearin is used for making butterine and soap. The yellow oil agitated with fuller's earth and filtered, becomes colourless, and is known as *white oil*.

B. Properties of lard and its adulterants.

1. PURE LARD. (a.) *Specific gravity* is about 0.890 at $40^\circ C.$ and 0.860 at $100^\circ C.$ referred to water at $4^\circ C.$ (b.) *Melting point* varies from $35.1^\circ C.$ (from the foot) to $44^\circ C.$ (intestinal fat). Average value $37^\circ C.$ (c.) *Solidifying point of fatty acids* determined by Dalcian's method varies from 32.1° to $42.7^\circ C.$ (Compare this Journal, 1889, 423—424.) (d.) *Melting point of fatty acids* ranges from 36.9° and $46.6^\circ C.$ (e.) *Refractive index* corrected to $25^\circ C.$, averages 1.4620. (f.) *Colour reactions* with litmus and sulphuric acids are usually slight, and though not serving as an absolute criterion, are of value in discriminating between pure and sophisticated samples. The variations observed in the case of pure lards are probably due to the different quantities of gelatinous and similar matter entangled in different samples. (g.) *Rise of temperature with sulphuric acid*. The extreme values obtained were 37.1° and $46.2^\circ C.$ The author is engaged in endeavouring to measure the heat evolved in this reaction instead of the temperature. (h.) *Volatile fatty acids*. The quantity from 5 grms. of the fat neutralised 0.2 to 0.4 cc. of decinormal alkali. (i.) *Insoluble fatty acids* ranged from 93 to 95 per cent. (l.) *Free fatty acids* rarely exceeded 0.5 per cent. (m.) *Saponification equivalent* varied between 272 and 294, and averaged 280. (n.) *Iodine number* varied according to the part of the animal from which the lard had been obtained. Thus it was 57.34 for intestinal lard, 52.55 for leaf lard, 77.28

for foot lard, 85.03 from head lard. The average value for pure lard with miscellaneous origin was 62.48. (a.) *Reaction with silver nitrate.* Using either Beechi's or Milliau's prescription, the reduction or colouration was extremely small or nil. (p.) *Microscopic appearances.* A definite crystalline structure is perceptible, but the character of the crystals is not distinguishable; if slowly crystallised from ether, rhombic crystals of stearin are obtained, differing from the fan-shaped crystals yielded by beef or mutton fat under like conditions. (q.) *Moisture* varies from a trace up to 0.7 per cent.

2. COTTON-SEED OIL. — (a.) *Specific Gravity.* The following table shows the specific gravity of normal oil at various temperatures referred to water at 15° C. as unity:—

Temperature. °C.	Specific Gravity.	Temperature. °C.	Specific Gravity.
10	*9249	26	*9149
11	*9243	27	*9143
12	*9237	28	*9136
13	*9231	29	*9129
14	*9224	30	*9123
15	*9218	31	*9117
16	*9212	32	*9110
17	*9206	33	*9105
18	*9199	34	*9098
19	*9193	35	*9092
20	*9187	36	*9086
21	*9181	37	*9079
22	*9174	38	*9073
23	*9168	39	*9067
24	*9161	40	*9060
25	*9155	50	*8997

(b.) *Melting point.* Near or below 0° C. (c.) *Solidifying point of fatty acids* by Dalcian's method ranged from 30.5° to 35.6° C., mean, 33.5° C. (d.) *Melting point of fatty acids.* Maximum, 44.4° C.; minimum, 34.6° C.; mean, 39.1° C. (e.) *Refractive index* averaged 1.4674 at 25° C.; its mean rate of variation for each degree centigrade was .000288—sensibly the same as that of lard. (f.) *Colour reactions* with nitric and sulphuric acids are marked and fairly characteristic. (g.) *Rise of temperature with sulphuric acid.* Maximum, 90.2° C.; minimum, 80.1° C.; mean, 85.1° C. (h.) *Volatile fatty acids.* The quantity from 5 grms. of the oil neutralised at most 0.5 cc. deci-normal alkali. (k.) *Saponification equivalent* was not very constant; the mean was 283.8. (l.) *Iodine number* ranged between 100 and 116.97; the mean value was 109.02. (m.) *Reaction with silver nitrate.* The reducing action of cotton-seed oil on silver nitrate, when tested according to Beechi or Milliau, is well marked and of great analytical importance.

3. STEARINS. — (a.) *Specific gravity* differed little from that of lard. (b.) *Melting point* varied according to the origin of the stearin; thus a lard stearin from a dead (as opposed to slaughtered) hog melted at 38.2° C., a prime lard stearin at 44.3° C., and two oleo-stearins at 51.9° and 53.8° C. respectively. (c.) *Refractive index* appears to be slightly higher than that of the glycerides from which any given sample is derived. (d.) *Colour reactions* are similar to those of the parent glycerides. (e.) *Rise of temperature with sulphuric acid* is difficult to determine in a manner strictly comparable with that applicable to the original glycerides on account of the high initial temperature required. The values, however, appear to be similar to those given by the latter. (f.) *Volatile fatty acids* occur in negligibly small quantity. (g.) *Saponification equivalent* is practically the same as that given by the original glycerides. (h.) *Iodine number* is lower than that of the original glycerides; e.g., two oleo-stearins gave the numbers 17.38 and 26.81; three lard stearins, 44.24, 44.24, and 49.78; various cotton-seed stearins gave results varying between 85.28 and 99.39. (i.) *Reaction with silver nitrate.* This takes place in a manner quite comparable with that of the original glycerides; it is somewhat less marked, however, with cotton-seed stearin than with cotton-seed oil. (l.) *Microscopic appearances.* Lard stearins give crystals like those mentioned under "lard;" oleo-stearin gives characteristic fan-shaped crystals. (m.) *Moisture* is generally only present in traces.

4. ADULTERATED LARD. — (a.) *Specific gravity* does not necessarily differ from that of pure lard, though cotton-seed oil, if present in greater quantity than 15 per cent., raises it above normal limits. It generally ranges from 0.906 to 0.910 at 35° C., compared with water at the same temperature. (b.) *Melting point* is no certain guide. Of factitious lard from Fairbank and Co. the highest was 41.9° C., the lowest 31.3° C., the mean 38.1° C., while the samples from Armour and Co. gave 43.3°, 38.9°, and 40.6° C. for corresponding figures. (c.) *Solidifying point of fatty acids.* Fairbank's, mean, 37.4° C.; Armour's, mean, 39.8° C. (d.) *Melting point of fatty acids.* Fairbank's, mean, 40.6° C.; Armour's, mean, 42.8° C. (e.) *Refractive index.* Fairbank's, mean, 1.4651; Armour's, mean, 1.4634. (f.) *Colour reactions* are usually strongly indicative of cotton-seed oil. A pinkish tint is sometimes yielded by lards containing much beef-fat stearin, though it cannot with certainty be said to be due to that substance. (g.) *Rise of temperature with sulphuric acid*—

Fairbank's, maximum, 68.8° C., minimum, 51.3° C.
Armour's, " 58.9° C., " 42.1° C.

(h.) *Volatile fatty acids* negligibly small. (k.) *Saponification equivalent.* Fairbank's, mean, 279.4; Armour's, mean, 275. (l.) *Iodine number*—

Fairbank's, maximum, 94.78, minimum, 78.24.
Armour's, " 71.19, " 54.11.

(m.) *Reaction with silver nitrate.* Unless the proportion of cotton-seed oil in a lard be very small, reduction of silver sufficient for its detection always occurs. (n.) *Microscopic appearances.* Tufted crystals of the stearins used as adulterants are perceptible, as well as normal lard crystals. (o.) *Moisture* is generally present only in traces, but 30 per cent. was found on one occasion; it is not a common adulterant.

The following table shows the mean results of the analytical data obtained during this investigation:—

Kind of Samples.	Specific Gravity.	Sapon. Equiv.	M. P.	M. P. of Fatty Acids.	S. P. of Fatty Acids.	Maumene's Test.	I. Number.	Refractory Index.

Methods of Analysis Employed.

1. Specific Gravity.—The specific gravity bottle and the Westphal balance were used for oils and fats in the liquid condition, and a platinum crucible, of known displacement, weighed, together with the fat, in air and water, for fats in the solid state.

In the following tables, which are compiled from the data obtained by C. A. Crampton, the specific gravity is always referred to that of water at 4° C., except where otherwise stated.

2. Melting Point.—It is not easy to fix the precise melting point of a fat, but the best way to do so is to observe the temperature at which a thin disc floating in a medium of its own density assumes the form of a sphere. The apparatus shown in the figure achieves this object.

The inner test tube is 30 cm. long and 3·5 cm. in diameter; the outer beaker 35 × 10 cm. The tube is about half filled with boiling distilled water; on this, while still hot, is poured alcohol which has also been boiled. The beaker contains water, which can be agitated by any suitable means, such as a stream of air from the little hand-blower shown in the figure. An ordinary thermometer gives the temperature of the liquid in the beaker, while an accurate one, reading to 0·1° C., is suspended in the test tube. The whole apparatus having been cooled to about 10° C., discs of the fat to be examined are prepared by allowing it to fall from a dropping tube from a height of 15—20 cm. on to a smooth piece of ice floating in water, and are transferred to the inner tube by means of a spatula. They sink through the alcohol until they come to a stratum of alcohol and water of their own specific gravity, and remain floating there. The temperature of the bath is now slowly raised until the discs become sensibly spherical, when the temperature indicated by the inner thermometer, placed as close as possible to the

fat globule and gently rotated during the last stages of fusion, is read off. The inner tube can then be removed and another substituted for a fresh determination. After cooling, the fat globules can be picked out with a small spoon at the end of a wire, without disturbing the layers of water and alcohol, and the tube used again. It is necessary to renew its contents after three or four days, as it absorbs air, and this escaping in bubbles on heating, buoys up the disc of fat and brings it to the top, thus spoiling the determination.

3. Refractive Index.—This was determined by an apparatus described by Abbe in his brochure "Neue Apparate zur Bestimmung des Brechungs- und Zerstreuungsvermögens fester und flüssiger Körper." For the higher temperatures the hot room of a Turkish bath proved useful. The following table shows some results corrected to the uniform temperature of 25° C.:

4. Rise of Temperature with Sulphuric Acid.—The apparatus used is based on that employed by W. Ramsay for the determination of the molecular weights of nitrogen trioxide and tetroxide by Raoult's method (J. Chem. Soc. Trans., 1888, 622). The functions of its parts are obvious from the figure; when in use its lower portion is covered by

a non-conducting case. The quantities of fat or oil and sulphuric acid taken are those generally adopted, viz., 50 cc. and 10 cc. respectively. It was found that a difference of 10° in the starting temperature made one of 2°—3° in the rise observed.

5. Solidifying Point of Fatty Acids.—A tube 15 cm. by 2.5—3 cm. is filled with the fused fatty acids, a thermometer graduated to 0.1° C. inserted in it, and the whole protected from draughts by being placed in an empty bottle, the bottom of which has been warmed so as to avoid chilling the fatty acids prematurely. When crystallisation commences the temperature begins to rise, at which point the thermometer should be stirred round the tube in both directions three or four times; this hastens the crystallisation, and the temperature continues to rise and finally remains stationary for one or two minutes. This is taken as the true solidifying point.

6. Melting Point of Fatty Acids.—The capillary method or the plan of heating a film of the fatty acids on the bulb of a thermometer, held in the centre of an empty flask until it is collected into a single drop, was used with success.

7. Colour Reactions (with sulphuric and nitric acids).—These call for no comment.

8. Microscopic Examination.—The method adopted was to dissolve 2—5 grms. of the fat in 10—20 cc. of ether in a test tube and allow it to stand loosely plugged with cotton-wool all night. The crystals deposited at the bottom of the tube were then examined under $\frac{1}{2}$ or $\frac{1}{4}$ in. obj. The different forms observed are shown in a series of 20 photomicrographs, for which the original pamphlet must be consulted. The method proved of value for the detection of beef fat, 20 per cent. of which could be readily discerned, though with 10 per cent. the indications were somewhat doubtful.

9. Soluble and Volatile and Insoluble Fatty Acids, and Saponification Equivalent.—The determination of these calls for no remark, save that it was found convenient in weighing out quantities of fats that were required to approximately equal some round number of grams (e.g. 5 grms.), to use a pipette of such capacity that it held that weight of fat at a temperature somewhat above its melting point.

10. Iodine Number.—This was determined in the usual manner. The author comments on the large fluctuations in the strength of the iodine solution observed. A solution allowed to stand from April 23rd, 1888, to November 10th, 1888, consumed, for 10 cc., 17.9 cc. on the first date and only 7.3 cc. on the second.

11. Reaction with Silver Nitrate.—Two forms of the Beech prescription were employed. (i.) 10 cc. of a solution containing $\frac{1}{10}$ — $\frac{1}{100}$ gm. of AgNO_3 in 200 cc. of 95 per cent. alcohol and 20 cc. of ether, together with 10 cc. of a mixture of 15 parts of rape oil and 85 parts of amyl alcohol. (ii.) 1 cc. of a solution containing 1 gm. of AgNO_3 in 200 cc. of a mixture of equal parts of alcohol and ether, together with 10 cc. of the amyl alcohol mixture mentioned under (i.).

The second solution acts more promptly than the first, which is nevertheless otherwise more satisfactory. The method of applying the test is the same in both cases, and consists in mixing the requisite quantities of the reagents with 10 cc. of the oil in a test tube, shaking well, and pouring into a porcelain dish on a steam-bath. Heating and occasional stirring are continued for 20 minutes. Results:—(a.) With pure cotton-seed oil. In from two to three minutes the mixture turns red; in five to ten minutes it becomes so brown as to appear black in thick layers; at the end of the test metallic silver is deposited on the sides of the dish, varying in colour from bluish black to reddish purple. In the liquid float particles of silver, giving it a greenish tint. (b.) With lard containing more than 20 per cent. of cotton-seed oil. The same phenomena occur but less promptly. (c.) With quite small percentages of cotton-seed oil. The reaction eventually appears. (d.) Animal fats, rape, olive, peanut and linseed oils, give either no colour or at most a faint pink.

Some Peculiar Reactions.—Crude cotton-seed oil gives a less sharp reaction than the refined oil. Linseed oil gives a reddish colour but no reduction. Head and gut lard give a slightly greater colouration than leaf lard. It remains to be seen whether lard made from swine fattened on beech-mast or cotton-meal would give the reaction. A trace of alkali in the oil to be tested (such as might come from an imperfectly washed cotton-seed oil) might precipitate silver oxide and obscure the reaction; to avoid this it is well to make the solution of silver nitrate distinctly acid with nitric acid. It has been suggested that the substance present in cotton-seed oil causing the reaction is an aldehyde; in any case it appears to resist saponification, for Millian's modification of the Beechi's test is founded on the use of the fatty acids instead of the original oil. There is little doubt that no commercially profitable adulteration with cotton-seed oil could fail to be detected by this test.

Millian's Process.—This was modified by the author by the use of a round bottomed porcelain dish holding about 50 cc. in place of the tube generally employed, and by the acidification of the silver nitrate solution with 0.5 to 1.0 cc. of pure nitric acid.

It was found that the reaction when it *did* occur was remarkably sharp, but in certain cases it failed to appear altogether; it also appeared that the fatty acids, if kept, lost their reducing power.

12. Sulphur Chloride Test.—This seemed likely to be of use, but time for its full investigation failed.

Quantitative Determination of Adulterants in Lard.

From the results got by the processes mentioned above some idea may be obtained of the percentage of adulterants present. It by no means follows that calculations based on

different data yielded by the sample under examination will yield identical results. Aid may be had by remembering that cotton-seed oil and stearin are usually present in "compound lards" in the proportion of 1:5:1. The following table is based on this assumption.

Observed Sp. Gr. at 35° C.	Pure Lard.	Adulterant.	Of which there is —	
			Cotton Oil.	Stearin.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
0950	10.0	0.0	0.0	0.0
0955	87.5	12.5	7.5	5.0
0960	75.0	25.0	15.0	10.0
0965	62.5	37.5	22.5	15.0
0970	50.0	50.0	30.0	20.0
0980	25.0	75.0	45.0	30.0
0985	12.5	87.5	52.5	35.0
0990	0.0	100.0	60.0	40.0

The index of refraction is perhaps as good a single gauge of the percentage of adulterant as any.

From the methods already worked out as applied to the two classes of "compound lards" examined, the following general results are deducible:—

Method of Examination.	Sample from—	Per Cent. of Adulteration.

The foregoing table is compiled from the very voluminous tables embodied in the pamphlet. The samples recorded have been selected either because they display some peculiarity or else fairly represent the average of a large number of analyses.

The rest of the pamphlet is occupied with abstracts from recent numbers of the *Analyst* of the methods used by various chemists for the detection of adulterants in lard, and by the reports of sundry legal cases turning upon the alleged adulteration of samples of lard.

In conclusion, the author clearly points out the gross fraud practised by selling the so-called "refined lard" as genuine lard, and records with satisfaction the fact that the largest American manufacturers of factitious lard have abandoned the use of the word "refined" and are selling the product as "compound lard."

Scattered through the pamphlet are several statements of interest which do not fall into the divisions under which the rest of it has been abstracted for this Journal. Such are:

(1.) *Definition of the "guts" of a hog.*—As used by the hog-packers, this term means the whole abdominal viscera. Of these, everything except the liver and the intestines

proper (which are used for sausage casings) goes into the rendering tank. It is stated that the grease thus obtained is used for the manufacture of lard oil, and soap, and does not enter into the lard of commerce. (2.) *White grease* is chiefly made from hogs which die in transit, and until lately from hogs dead from disease. (3.) *Brown grease* is made from the intestines of the animals mentioned under (2). (4.) *Yellow grease* is made by the packers from any refuse they may have, as well as from any hogs that may die on their hands. (5.) *Pig's-foot grease* is chiefly obtained from the glue factories. All these varieties are chiefly used for making lard oil and soap. (6.) Now-a-days all beef fat is not termed *tallow*, but is divided into several sorts, such as "butter-stock" rendered from the caul fat at a low temperature (and from which is manufactured by pressure oleo-oil and oleo-stearin), kidney-fat (suet), marrow-stock, and tallow, the last being made from the trimmings and portions of the viscera. (7.) *Other adulterants of lard* are said to be dead-hog grease and stearin, pea-nut and other vegetable oils. Such practices seem never to have been in use on a scale of commercial importance. (8.) The appended table gives the analytical results of some miscellaneous oils examined in the course of this investigation:—

* Gelatinous precipitate formed consisting apparently of the silver salt of an organic acid.

(9.) *Statistics of the lard industry.*—The annual production of lard in the United States is about 600,000,000 lb., of which about half is pure and half "compound" lard. The exports amount to 320,000,000 lb., and of this about 40 per cent. is "compound" lard. The total quantity of cotton-seed oil accounted for in this way is 120,000,000 lb.

In 1882 it was estimated that the oil industry was represented by the following data:—

" 110,000 tons of seed yielding 35 galls. of crude oil to the ton, amounting to 14,350,000 galls. worth 30 cents per gall.	Dols.	4,305,000
" 110,000 tons of seed yielding 22 lb. cotton lint to the ton, amounting to 9,029,000 lb. cotton, worth 8 cents per lb.		721,600
" 110,000 tons of seed yielding 750 lb. of oil cake to the ton, amounting to 137,277 tons, at 20 dols. per ton.		2,745,549
		7,772,149
Deduct the price of the seed, reckoning it to be 10 dols. per ton.....		4,100,000
Gross profit		3,672,149

—(Brant. *Vegetable and Animal Oils.*)

The crude oil is said to have a specific gravity of ·9306 at 59° F., and the refined oil one of ·9264 at the same temperature. (Compare this Journal 1889, 431.) By cooling the refined oil, palmitin is removed, its specific gravity lowered, and it becomes more suited for the adulteration of olive oil."—B. B.

Dyewoods and Extracts; their Use and Abuse. L. Bruehl. Textile Colourist, 1889, No. 114 et seq.

See under VI., pp. 612—618.

Estimation of Raffinose in Raw Sugar. T. Breyer. Chem. Zeit. 13, 559—560.

The inversion is conducted in the following manner:—50 cc. of the polarisation solution (26·048 grms. per 100 cc.) are poured into a "50—55 cc. flask" and acidified with 5 cc. of hydrochloric acid (sp. gr. 1·182). The flask is then placed in a water-bath, and heated to about 70°, simultaneously with

a similar flask filled with water and with a thermometer in it. The heat is regulated so that this thermometer registers 68—69° for five minutes, five minutes being allowed for it to reach this temperature. When the inversion is complete, the solution is quickly cooled, and allowed to stand for some hours in the room where it is to be polarised. After accurately filling to the mark, and if necessary decolourising with dry washed animal charcoal, the solution is filtered into a covered cylinder and polarised in a glass tube with wide tube attached for the thermometer. From the polarisation before and after inversion, and the thermometer reading, the apparent amount of cane-sugar can be calculated by Clerget's formula. A difference of 0.5 or over from the direct polarisation may be regarded as indicating the presence of other optically active substances, and in the absence of substances capable of reducing Fehling's solution, the true amount of cane-sugar may be calculated by the following formula, which is a combination of Clerget's and Creydt's formulae. The difference between the number so found and the direct polarisation may be assumed to be due to a definite quantity of raffinose, which may be calculated:—

	Saccharose.	Raffinose.
A. Direct polarisation.....	+ 100	+ 100
B. Polarisation after inversion, at t	$-(11 - \frac{t}{2})$	+ 5.7; or corrected for temperature:— $+ (16.7 + \frac{t}{5})$.
C. Difference for 1 original polarisation.....	$100 + 11 - \frac{t}{2}$ 100	0.194; or corrected for temperature:— $+ (109 - 16.7 - \frac{t}{5})$. 100

S. Percentage of sugar.

R. Percentage of raffinose.

1. $A = S + 1.85 R$.

2. $C = \frac{100 + 11 - \frac{t}{2}}{100} S + 1.85 R \times 0.493$.

3. $0.493 A = 0.493 S + 1.85 R \times 0.493$.

By subtracting 3 from 2

$S = C - 0.493 A$

$$\frac{111 - \frac{t}{2}}{100}$$

$$R = \frac{A - S}{1.85}$$

It is shown that neither differences in concentration nor in temperature, within certain limits, will affect Creydt's constants for the inversion of raffinose solutions; in fact the concentration is neglected in Creydt's formula, and as regards temperature, the variations in rotary power of the products of the inversion of raffinose (levulose and dextro-rotary galactose and perhaps dextrose) are found to practically neutralise one another, and therefore the above formula may be depended on under ordinary circumstances; but if a correction be required it is simply necessary to substitute the expression—

$$\left(\frac{100 - 16.7 - \frac{t}{5}}{100} \right) = \frac{53.3 - \frac{t}{5}}{100}$$

for the number 0.493 used in the above equations, and then—

$$S = \frac{100 C - \left(\frac{53.3 - \frac{t}{5}}{100} \right) A}{100.7 - 0.493 t}$$

—D. A. L.

PATENTS.

Improvements in or relating to Oil-Testing Machines.
W. S. Boulton, Birkenhead. Eng. Pat. 10,883, July 27, 1888. *Ed.*

The apparatus consists of an expanding journal B fixed on the shaft D, and made in two halves kept separate by the

spring C, but adjustable towards each other by the screws M. The journal works in a metal bush A provided with a flange and surrounded by a jacket E. The jacket is furnished with a thermometer G.

Fig. 1.

Fig. 2.

J is a burner for heating the jacket E. The amount of oil to be applied to the journal is measured by the narrow bore tube R, from which the oil is delivered by the plunger S (Fig. 4). The amount of friction between the journal B and the bush A corresponds to the deflection of the

Fig. 3.

Fig. 4.

pendulum J, which is connected by means of a chain with the arm *c* fixed to the jacket E. The amount of deflection of the pendulum is shown by the pointer K' on the dial K.

An Improved Funnel for Facilitating the Introduction of Liquids into Bottles, Jars, and other Vessels. T. C. Howlercroft, Uttoxeter. Eng. Pat. 7789, May 9, 1889. 6d.

A FUNNEL of the ordinary form is caused to fit air-tight into the neck of a bottle by means of a conical-shaped

collar or band of some elastic material round the lower portion of the stem. Above the collar is a tap to control the flow of the liquid. An air-tube is fixed on the outside of the funnel, and carried down to the top of the elastic collar, and through the stem to the end, that portion of it and the stem below the collar being perforated for the passage of air from the bottle. The advantages are:—(1.) The prevention of the sudden overflow of the liquid from the bottle, owing to the air having a means of escape. (2.) The exact amount of liquid required can be introduced. (3.) When the bottle is quite filled, if the tap be turned, the pressure of the external air will prevent the escape of the fluid from the stem on withdrawing the funnel. A drawing is attached to the specification.—E. S.

DIE TECHNIK DER ROSANILINFARBSTOFFE. ENTWICKELUNGSGESCHICHTLICH DARGESTELLT UND FÜR PRAXIS UND WISSENSCHAFT BEARBEITET. DR. OTTO VON MÜHLHAÜSER. Stuttgart, 1889: Verlag der J. G. Cotta'schen Buchhandlung Nachfolger. London: H. Grevel & Co., 33, Covent Garden.

LARGE 8vo volume, strongly bound in cloth, price 1*l.* 4*s.* The work contains Preface, Table of Contents, 283 pages of subject-matter, copious alphabetical index, glossary of abbreviated titles of literary works of reference, 10 sheets of admirably executed engravings illustrative of descriptions in the text, and 5 pages of classified descriptions of the parts lettered in the sheets of engravings. The text is divided into a GENERAL PART and a SPECIAL PART. The former is subdivided as follows:—

PRODUCTION OF THE ROSANILINES.—Construction of the Rosanilines from 1 mol. of a non-phenylated C_1 -compound and 3 mols. of an aromatic base. Construction of the Rosanilines from $\frac{1}{2}$ mol. of a mono-phenylated C_1 -compound and 2 mols. of an aromatic base. Construction of the Rosanilines from 1 mol. of a C_1 substituted aniline substituted at the nitrogen, and 2 mols. of an aromatic base. Construction of the Rosanilines from 1 mol. of an *N*-benzylated amine and 1 mol. of an aromatic base. Construction of the Rosanilines from 1 mol. of a diphenylated C_1 -compound and 1 mol. of an aromatic base. Preparation of Rosanilines from triphenylmethane derivatives by alterations in the substituted groups.

FURTHER PREPARATIONS FROM THE ROSANILINES.

CONVERSION OF THE COLOURING MATTERS INTO LEUCO BASES.—Production of Leuco bases. Further preparations from the Leuco bases. Conversion of poly-amidized triphenylmethanes into colouring matters.

SPECIAL PART.—Diamidotriphenyl carbinols. Derivatives of diamidotriphenyl carbinol. Triamidotriphenyl carbinols. Triamidotolylidiphenyl carbinols. Triamidoditolylphenyl carbinols.

HIGHER HOMOLOGUES.—Diamido-naphthylidiphenyl carbinols. Triamido-naphthylidiphenyl carbinols.

THE DYEING OF TEXTILE FABRICS. By J. J. HUMMELL, F.C.S., Professor and Director of the Dyeing Department of the Yorkshire College, Leeds. Third edition. Cassell & Co., Limited, London, Paris, New York, and Melbourne. 1888.

THIS important work now appears as a third edition, and in a slightly enlarged form. The text, illustrated with 97 diagrams, covers 527 pages, exclusive of preface, table of contents, and list of illustrations. The price is 5*s.* It has been sufficiently esteemed in Germany to render it advisable to issue a German edition, which is greatly appreciated. The form of the work is, apart from the enlargement, precisely like that of preceding editions.

Trade Report.

(From Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Change in Excise Duty on Matches.

A despatch, dated the 4th July last, has been received at the Foreign Office from Mr. Audley C. Gosling, Her Majesty's Chargé d'Affaires at St. Petersburg, transmitting an extract from the *Journal de St. Pétersbourg*, notifying a change in the Russian excise duty on matches of home and foreign manufacture, which was imposed in May 1888. The change is as follows:—

The excise on matches of home manufacture is one-half copeck per box of from 75 to 150 matches, and of three-fourths of a copeck per box of from 150 to 225 matches.

The excise on matches of foreign manufacture is one copeck (credit) per box of from 75 to 150 matches, and one copeck and a half (credit) per box of from 150 to 225 matches.

Matches exported to the Asiatic markets are not free from payment of excise.

Imposition of Transit Duty on Goods passing through Batoum.

A despatch, dated the 26th July last, has been received at the Foreign Office from Mr. A. Gosling, Her Majesty's Chargé d'Affaires at St. Petersburg, enclosing an extract from the *Journal de St. Pétersbourg* for the same date, according to which the Imperial Council, with the approval of the Emperor, has decided that for 10 years a transit duty will be levied on all goods passing through the port of Batoum. This duty will be:—

1. One-half copeck per pound on wood for building purposes (with the exception of cachou, walnut, carob, and palm), on firewood, salt, cement, common stones, mineral coal, and raw naphtha; and

2. One copeck per pound on all other articles.

This duty will be levied without examining the goods in detail and according to the quantity indicated on the documents accompanying the goods.

PORTUGAL.

Abolition of Export Duties on Wine.

A despatch, dated the 16th July last, has been received from Mr. G. G. Petre, Her Majesty's Minister at Lisbon, enclosing copies and translation of a law passed by the Cortes at the close of the last session, abolishing the export duties on wines levied in Portugal. The following is a copy of the translation in question:—

Art. 1. The exportation of common wines, whether white or red, is free from duty, but nevertheless red wines will be liable to a statistical duty of 2 reis (0.106*d.*) per decalitre, and white wines to that of 1 real (0.053*d.*) per decalitre.

Art. 2. The duties levied in the Portuguese colonies on the importation of wine or vinegar produced in and sent from the continental part of the kingdom and from the islands are abolished.

Art. 3. The octroi duty in Lisbon on charcoal is reduced to 8 per cent. *ad valorem*, and coke must pay the same rate of duty.

Art. 4. The duties imposed in virtue of the law of July 13, 1888, on brandy and alcohol, shall be raised as follows in the respective articles of the General Customs' Tariff. "Article 217," brandy and alcohol in casks or demijohns, per decalitre of pure alcohol, reis 1,800 (8*s.*) "Article 218," brandy and alcohol in bottles or flasks or the like, and alcoholic beverages not otherwise specified, per decalitre of liquid, reis 2,200 (9*s.* 9.33*d.*).

§. In order to aid the several bodies and individuals referred to in this article in the making of these wines, the Government will engage abroad the duly qualified technical "personnel" that may be required, with a view to their carrying out in the private wine-lodges in the most important wine-growing regions and at the proper seasons the various wine-making operations that may be called for.

Art. 6. Any distilleries set up for the purpose of making fine brandies, like French cognac, or any fine brandies, exclusively out of Portuguese wines, will be exempted during five years from the payment of any direct taxes.

§. The fixed price of 33.3 reis (1.77*d.*) per kilogramme of sulphuret of carbon as at present paid by the wine-growers is guaranteed to them, irrespective of the price at which the Government may be able to buy it.

UNITED STATES.

Customs Decision.

Certain so-called calcined magnesite, having all the characteristic properties of a cement, and destined for use as a mortar in cementing magnesite bricks, is dutiable as cement at the rate of 20 per cent. *ad valorem*.

URUGUAY.

Changes in Customs Tariff.

Note.—Kilog. = 2.204 lb. avoird. Peso Fuerte = 4*s.* 2*d.*

The Uruguayan Government has recently passed a law altering the rates of Customs duty leviable on various goods imported into Uruguay, as follows:—

Designation of Articles.	Rates of Duty now leviable.
Prussian blue, common, for washing	Pes. Cts. Kilog. (gross wt.) 0'01
Soap, common	" " 0'08
Candles of stearin, including case	" " 0'16

CANADA.

Customs Decision.

The *Canada Gazette* for the 6th July last contains the following Order of the Governor-General of Canada in Council:—

Whereas a difference of opinion has arisen as to the Customs duty payable under the tariff on ferro-manganese, ferro-silicon, spiegel, steel bloom ends, and cross ends of steel rails when not for the manufacture of steel—

His Excellency, under the authority conferred upon him by section 5 of the Customs Amendment Act (51 Viet. c. 14.), and by and with the advice of the Queen's Privy Council for Canada, is pleased to direct that such articles when imported for other purposes than for the manufacture of steel shall be rated for duty under item 41 of Act 50 & 51 Viet. c. 39, at the rate of 4 dols. per ton, and that the Order in Council of 4th June 1889 be cancelled.

CAPE OF GOOD HOPE.

Tariff of Rebate Rates.

The Cape of Good Hope *Government Gazette* for the 25th June says that, under section 5 of the Customs Union Tariff Act of 1889, his Excellency the Officer Administering the Government of the Cape has directed it to be notified that from and after the 1st July 1889, rebate to the extent shown in the following tables was to be granted in respect to such articles as are specified, whenever any such articles are removed overland to British Bechnanaland and the South African Republic:—

Articles.		Rebate to be granted.	Duty less Rebate to be paid.
Candles.....	Lb.	£ s. d. 0 0 1½	£ s. d. 0 0 1
Copper in sheets		12 % <i>ad val.</i>	Nil.
Dynamite.....	Lb.	0 0 2	0 0 1
Guns of all description		12 % <i>ad val.</i>	Nil.
India-rubber (unmanufactured)		"	"
Oils of all descriptions, other than chemical, essential, and perfumed	Imp. gall.	0 0 6	0 0 6
Do. chemical, essential, and perfumed		10 % <i>ad val.</i>	5 % <i>ad val.</i>
Ores and minerals, crude		12 % <i>ad val.</i>	Nil.
Rosin		5 % <i>ad val.</i>	5 % <i>ad val.</i>
Soap, common	100 lb.	0 3 5	0 0 9
Soda, caustic		5 % <i>ad val.</i>	5 % <i>ad val.</i>
Tallow	100 lb.	0 2 7½	0 1 6½
Turmeric	"	1 4 3½	0 0 8½
Turpentine	Gall.	0 0 10½	0 0 1½
Varnish	"	0 0 6	0 0 6
Vinegar.....	"	0 0 5½	0 0 0½

REPORT FOR THE YEAR 1888 ON THE TRADE OF FRANKFORT-ON-MAIN.

(*Diplomatic and Consular Reports*, 1889, No. 573.)

The report of the Frankfort Chamber of Commerce for the year 1888 contains the following remarks with reference to Great Britain:—

"The commercial relations between Great Britain and Germany have maintained last year the same steady and even course which trade generally pursues if not disturbed by tariff difficulties or other obstacles thrown in its way.

"Exports and imports have risen; we rejoice at this improvement of British trade, and do not complain of our position. The deficiency in the export of our productions in iron of every description, quoted specially as a proof of our failing capacity to compete, gives us no uneasiness whatever, the more so as our works are in full activity for the much more remunerative home market.

"Our statistics show no material decrease in exports to the United Kingdom, the deficiency in one article being counterbalanced by the increase in another.

"Sugar shows a falling off of 1,200,000 double cwt. as against 1887. Export of wine in bottles has decreased, whilst in casks it has increased.

"Our imports from the United Kingdom have increased in bleaching powder, the manufacture of which has diminished in Germany in consequence of the introduction of the Solvay process.

"The following articles likewise showed an increase, viz., bone-black, saltpetre, pig iron, iron ores (reaching us from England by way of transit only), machines, coal, bitumen, and linseed oil in casks."

"SUMMARY OF VALUES" OF IMPORTS AND EXPORTS FOR THREE YEARS.

	IMPORTS.		
	1886.	1887.	1888.
Drugs unenumerated	£ 104,410	£ 101,846	£ 111,471

In brandy matters were quite exceptional in the first half of the year owing to the fact that it being a period of transition the excise officers were without instructions, and the distillers and dealers did not yet understand the workings of the new law. Goods on which the new duty was paid could hardly be sold, whilst others were kept in store awaiting the new arrangements. Matters improved only with the increased facilities for permits, and the introduction of special licenses enabling the working of material on which duty was unpaid. From this period dates also a more active sale in raw materials. From this same period dates also the scheme of forming a spirit syndicate, which prospect, however, proved a failure; as also another, conceived by the Frankfort dealers, to establish a spirit factory independent of the northern establishments. In the liquor trade the high tariff caused quite a stagnation, the sales were trifling, and a profit was out of the question; there was a tendency to bring inferior brands into the market.

The total import and export of spirits was as follows:—

	Meter-cwts.
In 1888 imported.....	21,654
1887 ".....	28,609
1888 exported	11,100
1887 ".....	8,252

EXTRACTS FROM BRITISH AND FOREIGN CONSULAR REPORTS.

PHOSPHATE MINES AT REDONDA.

(*American Consular Reports, Feb. 1889, p. 206.*)

The island of Redonda, where the phosphate mines in question are found, is situated about 25 miles south-west of Antigua in latitude 26° 6' and longitude 61° 35', and is under the jurisdiction of the British Government. It is estimated to be 1 mile in length, $\frac{1}{2}$ of a mile in width, and 1,000 ft. in height. Its shores are rock-bound and the only landing place is on the south-west side, near the foot of a ravine in a cliff which is nearly 1,000 ft. high in the highest part. The mines are situated on both the north and south ends of the island.

Phosphate of alumina was discovered at Redonda about 1865, and a license to mine the phosphate for 21 years at the rate of 20*l.* per annum was obtained. About 10,000 tons were mined, but the speculation proved a ruinous one, and in December 1882 the license was surrendered. A new one was granted to the Redonda Phosphate Company in January 1883 for 21 years, on condition that a royalty of 6*d.* a ton be paid on all phosphates exported and not less than 100*l.* be paid for each half year. The shipments of phosphate by the present company began in the latter part of 1885, and have amounted in all to about 21,000 tons, valued at 24,544*l.* f. o. b. Of this quantity 4,850 tons have been shipped to the United States and were invoiced at the rate of about 24*s.* a ton; the remainder was shipped to the United Kingdom. There were 2,000 tons of the rock ready for export in December 1888.

The mining is confined to the surface and the good rock is found in veins. The drilling is done entirely by hand drills with the aid of "rack-a-rock." Some of the rock contains 35 per cent. of phosphoric acid, and that sold is guaranteed to contain not less than 30 per cent. It contains

a large proportion of iron. The supply is stated by experts to be inexhaustible.—C. G. C.

OPPORTUNITIES FOR TRADE IN MALTA.

(*American Consular Reports, April 1889, p. 583.*)

The American Consul at Malta points out that some of our manufacturers are losing grip of the trade of Malta and other of our colonies owing to the fact that they make articles more for sale than for use, and he emphasises the fact that integrity in manufacturing is as essential to success as honesty in dealing. He recommends the sending of commercial travellers carrying nothing for sale, only samples, who should take a room and invite dealers to come and inspect. These travellers should be of good address and speak the language of the country. Soliciting trade by circulars was throwing money away. Patent medicines are already widely sold, but the trade could be increased. Petroleum stoves ought to be sold in greater numbers—they are just the thing to use in hot weather. The writing paper there is poor stuff, all sent from England—of the well-known colonial grade—that is cheap and nasty. There are 19 newspapers published in the island.—C. G. C.

CHINA.

Increase of Opium Culture.

The British Consul at New Chang, in Northern China, reports that the importation of Indian opium into his district is falling off to such an extent that another year or two might see it out of the market altogether, were it not that a few well-to-do natives, mostly southerners, will always be found who prefer to give a higher price for their old favourite. The cultivation of the native poppy is making enormous strides, and the great danger of famine which the

authorities have to face in any exceptional year will be largely increased, owing to so much of the land being devoted to the poppy instead of to food staples. Some idea of the local consumption of opium may be arrived at from the following figures, which are obtained from reliable Chinese sources. There are in the port of Yingtzü alone some 2,000 opium shops. An average sale of opium in a day is 5 oz. This gives 2,244 piculs a year for the public opium shops alone. To this must be added what is smoked in private houses, which is estimated at about 1,500 piculs, and this, it must be remembered, is for Yingtzü only, and those few villages round about which are most easily supplied from here. Twenty years ago 2,685 piculs of Indian drug were imported to supply not Yingtzü, but almost the whole of Manchuria, east of the district supplied through Tientsin, for, though it is true that the native opium was started as long as 21 years ago, it was only on a very small scale, and it found very little favour until quite of late years. The population has increased very rapidly, but not in the same proportion as the native opium, and the conclusion is inevitable that opium smoking has increased enormously.

Chinese and Indian Teas.

One of the great advantages which Chinese teas are said to possess over those of India is their greater wholesomeness. On this subject the British Consul at Hankow, in his last report, gives a table of analyses of the two kinds of tea made by Professor Dittmar, F.R.S., from which it appears that the quantity of tannin in Indian tea is 9.68 per cent. and in Chinese 6.01. After 20 minutes' infusion of 100 grains of each there is present in the respective liquors 2.96 grains theine and 6.53 grains tannin in the Indian and 3.37 grains theine and 3.86 grains tannin in the Chinese tea. "The teas in question," concludes Mr. Allen, "were both high-class teas, and the analyses given above certainly tend to show that there is an excess of tannin, with all its astringent and deleterious qualities, in the Indian tea."

TRIPOLI.

Drugs and Perfumery.

Drugs and perfumes are by far the most important articles of import into Bengazi, a port on the coast of Tripoli which carries on its principal foreign traffic *via* Malta. Last year 7,500 cwt. of these articles, valued at 37,500*l.*, were imported into Bengazi, against only 720 cwt., worth 3,600*l.*, the year before. Of oil and soap the imports were worth 10,650*l.*, against 10,400*l.*, the year before. The harvest last year appears to have been very good, and, as the Consul says, an abundant harvest means large purchases of drugs, perfumes, and certain luxuries. A Manchester firm has recently started a branch agency at Bengazi.

TURKEY IN EUROPE.

Gum Tragacanth.

Constantinople was formerly the great market for gum tragacanth, but it is now shipped extensively from Bagdad, Beyrout, and Mersine, to which ports the entire produce of Syria and Arabia is at present despatched. In 1887 the business done in this gum presented no noticeable feature, but in 1888 there was a brisk demand for the best qualities from London, and a consequent increase in the supplies, though not in prices. The exports were, in 1887—88, 1,200 cases, and in 1888—89, 2,000 cases.

Opium at Constantinople.

The exports of opium from Constantinople for the years named respectively were as mentioned below, the cases containing 155 lb. each:—

Year.	Arrivals.	Exports.
	Cases.	Cases.
1886—87	768	906
1887—88	2,790	2,243

Consignments of this article to America have considerably increased during the past year.

VICTORIA.

Trade in the Colony.

Among the exports of Victoria-made articles from the colony of Victoria during the quinquennium 1883—87 are named:—

	1883.	1884.	1885.	1886.	1887.
	£	£	£	£	£
Drugs and chemicals...	15,400	12,398	17,144	13,164	10,647
Soap	12,709	15,559	18,189	13,354	10,482
Oilman's stores	13,133	15,421	14,400	11,898	13,622

In 1887, according to value, over two-fifths of the Victorian imports were from, and nearly half the exports were to, the United Kingdom. About 38 per cent. of the former, and 40 per cent. of the latter, were conveyed between Victoria and the neighbouring colonies, chiefly New South Wales. In regard to foreign countries, the imports therefrom amounted to 12½ per cent. of the total imports, and the exports thereto to over 7 per cent. of the total exports.

The imports of foreign goods into the colony show considerable fluctuations, as will be seen from the following quinquennial table:—

Imports.	1877.	1882.	1887.
	£	£	£
Drugs and chemicals..... Value	54,191	84,365	92,155
Opium	79,149	77,089	37,280
Paints and colours.....	60,486	79,636	71,436
Tea	599,725	745,226	694,898
Oils	241,001	183,558	198,074

The import duties received in 1886 and 1887 amounted to nearly 12 per cent. of the total value of imports. Some idea of the extension of Victorian commerce may be formed from the circumstance that, although the population of the colony increased by less than 60 per cent. during the twenty years ended with 1887, the tonnage of vessels entered and cleared in the last as compared with the first year of that period increased nearly threefold. The number of miles of railway open in the colony on June 30, 1887, was 1,880, consisting of 1,643½ miles of single and 236½ miles of double line.

THE CHINA TRADE AT LIMOGES.

(United States Consular Reports, 1889, 386—389.)

Further improvement took place in this trade in 1888. The following table shows the number of furnaces fired during each year from 1882 to 1888:—

Year.	Coal.	Wood.
1882	2,590	507
1883	2,230	544
1884	1,805	448
1885	1,560	335
1886	1,528	323
1887	1,621	324
1888	1,705	339

The increase in manufacture is due to a better attention to the requirements of modern business, a withdrawal from competition in certain lines, and special devotion to those branches of manufacture which could be worked with the best advantage. As a result the trade consists of dinner and

tea ware, higher grade, ornamental, and decorated work, such as vases, plaques, bisque figures, &c. Machinery has largely supplanted hand labour, with the result that the waste unbaked broken ware is all reground and used, and the broken china is used as an ingredient in the enamel. Machine moulding is also an advantage. A great gain has been made also by an improvement in the construction of Minturn's reverse flame furnace. Instead of the flames from the lower chamber passing up into the upper one through the centre, they are made to enter the latter through apertures in its floor, thus adapting the same principle to heat both. There are as many apertures—generally about 10—as there are fire-boxes, and the second chamber is thus heated evenly. By this improvement 25 per cent. of fuel is saved, and 30 per cent. in the breakage and quality of the china. The furnaces now are one-fourth larger than formerly, consequently the 2,044 furnaces fired last year really correspond to 2,555 of the 1882 type. There has been a rise in the value of the decorated ware from 300 francs per cask to 500 francs. The amount of china decorated in the locality last year was valued at over 11 million francs, and that together with the white manufactured at Limoges at about 18 million francs. The price of labour varies very little, but there has been a decrease of 10 per cent. in 10 years. There are no strikes, as both the manufacturer and the workman has his own syndicate, and all disputes are settled by a joint committee. The price of English coal has advanced $5\frac{1}{2}$ francs per ton, but all other materials remain the same as last year. Trade prospects are good, heavy orders from the United States being reported.—A. W.

MANUFACTURE OF ZINC IN BELGIUM.

(United States Consular Reports, 1889, 441—447.)

The eleven works of the various Belgian companies are all in full work. In 1882 the output of each company was as follows:—

	Tons.
Vieille Montagne.....	35,940
Austro-Belge.....	8,009
De Laminne.....	6,255
G. Dumont and Bros.....	5,500
Nouvelle Montagne.....	5,480
Bleyberg.....	4,647
Ougrée.....	4,144
Prayon.....	1,500
Total.....	71,565

This total represents about one-third of the whole production of Europe. In 1887 the Vieille Montagne Company alone produced over 60,000 tons, and the other companies have also increased their out-turn. All the works receive part of their supplies of ore from abroad, first from Spain, and later from Sardinia, Greece, Algeria, Sweden, France, Germany, and England.

Belgium manufactures, yearly, about 40,000 tons of rolled sheet-zinc, and the Valentine Coeq. works of the Vieille Montagne Company produces annually 3,000 tons of zinc white. The production of zinc exceeding the demand, a syndicate was formed last year by the members of the Franco-Belgian group for the limitation of zinc production, when the amounts agreed upon were as follows:—

	Agreed Maximum Production in Tons.
Vieille Montagne.....	52,532
Company Royal Asturienne.....	15,574
Society Austro-Belge.....	9,270
Mr. L. De Laminne.....	6,697
Company Escambrera Bleyberg..	5,579
Nouvelle Montagne.....	5,168
Eschger, Ghesquire and Co.....	4,030
Society Metallurgique de Prayon.	3,965
	102,755

—A. W.

MISCELLANEOUS TRADE NOTICES.

NEW REGULATIONS CONCERNING EXPORT OF MEDICINAL TINCTURES.

The following letter has been received in reply to one from the Chairman of the Chemical Trade Section of the London Chamber of Commerce:—

"Inland Revenue, Somerset House,

"Sir,

"1st August 1889.

"I AM directed by the Board of Inland Revenue to acknowledge the receipt of your letter of the 26th ultimo, and to acquaint you in reply that further amendments to the regulations as to the exporting of medicinal tinctures will be introduced, so that in future the name of the person for whom the tinctures are bottled, or some distinguishing mark without the name, will be allowed to be placed on the outside of the case instead of the maker's name, on condition that the licensed maker, after filling in the form 114—4, will write after the particulars of notice the full name and address of the person for whom the tincture is bottled and in whose name it is to be exported, or specify instead the distinguishing mark which the exporter intends to use.

"General instructions on the subject will be issued to the Board's officers without delay.

"I am, Sir,

"Your obedient servant,

"ROBERT MICKS,

"Secretary."

THE SALT DEPOSITS OF IRELAND.

(See this Journal, 1887, p. 688.)

The new salt mine at Carrickfergus has been sold to Charles Tennant and Co. (Limited), chemical manufacturers, Glasgow, who have commenced boring operations.—*Chemist and Druggist*.

BARYTES IN IRELAND.

A barytes mine has been discovered at the foot of Mount Gabriel, on the Rosbrin estate, co. Cork. Samples of the mineral have been sent to England, and have been considered excellent.—*Ibid*.

PREPARATION OF CHINA GRASS.

(Journ. Soc. Arts, Nos. 1888 and 1890.)

In a late number of the "Kew Gardens Bulletin of Miscellaneous Information," is a report on the series of trials of methods for preparing China grass, undertaken by the French Government, which was drawn up by Mr. D. Morris, Assistant Director of Kew Gardens, who attended the trials on behalf of the India Office. The general conclusions drawn after a tolerably exhaustive inquiry and report are of considerable interest, and they may be stated as follows:—

There is no doubt that China grass is exciting great interest in many parts of the world, and many people are experimenting with various processes for extracting the fibre cheaply and quickly. Up to the present no results are quite satisfactory. The fibre is either imperfectly freed from gummy matter, or the process breaks down in the matter of cost, or owing to the local conditions under which it must be carried on. No system of preparation which cannot produce the clean, unbleached fibre under 30l. per ton, is likely to succeed in establishing this article firmly in the estimation of English textile manufacturers. It is quite possible that some machine or process will eventually solve the problem, but the exploitation of China grass, in spite of years of labour, and the expenditure of large sums of money upon it, cannot be said to have yet emerged from the experimental stage.—*Ibid*.

MINERAL INDIA-RUBBER.

An article formerly considered worthless has been added to the useful products, and is known as mineral india-rubber asphalt. It is produced during the progress of refining tar by sulphuric acid, and forms a black material

very much like ordinary asphalt, and elastic like india-rubber. When heated so that the stony matter is reduced to about 60 per cent. of its former size, a substance is produced hard like ebony. It can be dissolved in naphtha, and is an excellent non-conductor of electricity, and therefore valuable for covering telegraph wires and other purposes where a non-conducting substance is needed. Dissolved, the mineral india-rubber produces a waterproof varnish. The manufacture of the material is said by an exchange to be profitable.—*Engineering and Mining Journal*.

THE REPORT OF THE BERLIN CHAMBER OF COMMERCE.

The report of the Berlin Chamber of Commerce on the condition of the drug and chemical branches in that city during the year 1888 asserts that so far the only result of the incorporation of Hamburg into the German Customs Union has been a considerable increase in the Hamburg charges on the handling of merchandise, a perceptible decrease in the promptness with which goods are transhipped in that port, and the creation of competition of the Hamburg traders in the interior of Germany. The exceptionally low value of the Russian exchanges, the severe winter and consequent delay in the opening of river and sea communication, and the uncertainty of the political situation, were the reasons that business during the first half of the year remained very unsatisfactory. Later on a remarkable increase in the export trade of drugs and chemicals became perceptible. On the whole the industrial combinations and conventions, the number of which is constantly growing, have not operated to the disadvantage of the industry. A striking feature in the drug trade is the growing popularity of certain American drugs, especially *casearia sagrada*, *hydrastis canadensis*, and *senega*. The trade in German vegetable drugs, on the other hand, especially for export, is falling off seriously, and even prices at which the planters cease to have any profit fail to rehabilitate this branch of trade. The manufacture of chemical and pharmaceutical preparations has been very brisk, and is still rapidly growing.—*Chemist and Druggist*.

THE TRADE IN MASTIC.

The price of mastic, in common with that of so many other products, has been at a very low ebb of late, so low in fact that the Administrative Council of the island of Chio, in the Greek Archipelago, where the mastic is obtained, and where its collection forms an important branch of industry, have recently made a study of the best means of raising the price of the article. Among other measures it was decided to prohibit: (1.) The repeated incisions in the trees. (2.) The offering for sale of impure, yellow, or black mastic. (3.) The mixing of the native product with dust or with residues of the tree bark, more or less impregnated with mastic. Since these measures have been adopted and carried out, the price of the mastic is said to have advanced locally to an appreciable extent, and the Government of the island now inform the commercial world that, for the future, the bark of the mastic resinous trees must not be tapped more than twice a year, and that at fixed and determined periods. The only kind of mastic which is allowed to be gathered is the white mastic, free from powder or from any other foreign substance.—*Ibid*.

SCHNEIDER AND CO.'S PATENT COPPER CASTINGS.

Schneider and Co., Creusot, France, have patented a process, which consists in making, in a blast furnace, a cupola or a reverberatory furnace, castings having a variable proportion of copper with a proportion, likewise variable, of the ordinary constituents of cast iron. These copper castings are used for the manufacture of the copper steels which serve for the preparation of articles such as sheathing and armour for vessels, cannon, projectiles, bed-plates, steam cylinders, rolls, &c., the articles, when desired, being case-hardened or hardened in oil. Copper ore is mixed with the charge in the blast furnace, or copper alloys with the charge in the cupola. Also copper filings can be mixed with coal to form a copper coke, which is used for heating the blast furnace or cupola; or copper compounds can be

melted in a reverberatory furnace, with a mixture of steel or iron under a layer of anthracite to prevent oxidation.—*Ironmonger*.

INTERNATIONAL CONGRESS OF CHEMISTRY.

The International Congress of Chemistry was opened on Tuesday, July 30, at precisely 8.30 p.m., by M. Berthelot, in the grand amphitheatre of the Arts-et-Métiers Conservatory. The attendance was large, and included a number of foreigners. M. Berthelot briefly exposed the objects of the Congress. "Theories are not to be considered," he said, "but only practical questions, such as relate to analytical methods and nomenclature. The last urgently needs revision and improvement. The system hitherto followed has become insufficient. So many new compounds have been discovered that they are bursting through the frames formerly intended and thought wide enough to contain them. This is especially true of the hydrocarbons and the numberless substituted azo-compounds derived from coal distillation, and used in pharmacy and the arts. We cannot keep on adding syllables and forming endless names for new combinations. A new and clearer system is absolutely necessary, with lines broad enough to last for some time at least." After expressing his wishes and hopes for successful results, the chairman, on behalf of the organising committee, proposed for the various sections of the Congress the names of presidents and secretaries, which were unanimously confirmed. They were as follows:—Section I. Unification of the Nomenclature in Organic Chemistry: president, M. Riche; secretary, M. Bischof. Section II. Chemical Analysis of Organic Bodies: president, M. Joulie; secretary, DeMoussy. Section III. Analysis of Alimentary Substances: president, M. Friedel; secretary, M. Bouvean. Section IV. Analysis of Pharmaceutical Products: president, M. Petit; secretary, M. Boequeron. Wednesday and Thursday, at 3 p.m., were set apart for considering the questions of cinchona, opium, quinine, chloroform, phenol, pepsin, salicylic acid, and analgesin analysis and testing. On Wednesday afternoon, at the hour appointed, the meeting was resumed, with M. Petit in the chair, assisted by Secretary Boequeron and MM. Marty, Konya, of Roumania, and Rio de la Loza, of Mexico. The testing and assaying of quinine, cinchona bark, and morphine were the subjects of an earnest exchange of views between Professors Marty and Jaogleich and MM. Petit, Boequeron, Taillandier, Tanret, Léger, and others. In respect to quinine and cinchona assay, the conclusions arrived at were that the Codex tests, as modified by the Paris Society of Pharmacy, and supplemented by polarimetric tests, are necessary, but sufficient for a pharmaceutical estimation. As regards morphine, after a long discussion a committee was appointed, composed of MM. Yvon, Tanret, Boequeron, and Petit, to embody the views expressed, and present them to the general meeting.—*Ibid*.

RAILWAY RATES.

A very large meeting was held at the Mansion House on Friday, July 26, under the presidency of the Lord Mayor, "for the purpose of considering what further steps should be taken to prevail upon the railway companies to agree to terms more equitable to traders, and also to establish a central organisation for concerted common action among the mercantile representatives." The meeting gave evidence of the unanimity of the trading classes of the country in condemnation of the unfair classification of goods which has been proposed by the railway companies. It was resolved, on the motion of Mr. Howard, that in view of the serious objection taken to the classifications submitted by the railway companies, the Board of Trade should invite the aid of a commission of experts with the object of assisting the department to frame a classification upon a fairer basis than that presented. After 40 years' experience in railway work, the mover said, it could not be impossible to make a proper classification. Other countries had done this, and what was possible with others should be possible to Great Britain. It was also resolved to form an association to concert common action and to be representative of agriculture, commerce, and of the various other interests affected.—*Chemist and Druggist*.

DEODORISING OPERATIONS.

At the weekly meeting of the London County Council, held at the offices, Spring Gardens, S.W., on July 30th, Lord Rosebery presiding, the Main Drainage Committee reported that they had received from the chemist a further report on the condition of the River Thames, and on the deodorising operations. The report was to the effect that the river was now in a much more satisfactory condition, the change in the weather having effected a material improvement. With regard to the deodorising operations, the chemist stated that, from July 11 to 20, 128 tons of manganate and 47 tons of sulphuric acid had been used at the outfalls, and 9 tons of manganate and 2 cwt. of sulphuric acid at the various storm overflows. The quantity in stock on the last-named date was:—At the outfalls: manganate, 16 tons; sulphuric acid, 31 tons. At the storm overflows: manganate, 37 tons; sulphuric acid, 15 tons. The committee recommend that the seal of the council be affixed to the following documents:—(Contracts with Messrs. C. Tennant, Sons, & Co., the Widnes Alkali Company (Limited), and Middleton, Kirkpatrick, and Barr, for the supply of manganate of soda; and with Sadler & Co. (Limited), for the supply of sulphuric acid. The recommendations were approved without discussion.—*Ibid.*

The Basic Bessemer Process in the United States.
W. B. Phillips. Eng. and Min. Jour. 1889, 2, 30.

THE following tabulated figures showing the world production, in tons, for the past eight years, of both acid and basic Bessemer iron, have been collected from various sources and are approximately accurate:—

—	Basic.	Acid.	Per Cent. of Ratio.
1881	260,000	4,333,470	4.44
1882	572,604	4,687,143	10.83
1883	634,373	4,482,719	12.39
1884	864,000	3,338,145	18.00
1885	945,317	4,090,831	18.80
1886	1,313,631	4,814,361	21.50
1887	1,702,252	5,647,741	23.15
1888	1,984,184	4,912,171	29.10

The production of basic slag in 1888 was 600,000 tons.

The Causes of the Principal Defects of Wrought Iron.
A. D. Elbers. Eng. and Min. Jour. 1889, 2, 31.

THE author, after quoting from Karmarsch (edition of 1866, Hanover), gives his own views in explanation of the properties of cold, blue and red-shortness of different kinds of iron, and endeavours to connect the effects of impurities at various temperatures with the properties of those impurities themselves under similar conditions, but admits that his remarks are not intended to appear authoritative. An impurity with less tenacity than iron tends to render the latter cold short, and, if the dissimilarity increases on heating, also blue and red short. If the impurity melts below a red heat the injurious effect is still greater as the temperature increases, until the iron commences to lose its own rigidity, when it decreases,

CALIFORNIA BORAX.

New borax works have recently been started in Saline valley, Inyo county. They have 18 crystallising tanks, each of a capacity of 1,000 gallons. Three of these tanks are emptied daily, yielding about two tons of borax. The crude material from the borax marsh is first boiled in a boiler of 3,000 gallons capacity, and the solution is then run off into the tanks, where it is allowed to cool off and crystallise for about six days. The borax accumulates on the zinc sides of the tanks, and on plates of that metal hung in them, seven being used to each tank. The works are about 55 miles from Alvord station, and are close to the great Inyo mountains, which rise like a wall to a height of 11,000 feet above the sea level.—*Scientific American.*

Quicksilver in Russia. W. A. Abegg. Eng. and Min. Jour. 1889, 2, 26.

THIS is a description of the recent working of a new cinnabar mine in the Baku mouth district of Russia.

The lode is estimated to contain 194,000 tons of ore, containing nearly 1 per cent. of mercury.

The ore is blasted with dynamite (90½ lb. of dynamite for about 18 tons of ore), and, after crushing, is divided into four classes according to size, the finest being the richest.

The output of ore for the first year of working, 1887, was 11,527 tons of 2,000 lb. separated into the following proportions:—

About 2.5 per cent. of No. 1 ore, containing 4.85 per cent. of mercury.

About 10.0 per cent. of No. 2 ore, containing 2.20 per cent. of mercury.

About 15.0 per cent. of No. 3 ore, containing 1.23 per cent. of mercury.

About 72.5 per cent. of No. 4 ore, containing 0.65 per cent. of mercury.

The works delivered, in 1887, 141,009 lb. of quicksilver, and in 1888, 362,366 lb., but furnaces have been put down capable of producing over 800,000 lb. per annum. The following table shows the particulars of production by the various systems used:—

whereas an impurity which is then more rigid than iron tends to lessen its plasticity. This is said to explain apparent inconsistencies, such as copper rendering iron red and weld short, and sulphur only cold short.

Explanations are also given of the causes of iron losing its tenacity by repeated heatings, by which it is demonstrated that iron with small quantities of impurities is apt to be affected more quickly in this respect than iron containing a larger quantity of them. Finally the causes of the appearance of different fractures are discussed.—A. W.

JAPAN AS A COAL PRODUCER.

(Eng. and Min. Jour. 1889, 2, 32.)

VAST coal fields have recently been discovered in the islands of Kinsin and Yesso. Karatin coal beds exist five feet in

thickness and extend over an area of 120 square miles. Collieries exist near Tokio, anthracite has been found in the island of Amakusa, and lignite can be obtained in all the Japanese provinces. The total output in 1881 amounted to about 700,000 tons, and has since been steadily on the increase. The machinery employed is chiefly German.

—A. W.

VICTORIAN DRUG DUTIES.

It has been proposed in the Victorian Legislature to admit duty free the following drugs now dutiable:—Carbolic, oxalic, and picric acids, aloes, cannabis indica, faba amara, grains of paradise, potassium (bromide), potassium (iodide), and quassia. Perfumery to be increased from 10 per cent. to 20 per cent.—*Chemist and Druggist*.

CONSUMPTION OF QUININE IN THE UNITED STATES.

The imports of foreign-made quinine into the United States between January 1 and August 3 have been 1,877,614 oz. against 997,200 oz. during the corresponding period of 1888. In St. Louis and other districts liable to malarial fever quinine is said to be in better demand this year than in any previous season.—*Ibid*.

THE TRADE IN KOLA NUTS.

The trade in kola nuts in the British settlements of Gambia (West Coast of Africa) is increasing. The imports during the year 1887 were 356,579 lb., and in 1888 409,735 lb. The import duty of 1d. per lb. on the nuts has recently been reduced to $\frac{3}{4}$ d. per lb.—*Ibid*.

THE GERMAN CUSTOMS DUTIES.

The German Customs duties yielded 290,160,365 m. in 1888, against 270,446,981 m. in 1887. Drugs, chemicals, and dyestuffs together brought in 1,022,798 m., and 1,000,074 m. respectively. The most remunerative articles of this class are dyewood extracts, from which was collected last year 181,845 m.; bleaching powder, 175,233 m.; lacquers and varnishes, 117,220 m.; glue, 67,299 m.; caustic soda, 66,948 m., and oil varnishes, 63,240 m.—*Ibid*.

INSECT FLOWER GROWING IN CALIFORNIA.

It appears that insect flowers (*Pyrethrum cinerariaefolium*) are now being grown on a large scale in California, and that the powdered flowers are sold in that State under the name of buhach. The plant was first introduced into California about 12 years ago by a Mr. Mileo, a native of Dalmatia, who succeeded, after some trouble, in growing the plant on an extensive scale, and in 1880, associating himself with other capitalists, established the Buhach Producing and Manufacturing Company. At the present time the company have about 300 acres of this plant under cultivation at their farm near Atwater, Merced county, California, and own mills for grinding the dried flowers to powder at Stockton, near San Francisco. The cultivation of the *Pyrethrum* requires careful and intelligent supervision, and it cannot be grown successfully without irrigation. It requires three years from the time of sowing to grow plants capable of producing a paying crop of flowers, and then they will bear from four to five years longer. It is at its prime, however, in its fourth or fifth year. The plant grows about 30 inches high, and is set out in rows 4 feet apart, and from 15 to 24 inches apart in the rows. The flowers are harvested towards the latter part of May. The stalks are cut just above the roots, and the flowers stripped from them by passing the plants through a kind of comb. The detached flowers fall into a box below, and are carried to the drying-ground, where they are spread on sheets and exposed to the rays of the sun during the day, being repeatedly turned over in the meanwhile. They are covered during the night to prevent their absorbing moisture, as the perfect drying of the flowers is most important in order to retain the volatile oil which gives the powders its insecticide properties. It is also very necessary that this operation should be done quickly, and that the flowers during the drying process should be protected from moisture. A slight dew falling upon the flowers at this time will injure their colour, and reduce their strength

as an insect destroyer. In this respect the Californian-grown flowers are said to be better cured, and consequently more valuable, than those produced in Dalmatia, the particular conditions of soil and climate in California being extremely favourable to the growth and curing of plants rich in the essential oil which renders them so destructive to insect life.—*Ibid*.

RUBIDIUM.

Professor Laufenauer publishes in the "Therap. Monatsch.," a preliminary note on rubidium-ammonium-bromide. The double bromide was used as being cheaper than the rubidium bromide. It consists of $\text{RbBr}_3(\text{NH}_4\text{Br})$, representing in 100 parts 36 parts RbBr and 64 NH_4Br . The author has studied its epileptic action in 17 cases, the doses given varying from 1 drachm to 2 drachms; the effect was similar to that produced by potassium bromide, but more intense. The hypnotic action was very satisfactory. On the whole it acts very like the other alkaline bromides, but more decidedly. The author reserves to himself the priority of using similar compounds of cesium.—*Ibid*.

DISCOVERY OF MINES IN SWEDEN.

A company which was formed this year for the purpose of prospecting the district of Gellivara, in Sweden, has discovered extensive mines of argentiferous lead, copper, manganese, graphite, and iron to the north of Gellivara, and at no great distance from the railway. The lead ore, which exists in great abundance, is said to contain more silver than that found in the celebrated Sala mines, and is pronounced by experts to be the richest ore of the kind hitherto found in silver. Gold sand has also been met with in some of the mountain streams. About 30 years ago some Russian geologists obtained 5 lb. of gold and some platinum in the same neighbourhood after working for a few weeks, but the washings were abandoned, owing to the Government insisting that the Russians should become Swedish citizens. The copper mines at Skrikerum, which had not been worked since 1832, have recently been reopened under the management of Professor Blomstrand, Luna, and Dr. Rudelins. It was in these mines that selenium was first discovered by Berzelius in 1817.—*Ironmonger*.

IMPORTANT DISCOVERY OF URANIUM IN CORNWALL.

A few weeks ago the Devon and Cornish papers reported a very rich find of the rare and precious metal known as "uranium." It now transpires that the discovery is of even greater importance than was at first thought. A continuous lode of this mineral has been opened, a thing perfectly unique in its history since the mineral was first discovered by Klaproth, a German chemist, exactly 100 years ago. Klaproth isolated from a dark-coloured material known as pitch-blende a yellow oxide which he, after testing, declared to be the oxide of a new metal, to which he gave the name of uranium in honour of the planet Uranus, which Herschell had then recently discovered. Different varieties of uranium were shortly afterwards found in districts of Bohemia and Saxony, and after the lapse of several years traces of the precious ore were found in Cornwall. Curiously enough, the enormous find of uranium at Grampound Road, in Cornwall, has taken place in the centenary year of the original discovery. Hitherto this mineral has only been found in pockets and patches. The discovery at Grampound Road is what is known as a true fissure vein, and the ore contains an average of 12 per cent. of the pure metal, going up as high in many places as 30 per cent. The importance of the discovery will be understood when it is stated that the market price of the pure metal is 2,400l. per ton.—*Ibid*.

THE ADULTERATION OF LARD IN THE UNITED STATES.

The following information respecting the adulteration of lard in the United States is extracted from a memorandum recently issued from the Agricultural Department of the Privy Council Office:—

It appears from a report just published by the United States Department of Agriculture, and prepared under the

direction of the chemist at the head of the division of chemistry, that lard is very largely adulterated with cotton-seed oil and fat from animals other than pigs.

Lard is technically the fat of certain parts of the pig. This is the British idea of lard, but according to the chemist of the United States Department of Agriculture, lard is a term applied to the fat of the slaughtered hog, separated from the other tissues by the aid of heat; but he admits that the heads and much of the viscera and other parts of the animal are put into the "rendering tanks," and, indeed, by the definitions of the Chicago Board of Trade, any part of the hog containing fat can be legally used for the manufacture of lard.

With respect to the fat of other animals than pigs, it is stated that oleo-stearin, made chiefly from the caul fat of cattle, is employed to a considerable extent to adulterate lard. This is produced in open kettles, the tallow resulting from this is placed in ears in a "granulating room," where it is allowed to remain at a temperature of from 80° to 90° F. The contents of the ears are then mixed and placed on a revolving table, where they are made into cakes. These are wrapped in strong cotton cloths and placed in a press, where a gradual pressure at 90° F., becoming very strong at the end, is applied for one or two hours. The expressed oil, known as oleo-oil, is used in the manufacture of butterine. The stearin is removed from the press as white hard cakes, and is used for adulterating lard.

It is said concerning beef fat that before the day of oleo-margarin all fat rendered from the tissues of cattle was known commercially as tallow. Since then differentiation has taken place and the term tallow is no longer sufficient to designate the several products obtained from the rendered fat of the beef. There is first "butter stock," which is rendered from the caul fat at a low temperature, and from which is manufactured by means of pressure, 1st, oleo-oil; 2nd, oleo-stearin, beef-stearin.

A fine article of mutton tallow is also sometimes used in lard, but the objection to the flavour is sufficient to limit its use to a small amount.

The term "refined lard" has long been used, says the chemist, to designate a lard composed chiefly of cotton oil and stearin. The largest manufacturers of this kind of lard have now abandoned the term, and are using the label "lard compound" instead. This, it is added, is but just to the consumers of this article, who are likely to be misled by the term "refined lard."

The natural lard in a state of fusion, the stearin from beef fat, and the refined white cotton-seed oil are measured in the proper proportions and placed in a tank at a temperature of 120° to 160° F. These various ingredients are thoroughly mixed by means of paddles worked by machinery. After it is mixed the compound lard is passed into artificial coolers, where it is chilled as soon as possible. From thence it is run off into small tin cans or large packages and prepared for market.

In external appearance and to an unskilled person it is said that adulterated lards are not appreciably different from the pure article. "An expert, however, is generally able to tell by taste, odour, touch, and grain, a mixed lard from a pure one. There is usually enough lard in the adulterated article to give it the taste and odour of a genuine one. Mixtures of fat have been made and perhaps sold as lard which contained no hog's grease whatever."

Alluding to statements that other adulterants of not so harmless a nature are used in making lard, the chemist remarks: "Among these substances dead-hog grease, or dead-hog stearin, is the one most frequently mentioned. The term dead-hog grease is used to indicate the oil or lard obtained from animals which die of disease, or are smothered in transportation, or die on the way to the slaughtering houses. The fat of animals recently dead, unless death takes place from disease, and taken before decomposition sets in, has chemically the same characteristics as that derived from animals slaughtered. If, however, the animals had been dead some time a considerable decomposition of the glycerins takes place, and the amount of free acids in the fat is thus largely increased. Such fat also shows a distinctly unpleasant odour, by which it can be readily detected from genuine lard."

Pea-nut oil and other vegetable oils are also mentioned as lard adulterants, but of these the chemist remarks: "While it may be true that many attempts have been made to use the above substances in the adulteration of lard on a small scale, it is also quite true that such attempts have never attained any importance from a commercial point of view."

CONSUMPTION OF NITRATE OF SODA IN THE UNITED STATES.

The *South American Journal*, in its issue of the 27th July, in illustration of the statement that the use of nitrate of soda is obtaining a firm footing in the United States, quotes the following statement of a leading New York firm:—

The consumption at Charleston of nitrate of soda (used chiefly in the manufacture of artificial manures) is increasing to a remarkable extent. Up to this year Charleston has never taken more than one cargo of nitrate, but in 1889 we have succeeded in placing four cargoes, and have an inquiry for another. Hitherto great difficulty has been experienced by manufacturers in getting their artificial manure sufficiently dry for the distributors when mixed with nitrate of soda. Now, however, we learn that they have entirely overcome this difficulty, and the consequence is, as we have said, that they have taken four or five times as much nitrate of soda this year as in the past, and we think there is every prospect of a still further increase in the consumption.

PRODUCTION OF COTTON-SEED OIL IN TEXAS.

The following particulars respecting the production of cotton-seed oil in Texas are extracted from a recent report by the French Vice-Consul at Galveston:—

The factories engaged in the cotton-seed oil trade in Texas produce annually 130,000 tons of oil-cake and five million gallons of oil. The latter article is forwarded to the manufacturing towns of the west and north, chiefly to Chicago, Kansas City, St. Louis, and New York. It is used as burning oil, mainly in the mines, and it is largely used for the manufacture of soaps and candles; this is the use to which it is honestly put. The unscrupulous find it most profitable in many commercial adulterations. Refined, it is sold for olive oil; mixed in certain proportions with tallow, it assumes in the market the name of fat and lard. But the great fraud was its substitution for butter. A law of the United States has put an end to this fraud by requiring the seller of oleo-margarin to declare the real nature of their product, and, for this reason, with very rare exceptions, artificial butters are no longer sold here, except as such and at prices commensurate with their composition.

It is possible that the fraud has found its way across the Atlantic and is now practised on the European side of the ocean. According to statistics published on the 7th November last, by the *New York Oil, Paint, and Drug Reporter*, it appears that from the 1st September, the date of the opening of the cotton season, to the 3rd November 1888, the Netherlands imported from the United States 229,130 gallons of cotton-seed oil. Its imports of the same product during the same period of the previous year only amounted to 3,767 gallons. On the other hand, the butter trade in the Netherlands, already very considerable, goes on increasing. This simultaneous increase in the sale of butters and in the purchases of cotton-seed oil, may be only a curious coincidence; but the case seems worthy of attention and should be noticed. The export to Germany of cotton-seed oils has also increased in a large proportion. From the 1st September to the 3rd November 1887, it was 1,849 gallons; from the 1st September to the 3rd November 1888, it reached 60,204 gallons.

SISAL HEMP TRADE AND COMMERCIAL IMPORTANCE OF YUCATAN.

In a letter to the *South American Journal* dated Merida, June 15th, a correspondent writes as follows in regard to the important progress of Yucatan:—

"To give an idea of the importance of henequen (sisal hemp), over 100,000 bales will be exported for the first six

months of this year, representing a value of over 5,000,000 dols. Last year's export reached 214,069 bales, weighing over 76,000,000 lb., and of a value of over 10,000,000 dols. gold. You can therefore easily realise how an article grown from the soil, with little or no cost attached to it, selling now at the rate of 50*l.* to 55*l.* per ton, must enrich Yucatan, which, all told, has not a population of more than 300,000 inhabitants. Yucatan, in fact, is now so prosperous that money is a drug; people do not know what to do with it, and they are willing to buy all kinds of goods, even the most costly. As I said before, here is a most favourable field for English commerce."

BENGAL OPIUM SALES.

The following is extracted from the *Calcutta Englishman* for the 22nd June last:—

It is notified that in the calendar year 1890 not more than 57,000 chests of Bengal opium will be offered for sale, and not more than 4,750 chests in each month of the year. Of the quantity to be offered for sale in each month, not more than 2,500 chests will consist of Benares, and not more than 2,250 chests of Patna opium, and no reduction will be made in this quantity without three months' previous notice.

PETROLEUM BEDS OF UPPER BURMAH.

The *Burmah Gazette* contains the following account of a survey of the petroleum beds of Upper Burmah by Dr. Fritz Noetling, of the Geological Survey:—

The oil wells of Yenangyoung, or more properly Twingoung, and Bené, have long been famous, but hitherto there has been the greatest discrepancy in the various accounts of their number and productiveness. The field at present contains 524 wells, but of these only 281 are productive; and Dr. Noetling estimates the daily yield to be at the very least 15,000 vis, or 450,000 viss a month (a viss is about a gallon), a remarkable confirmation of the estimate of Major Storer, published in 1871, which put it at 4 lakhs of vis a month. The output, however, is nothing to what it might be with proper methods and appliances. The oil-bearing strata consist of soft sandstone, which the Burman, with his primitive tools, digs through at a great expenditure of time and labour. In no case does he get lower than 310 feet, leaving nearly 100 feet of the oil-bearing stone, the richest portion of the field, wholly untouched. Under other conditions Dr. Noetling estimates that the production might be raised to 50,000 vis a day. This gives 18½ million vis a year, or about half the total importation of both Russian and American oil in 1887—88.

DISCOVERY OF COAL IN CEYLON.

The *Ceylon Observer* (overland edition) for the 10th June last announces the discovery among some samples of plumbago dug out of a Pussellawa estate, of a piece of true bituminous coal, the first, it is supposed, ever found in Ceylon.

GERMAN PETROLEUM.

Concerning the position of the German petroleum industry the following extract from the report of the Board of Directors of the United German Petroleum Works for 1888, which is just issued, gives some interesting information.

At the beginning of the year 1888 there were two borings only at Hänigsen that had been made for the purpose of obtaining raw petroleum, and during the course of the year eight more borings were undertaken.

Of these ten oil wells, six yielded petroleum, three had to be given up as useless, and one was still being experimented upon.

The output of the two older wells at Hänigsen has not appreciably diminished during the past year. At the beginning of 1888 there were twelve wells being pumped at Oelheim; of these four had to be given up, while six became more productive during the course of the year.

At the commencement of 1889 there were no less than 14 wells being pumped from.

The following figures exhibit a comparison between the outputs for the years 1887 and 1888:—

	Kilogs.
Hänigsen.....	54,342
Oelheim.....	982,003
Total (1888).....	1,036,435
Total in 1887.....	1,003,023

In the refinery at Peine raw oil was worked up as shown by the following:—

	Kilogs.
1887.....	2,323,904
1888.....	2,068,828

According to the report, negotiations are being carried on to considerably increase the refinery business in an advantageous way.

The United German Petroleum Works Company has made a net profit of 20,026 marks, which, considering the difficulties it has had to contend with, is a very fair result.—*Oil and Colourman's Journal*.

REPORTS FROM THE STATES.

Reports from the States speak of the continued decrease in the quantity of petroleum in stock. There has now been an unbroken record of decreasing stocks in each monthly statement since July 1887, and the indications warrant the expectation that stocks will continue to grow smaller, as the field developments do not show the increase in production looked for. As the season of increased consumption approaches the difference between runs and deliveries will grow larger, while the operations in the fields will be pursued under less favourable conditions. At present we are in the season of lightest demand and most favourable conditions for field work, and yet the stocks have been drawn upon to the extent of nearly half a million barrels to make up the difference between production and consumption. After the present month this gap may be expected to widen unless far better success attends new drilling ventures than has been shown during the past year and a half.—*Ibid*.

THE INDIAN TRADE IN MINERAL OILS.

The *Times of India*, with reference to the Indian trade in mineral oils, says:—

"In 1887 the imports of oil of the United States into India reached a total of 29,144,942 gallons, while last year they were only 25,040,517. The import of Russian oils, however, increased from 1,577,392 gallons in 1886—87, when the trade was inaugurated, to 5,036,055 in 1887—88, while in eight months of 1888—89 over 11,000,000 gallons were imported. Whether the progress of the trade was temporarily interrupted by higher prices or by the imposition of a duty of half an anna per gallon in January of last year is not quite clear; but there can be no doubt, as the report says, that now that the use of the oil has become so common, and its advantages, when compared with the smoky and dull light given by the vegetable oils which kerosene is superseding, are so much appreciated, it is improbable that the trade will not further advance. Petroleum in abundance has been found in Afghanistan, but its quality makes it unfit for use, except as fuel for locomotives. The petroleum of Upper Burmah is used to but a small extent for illumination, being chiefly employed for machinery. The wells of Arakan are not now worked, except in a very small way by natives, the European company formed for their working having failed. There are hopes of finding large quantities of oil in the Rawal Pindi district, where the oil is now used in a small way for making gas by the military authorities, and a concession of mining rights has recently been given on very liberal terms to an association of capitalists who propose to seek for oil in that district. But, so far, it may be said that India is entirely dependent on its imports for mineral oil for illumination. Until recently the United States have had the practical monopoly, but, as we have shown, Russian oil is now making a considerable figure in the trade."—*Ibid*.

NAPHTHA RESIDUUM AS FUEL.

Consul Michell, of St. Petersburg, writes:—Naphtha residuum is being more and more employed as fuel in Russia. All the steamers of the Caspian, and many of those plying on the Volga, have for some time past been fuelled with it. Now manufactories and railways are adopting it in the place of wood and coals. It is also being utilised for domestic purposes in stoves of special construction, ingenious specimens of which were exhibited last year at the St. Petersburg naphtha products exhibition. By the employment of this new combustible a serious saving is effected under the head of fuel. Some large manufactories in Moscow and its immediate neighbourhood employ naphtha residue in their furnaces, because, in addition to its great cheapness, it possesses the great advantage of occupying less space than wood or coals for storage. It is kept under ground in large cisterns, communicating by pipes with the furnaces, and, owing to this method of storage, it is also less exposed to danger from fire. It is established that the cost of naphtha dregs as fuel is about 35 per cent. less than that of wood and coal, and this too at Moscow, which is 1,500 miles distant from the source of supply at Baku, whence naphtha dregs are conveyed by water to Nijni Novgorod, and beyond by rail to Moscow. Several manufacturers of the province of Vladimir have also adopted the new combustible, and the railway lines existing in the Tamboy and Riazan provinces are on the point of doing the same. During 1888, 54,000,000 of pounds (867,857 tons) of naphtha residue were transported from Baku, up the Volga, for use in the interior provinces and in those bordering the Volga. It is expected that in 1889 the supply will exceed 70,000,000 pounds (1,125,000 tons). In the northern zone of the Empire wood will, it must be presumed, hold its own as fuel for some time to come.—*Ibid.*

THE CRISIS IN THE BAKU NAPHTHA TRADE.

Nearly all the railway companies in Russia are using naphtha as a fuel instead of wood or coal, but as its price has gone up very rapidly through the flow becoming less daily the naphtha owners are afraid that the supply will terminate altogether. The Government were asked to send competent engineers to Baku to inspect the mines, and to ascertain how long the naphtha will flow. Accordingly, a civil engineer (Mr. Koushin) inspected the mines, and he has sent a report to the Government advising them to find new fields of naphtha, as the naphtha from the Balakhovskiy mines will eventually cease altogether.—*Ironmonger.*

THE SUPPLY OF RUSSIAN PETROLEUM.

The statement that the oil wells in the Baku district of the Caspian section of Russia are showing symptoms of exhaustion is a matter of considerable importance to all dealers in and users of that class of oil and its products. In Europe—at all events in Western Europe—the Russian oil has never been in really serious competition with the American article, but in the Levant, in Asia Minor, and in India the Russian oil has made great strides, and has secured a strong footing in successful competition with American petroleum. The general progress of the Russian oil is shown by the following figures, which give the production and export in pounds, each pound being a fraction over 36 lb. in weight:—

Years.	Production.	Export.
1884	80,000,000	54,685,429
1885	115,000,000	68,601,310
1886	123,000,000	72,849,104
1887	131,000,000	79,495,123
1888	165,000,000	117,821,020

In India the Russian oil is sold at rather lower prices than the American, and being packed in the same way (in cases of two 4-gallon tins) has made rapid progress, as is demonstrated by the following figures, which represent millions of gallons:—

Years.	American Oil.	Russian Oil.
1880	9½	..
1883	12½	..
1884	26	..
1885	20	..
1886	20	1½
1887	25	5
1888	20	17½

During the first half of this year, however, the exports of American oil to India seem to have increased greatly, the total for the six months being over 20,000,000 gallons from the port of New York alone. Generally speaking, indeed, the exports of American oil have increased this year, as is shown by the subjoined figures, which relate to New York only, and are for the period from January 1 to July 23, 1889:—

Refined Oil.

Destination.	1889.	1888.
	Gallons.	Gallons.
England	23,000,186	21,825,038
Germany	39,188,246	44,087,278
Sweden and Norway	1,962,866	1,527,545
Denmark	889,216	1,570,832
Belgium	11,506,073	16,814,340
Holland	20,260,737	10,972,468
Mediterranean	1,527,030	1,971,080
India	20,281,621	16,791,490
China and Japan	26,632,460	18,331,420
Philippines, Funa Islands, and Straits	26,729,540	15,569,410
Africa	3,627,552	2,015,808
Australasia and Oceania	4,561,067	5,290,816
South America	11,305,252	9,347,676
Rest of America	5,176,269	6,153,902
Totals	196,648,115	172,308,112

Crude Oil.

Destination.	1889.	1888.
	Gallons.	Gallons.
France	16,114,678	11,396,719
Germany	1,288,003	817,022
Rest of Europe	2,807,513	7,862,309
Cuba	1,769,529	1,741,949
Mexico	2,280,644	..
Totals	24,920,367	21,727,999

In addition to this total about 85,000,000 gallons were exported from Boston, Philadelphia, Baltimore, and Perth

Amboy, so that the aggregate exports of American oil have increased by over 13 per cent., comparatively, during the period indicated. If it is true that the Russian supplies are decreasing, it follows that the American oils will be used all over the world in larger quantities than before. The employment of tank steamers is advantageous for the American shippers, and that system can probably be used more economically and more largely by the Americans than by the exporters of the Batoum district.—*Ibid.*

THE RUSSIAN PETROLEUM SUPPLY.

According to the Baku correspondent of the *Chemiker Zeitung* a crisis in the Russian petroleum industry is rapidly approaching, owing to the exhaustion of the springs on the Caspian shore. At the present moment, says the correspondent, the springs are drying up with alarming rapidity, and the new borings yield very little indeed. Nearly all the refineries in Baku, including the large works of the firm of Nobel, are suffering greatly from the want of raw material, the price of which has quintupled within a short time. Occasionally the new borings tap a fresh supply, but all these fresh springs dry up after one or two days. Messrs. Nobel have had to turn to Bibicibat, a place considerably removed from their works, but where the oil is still running freely, for the requisite supply, and the representative of the Rothschild interest at Baku has been suddenly called away to headquarters in Paris to discuss the situation. Besides the Baku region petroleum springs are found all through the Caucasus, but they have never been properly surveyed, and a cessation of the supply at the headquarters of the industry would be little short of a disaster to the whole of the Russian empire.—*Chemist and Druggist.*

THE CANDLE TRADE IN JAPAN.

A Shanghai correspondent says that notwithstanding the increasing consumption of American petroleum in Japan the demand for stearin candles has improved considerably in that country since the year 1885, and during the past year 290,331 cetties were imported, valued at 44,000 yen. The candles imported at present into Japan are mostly obtained from France and Holland, Great Britain's share of the trade being comparatively unimportant. They are nearly always white, and vary in length from seven to nine inches. The weight of the packets is also various, although 12-ounce packets seem to meet with most demand, and the candles are invariably packed in wooden cases containing 25 packets of six candles each. In order to protect the native manufacturers the Japanese Government imposes a duty of nearly $\frac{3}{4}$ yen per picul on all foreign candles.—*Ironmonger.*

BOARD OF TRADE RETURNS.

TWENTY-FIFTH ANNUAL REPORT OF ALKALI, &c. WORKS BY THE CHIEF INSPECTOR. PROCEEDINGS DURING THE YEAR 1888 PRESENTED TO THE LOCAL GOVERNMENT BOARD AND TO THE SECRETARY FOR SCOTLAND. 11d. 1889.

The number of works in England and Ireland registered under the Act at the close of 1888 was 926. In Scotland there were 131, making a total of 1,057 in the United Kingdom. The number of works in 1887 was 1,066, showing a diminution of nine on the whole year.

The following tables show the relative distribution of the various works as regards locality and also with reference to the various processes carried on in them :—

NUMBER OF REGISTERED WORKS.

	Dist. I.—Ireland.	Dist. II.—North of England.	Dist. III.—Cheshire, N. Wales, and part of Lancashire.	Sub-Dist. Widnes.	Dist. IV.—East Lancashire and Yorkshire.	Dist. V.—South Midland.	Dist. Total	62	141	155	71	234	179	160	94	145	1,241	1,245

It will be noticed that the number of works remains almost unchanged, but there appears to be a general tendency for the larger works to increase in size and for the smaller ones to be gradually extinguished.

The total number of visits paid by the various inspectors was 5,101, and the number of tests taken 4,212. There were nine prosecutions undertaken under the Act, in the majority of instances for non-registration.

Various tables of statistics are given relating to the amounts of substances used and of those manufactured, from which the following details are extracted:—

There were 618,582 tons of salt decomposed in the Leblanc process, of which 123,887 tons were taken in District II., 146,640 in District III., and 229,360 in sub-district Widnes. There were, in addition, 37,370 tons consumed in Scotland, giving thus a total of 655,992 for the United Kingdom. Allowing 10 per cent., however, for stoppages, repairs, &c., the above figures become 590,312 tons of salt employed. Besides this, the copper extraction works took for their own requirements 56,750 tons of salt, and there were in addition 212,181 tons of salt decomposed in the ammonia-soda process, showing a grand total of 859,243 tons of salt consumed in 1888.

The total amount of salt manufactured was 2,039,867 tons, of which Cheshire contributed 1,505,667 tons and Staffordshire 6,500.

The total quantity of brimstone burned was only 17,975 tons, whilst the consumption of pyrites approximated very closely to 600,000 tons.

The amount of ammonia produced was equivalent to 122,785 tons of sulphate of ammonia, and this, at 12*l.* per ton, corresponds to a value of 1,473,420*l.* This amount of ammonia was obtained from the following sources, and was at one time entirely wasted:—

AMOUNT OF SULPHATE OF AMMONIA PRODUCED IN THE UNITED KINGDOM.

	1888.	1887.	1886.
	Tons.	Tons.	Tons.
Gas works.....	92,596	85,022	82,480
Iron works	5,280	5,098	3,950
Shale works.....	22,072	21,098	18,080
Coke and carbonising works	2,537	2,678	2,100
Total	122,785	113,896	106,610

One of the most important advances made in the Leblanc process has been that of the recovery of sulphur from alkali waste by Chance's process. The alkali waste contains from 11 to 15 per cent. of sulphur, and some 750,000 tons of it are produced annually, containing about 100,000 tons of sulphur. By this process about 90 per cent. of the total sulphur present in the waste is recovered as sulphuretted hydrogen, and of this from 80 to 85 per cent. of sulphur can be obtained in the solid form, or from 98 to 99 per cent. as sulphuric acid. It seems likely, further, that as the knowledge and skill with which the process is manipulated increases, so a still greater percentage of the sulphur may be recovered. Another process to which reference is made is that of Gossage, of Widnes. In this process sulphate of soda, mixed with about 30 per cent. of salt, is heated with slack, and thus reduced to the sulphide. The mass is lixiviated with water, and carbon dioxide gas is passed in with the evolution of sulphuretted hydrogen gas, which is employed in the manufacture of more sulphuric acid, and with the formation and precipitation of bicarbonate of soda from the solution. Salt is mixed with the sulphate both because it increases the fusibility of the mixture, and also because it lessens the action of the sulphide on the ordinary black-ash furnace which it is probable will be used.

Various methods for dealing with sulphuretted hydrogen gas have been proposed at different times, such as burning in a special fire, burning to form sulphuric acid, burning in a Claus kiln, with the formation of sulphur, or absorbing with hydrated peroxide of iron. The more usual methods are modifications of the last of three plans.

The oxide of iron employed is usually either dry or in a slightly damp condition, but Mr. G. E. Davis has used it suspended in water which seems to answer well, but a steam jet must then be employed to force the gases onward.

Very full tables are given of the works which make ammonium sulphate, and of the arrangements which they adopt for preventing the escape of sulphuretted hydrogen during the manufacture. The greatest amount made in the 24 hours was 40 cwt. and the least 1½ cwt. The superficial area of the purifier varied from as much as 532 sq. ft. to 4½ sq. ft. The depth of the oxide varied from 5½ ft. to half a foot in depth. The number of cubic feet of oxide per cwt. of salt produced in 24 hours varied from 200 in the highest to 1 in the lowest case. The oxide was found to remain

active from 180 days in one works to only 2 days in another plant. In some places it is only removed four times in the year, though in these cases the process is worked only intermittently. The oxide is re-vivified either in situ or by being turned out and exposed to the air. Very varied forms of apparatus are used for condensing the steam from the sulphuretted hydrogen gas, water or air cooled pipes or coke towers being on the whole the most suitable. A prominent feature in the report is the series of analyses of chimney gases given when smoky, slightly smoky, and clear. It had been stated, and even pleaded in a court of law, that if the gases were clear, that then probably carbon monoxide gas would be present, and hence that the presence of the black coal smoke was by no means an unmitigated evil, inasmuch as none of the former poisonous gas would then be present. As was to be expected, it is shown that in no single case, out of some 50 analyses made of the products of combustion from both hand-fired furnaces and mechanical stokers, was there a trace of carbon monoxide present where the gases were completely clear, whilst where there was black smoke as much as 3.25 per cent. CO was on one occasion found. Comparing the general results obtained with solid and gaseous fuel, attention is drawn to the much more favourable results obtained with the latter, and points out how much easier it is to exactly regulate the supply of air, so that there shall not be an excess of oxygen, and hence also of nitrogen, on the one hand, nor unburnt carbon on the other. Other advantages are that the gas burns quietly and regularly without waste of any kind, and that there is no smoke or soot, and, further, owing to the more equal distribution of the heat, the action on the metal boilers is much reduced. In this connexion is mentioned Mond's process for obtaining the ammonia produced in carbonising the coal, and which by other methods is lost, and the amount thus obtained averages about 66 lb. of sulphate per ton of slack carbonised.

After the report of the chief inspector come the separate reports of each district inspector, and the chief features in these are given briefly. In all cases statements are given as to the number of works under inspection, and of the various processes therein carried on, average analyses of chamber exit gases, chimney gases, &c., and of the various improvements effected in the plant at different works.

In District No. 1 (Ireland) there are 44 works, only two of which are alkali; the number of separate manufacturing processes carried on being 59. During the year 7,446 tons salt were decomposed, 2,832 tons bleaching powder produced, 22,700 tons pyrites, and 180 tons brimstone burned, 43,200 tons chemical manure, 2,508 tons sulphate of ammonia, and 9,700 tons salt manufactured.

In District No. 2 (North of England) the inspector reports that the average total acidity of manure gases at the exit was 0.124, the average of the three preceding years being 0.160. In the Widness sub-district 30 works were registered, 18 of these being alkali. During the year there were 149,000 tons of pyrites burnt, 229,360 tons of salt converted into salt-cake, and 203,000 tons used in the wet copper extraction works, and 72,930 tons of bleaching powder manufactured (including potassium chlorate). Attention is drawn to a valuable improvement in the Weldon plant, whereby the acid liquors are completely neutralised in the stills themselves by the addition of more Weldon mud. Hence the special neutralising well is no longer necessary, and besides the saving of the limestone therein employed, the amount of the base in the mud is reduced so that a ton of bleaching powder can be made from about 45 cwt. of salt instead of requiring about 50 cwt. In most of the works no bleaching powder chamber is now opened if it contains more than 5 grains of chlorine per cubic foot of its atmosphere.

Usually not more than half this amount is present. For the purpose of absorbing the residual chlorine Brock and Minton's lime-sprinkling machine has been found very efficacious, and at the works of the patentees some 200 tons of bleach have been obtained by its means from lime injected into the finished chambers. Some new methods for obtaining chlorine direct from hydrochloric acid by the action of this latter on nitric acid are given. The nitrous oxides

simultaneously produced are recovered, and re-converted into nitric acid, and this is again decomposed as before.

In District No. 4 (East Lancashire and Yorkshire) the lime-dusting machine has also been used with beneficial results, both as to the increase in the manufacture, and as to the diminution of nuisance in packing. The average test for the chamber exits for 1888 was 1.04 grains SO_3 per cubic foot as compared with 1.14 in 1887. For the first time the average escape from vitriol works, other than alkali works, has been less than in the alkali works themselves, being 1.01 grains SO_3 per cubic foot, the average escape from the latter being 1.07 grains SO_3 per cubic foot. Some results are given as to the behaviour of the Claus kiln in the works using it. Experience has shown that both SH_2 and SO_2 leave the sulphur depositing chamber in greater or lesser quantity, and that to remove the latter an alkaline wash tower should be employed, and for the former a final catch purifier. More SH_2 than SO_2 is usually present in the escape, thus an actual example shows:—
Total S = 3.25 grains per cubic foot, S as SO_2 found = 0.13 grains, S as SH_2 by difference = 3.12 grains per cubic foot. Some 100 tons of sulphur were recovered during the year in this way.

In District No. 6 (South-West of England and South Wales) 132 works with 160 separate processes under inspection were registered. There are 42 works where sulphuric acid is manufactured. The sources of sulphur are various, pyrites (Spanish, Norwegian, and Cornish), coppers, sulphuretted hydrogen, and brimstone having been all employed. The largest source was pyrites, but 7,626 tons of brimstone were burnt. In one works where there was considerable difficulty in disposing of the gas liquor, a plant capable of turning out 50 tons of sulphate of ammonia per annum was put up for less than 100*l*. A coke scrubber was used for the condensation of the steam, and the purifier was a heap of oxide of iron, below which the SH_2 was introduced by an ordinary iron pipe terminating in four channels of loosely arranged bricks. This very simple form of purifier seems to work well and has been generally adopted in other works.

In Sub-district No. 7 (Eastern Counties) the average chamber exit escape for 1888 was 1.55 grains SO_3 per cubic foot, the average in 1887 being 1.97 grains SO_3 per cubic foot. In one works, owing to insufficient pound space and also to the cost of the water required for condensing purposes, a considerable escape was found to exist. To meet these requirements the following form of condenser was devised. It consists of an outer lead-lined shallow vessel, 11 ft. 6 in. by 6 ft. 3 in. by 1 ft. 6 in., nearly filled with water. Within this is placed a wooden chamber 10 ft. 6 in. \times 5 \times 5 in which the water is at the same level as in the outer vessel, and passing through the axis of which is a wooden shaft carrying paddles in two sets, the one set being attached transversely to the shaft, the other set longitudinally, and both plunging beneath the surface of the water. The paddles are further kept moistened by means of a perforated pipe running the length of the outer vessel through which the water falls in a shower on the revolving paddles below. By suitable divisions the gases are carried through the apparatus in definite directions. A steam jet is also inserted in the inlet pipe and has been found to be a very useful adjunct to the apparatus. The efficiency of this condenser is shown by the following test analyses:—

Total acidity of gases entering revolver (1)	20.0 grains at SO_3
" " " (2)	23.4 " "
Total acidity of gases leaving revolver (1)	1.45 " "
" " " (2)	0.85 " "

(Excellent scale plan drawings, for which the report itself must be consulted, are given.)

A separate report is issued for Scotland. The number of registered works was 131, of which 16 were alkali works, the total number of processes carried on being 180, thus showing a reduction of eight works and 18 processes as compared with the similar figures for 1887. The number of

visits made was 467, and 227 analyses were made. The amounts of material employed and manufactured were as follows:—

Employed....	Salt	45,094	(37,370 in alkali works, 7,724 in wet copper works.
	Pyrites.....	72,248	
	Sulphur.....	3,982	
Manufactured	Bleach	10,300	
	Chemical manure	43,585	
	Ammonium sulphate.	36,831	9,829 from gas liquor. 4,550 iron furnace gases. 22,072 from shale works.
	Salt.....	10,900	
	Nitric acid.....	2,331	

The average escape of HCl for the whole of Scotland is 0.088 grains HCl per cubic foot of chimney gases, as against 0.09 grains in 1887. The whole of the sulphate of ammonia is produced from what at one time were waste products, and the value of the material thus saved to the county amounts to 441,972*l.*, taking one ton of sulphate of ammonia as being worth 12*l.* The sulphuretted hydrogen given off in the manufacture of the sulphate or chloride of ammonia is now absorbed by hydrated oxide of iron in 13 out of the 22 works manufacturing these articles. As in last year's report, so in this, reference is made to the anomalous wording of the Act by virtue of which some works come under inspection, whilst others, to the full as bad, in some cases worse, do not come under its provisions. It is again proposed not to schedule the processes to be inspected, but to extend inspection over the noxious gases evolved in the processes of manufacture. It would then be sufficient to draft a short Act, called the Noxious Gases Act, in which it would be sufficient to include the following substances:—"The acid compounds of chlorine, fluorine, sulphur, and nitrogen, chlorine and metallic fumes."

—S. G. R.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

11,350. R. C. Garton, C. H. Garton, and W. Lawrence. Apparatus for evaporating, heating, or cooling liquids. July 15.

11,352. R. C. Garton, C. H. Garton, and W. Lawrence. Apparatus for evaporating or distilling, or effecting interchange of heat. July 15.

11,402. E. Bazin. Hydro-centrifugal apparatus for washing, amalgamating, and separating metallic ores, and for washing and separating other bodies of different densities. July 16.

11,466. H. H. Chapman.—From J. Donaldson, Australia. Automatic attachment for indicating pressures and levels of fluids and liquids in vessels. Complete Specification. July 17.

11,518. A. T. Clarksen and J. B. Spurge. Duplex and other apparatus for regulating the flow of gases under pressure. July 18.

11,600. A. G. Brown. Apparatus for separating water from steam. July 20.

11,691. E. Breadner. Humidifiers. July 23.

11,865. L. Perkins. Refrigerating and freezing apparatus. July 25.

11,925. C. A. Rempen and E. Andre. Valves for regulating the pressure of gas and other fluids. July 26.

12,206. W. Tipping. Machines for "distructing," drying, and calcining substances or materials. August 1.

12,207. W. Tipping. Apparatus for moistening atmosphere, damping materials or substances, and condensing vapours, or analogous purposes. August 1.

12,410. W. L. Wise.—From P. R. Bedlington, Grand Canary. Apparatus for measuring and indicating temperature and pressure. August 6.

12,473. H. B. Whetstone. Evaporating or distilling liquids, and drying or desiccating grain or other substances. August 6.

12,514. J. V. Johnson.—From La Compagnie Industrielle des Procédés Raoul Pictet, France. An improved mixture for use in apparatus for producing cold. Complete Specification. August 8.

12,636. C. W. Guy. Apparatus for evaporation and condensation. August 10.

12,681. L. Hill. Improvements in the means employed for utilising the escaping hot gases or products of combustion for heating the air supplied to the furnaces of steam boilers. August 12.

12,716. W. Matthews and J. Yates. Apparatus for humidifying air, pulverising fluids, and other similar purposes. August 12.

12,789. H. H. Lake.—From F. du Closel, France. Apparatus for extracting soluble from insoluble substances, and for filtering liquids. August 12.

12,834. W. Gordon. Gauges for indicating the level of water and other fluids in steam generators and analogous vessels. August 14.

12,835. W. Gordon. Gauges for indicating the pressure of fluids. August 14.

12,871. C. H. Roeckner, F. L. Roeckner, and R. L. Roeckner. Concentrating liquids, and burning off organic matter. August 15.

12,885. M. Miller. Steam or air superheater. August 15.

12,911. J. T. Griffin.—From J. W. Hatch, United States. Improvement in furnaces, apparatus to be used therewith, and in utilising solid and gaseous fuel therein. August 15.

12,973. The Water Softening Company, Limited, E. Easton, and H. Carrod. Apparatus for softening and filtering water or other liquids under pressure. August 16.

12,809. W. Maxwell. See Class XVI.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

10,493. T. Slater. Multiple evaporating apparatus. July 24.

14,063. J. S. Fairfax. Metallic vessels for containing and supplying fluids under pressure. August 21.

14,394. W. G. Forster. Furnaces, &c. for heating pots and crucibles. August 21.

14,616. M. Heeking. Centrifugal pumps. July 24.

15,491. L. Serpollet. Pulverising, dividing, or gasifying liquids. July 24.

1889.

8898. W. B. Wright. See Class II.

9204. J. E. Warren. Apparatus for filtering. August 14.

10,423. J. V. Davis. Hydrometers, and apparatus connected therewith. August 7.

10,686. H. J. Haddan.—From J. P. y Rodereda and E. P. y Rodriguez. Machinery for triturating and crushing substances. August 7.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

11,432. C. McKenzie Dowie and A. L. Briggs. Improvements in apparatus for carburetting illuminating and other gas. July 17.

11,456. N. Meiklejohn. Improvements in anti-dips for hydraulic mains employed in the manufacture of gas. July 17.

11,459. J. Dheyne, Comte de Nydprück, and F. de la Hault. Improved apparatus for generating gas or vapour from combustible liquids. July 17.

11,462. J. Gilligan and A. Tilney. Improvements in apparatus for perfecting combustion and preventing smoke in house grates and other open fires. July 17.

11,463. J. G. Forge and A. Tilney. Improved methods of heating and apparatus therefor. July 17.

11,521. J. H. Glew. Improved compound or admixture of ingredients for the production of fire-lighters. July 18.

11,530. J. Enwright. Improvements in the manufacture of "water-gas" and of coal gas. July 19.

11,610. W. Hubbard. Improvements in the manufacture of compressed fuel blocks. Complete Specification. July 20.

11,624. F. J. Jones. Improvements in the manufacture of illuminating gas. July 20.

11,654. J. Drabble. An improved apparatus for the prevention and consumption of smoke, and more perfect combustion of fuel in steam boilers and other furnaces. July 22.

11,768. O. Rose. Improvements in apparatus for the manufacture of gas from hydrocarbon oil and water. July 24.

11,855. J. Morris. The manufacture of an improved artificial fuel. July 25.

11,899. C. Huelser.—From G. Kassner, Germany. Process for converting the oxygen of the atmosphere into a solid form by producing plumbate of lime, baryta, and strontia, and employing these substances for producing oxygen and for oxidising purposes. Complete Specification. July 26.

11,920. F. J. Jones. Improvements in the production of coke for foundry and other purposes. July 26.

12,043. J. F. L. Moniër. Improvements in or relating to the manufacture of gas from atmospheric air. July 29.

12,054. B. H. Thwaite. Improved method of distributing heating and lighting gas. July 30.

12,092. A. Weber. Improvements in coke ovens or furnaces. Complete Specification. July 30.

12,149. B. H. Thwaite. Improvements in the cycle of operations for producing combustible gases from hydrocarbonaceous materials, and in details of apparatus therefor. July 31.

12,266. B. H. Thwaite. Improvements in methods for effecting the operations involved in the production of the gas technically known as "water-gas," and in apparatus therefor. August 2.

12,296. A. Degallier. An improved system of economical heating apparatus. August 2.

12,460. S. Elliott. An improved method of and apparatus for the treatment of smoke. August 6.

12,584. R. R. Main, A. P. Main, and H. Darwin. Improvements in gas fires. Complete Specification. August 9.

12,655. J. Watson. Improvements in heating apparatus. August 10.

12,856. J. O. Spong. Improved means and appliances for carburetting gas and enriching the flame thereof. August 14.

12,897. R. Henderson. Improvements in the manufacture of tapers, torches, matches, and candles. August 15.

13,016. J. Dewar and B. Redwood. Improvements in the distillation of mineral oils and like products, and apparatus for that purpose. August 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8559. The Gas Patents Syndicate.—From J. B. Areher. Apparatus for the manufacture of gas. August 14.

13,050. O. Langberg. Apparatus for generating illuminating gas and gaseous fuel, and for burning the latter. August 21.

13,066. T. L. J. Quennesson. Manufacture of artificial fuel and other moulded blocks, and apparatus therefor. July 31.

13,768. R. Stone. Manufacture of artificial fuel and refractory material for lining retorts, and apparatus therefor. August 21.

14,510. J. de Brouwer. Apparatus for the manufacture of gas. August 14.

14,575. H. H. Leigh.—From T. von Bauer. Coke ovens. August 14.

14,675. H. D. Fitzpatrick and G. Rose. Manufacturing gas from mineral or other oils, and apparatus therefor. August 14.

1889.

2246. G. H. Lloyd, A. L. Lloyd, H. Bewlay, and W. S. Sutherland. Producing water-gas, and apparatus therefor. July 31.

6130. S. Fox and E. Blass. Method and apparatus for adding volatile substances to gases. August 21.

6805. L. Paget and C. J. Kintner. Hoods or mantles for incandescence gas-lighting. July 31.

6854. H. W. Leonard. Means for feeding fluid fuel to furnaces. July 17.

8898. W. B. Wright. Means for feeding fluid fuel to furnaces, specially applicable to brick kilns. August 21.

9288. W. Clark. Apparatus for manufacturing gas. July 24.

10,101. W. J. Pughley. Manufacture of fuel. July 24.

10,256. A. J. Boulton.—From W. G. Wood. Manufacturing gas. July 31.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

12,028. J. D. Starck. See Class VII.

12,526. A. Patrick. See Class IX.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

11,613. O. Imray.—From The Society of Chemical Industry, Basle. Manufacture of new red and blue colouring matters. July 20.

11,666. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brüning, Germany. Improvements in the production of an orange-red colouring matter from flavopurpurin. July 22.

11,795. H. H. Leigh.—From R. G. Williams, United States. Improvements in colouring matters. July 24.

11,848. O. Imray.—From The Society of Chemical Industry, Basle. Manufacture of blue colouring matter. July 25.

12,031. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brüning, Germany. An improved manufacture of compounds for dyeing, consisting of a mixture of nitrite with basic amido-azo-compounds, or with the nitro compounds of aromatic monamines in the form of a paste, and the application of such paste for diazotising. July 29.

12,191. C. Kolbe. A process for obtaining carbon acids of meta-amido-phenol and its alkyl derivatives. August 1.

12,334. J. Dawson. Manufacture of a new base for colouring matters. August 3.

12,549. T. R. Shillito.—From A. Feer, Germany. Process for the manufacture of yellow to orange colouring matters. August 8.

12,560. S. Pitt.—From L. Casella and Co., Germany. Production of new red colouring matters. August 8.

12,567. E. M. Richford and J. Brown. An improvement in the preparation of colouring matters. August 8.

12,767. H. H. Leigh.—From R. G. Williams, United States. Improvements in the manufacture of mixed azo colours. August 13.

12,768. R. Holliday. Improvements in the manufacture or production of new azo colours. August 13.

12,784. O. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. Manufacture of colouring matters derived from paratoluidine, α -metaxyldine, pseudo-cumidine, and mesidine, with tetramethyldiamidobenzhydrol. August 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,767. T. R. Shillito.—From J. R. Geigy. Production of new colours. July 31.

13,920. T. R. Shillito.—From J. R. Geigy. Production of yellow, orange, and brown colours of alizarin-like properties. July 24.

14,353. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. A new class of derivatives of alizarin-blue. August 14.

14,442. B. Wilcox.—From the Farbenfabriken vorm. F. Bayer and Co. Azo dyestuffs. August 14.

14,478. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Production of a colouring matter from carbazol. August 14.

14,479. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The production from carbazol of a new derivative, to be used in the manufacture of colouring matters. August 14.

14,884. G. Pitt.—From L. Casella and Co. New yellow dyestuffs called thioflavines. August 14.

15,179. E. Fischer. Production and treatment of oxidisable derivatives of ortho-nitro-benzylchlorides. August 21.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

11,549. F. N. B. Rosslyn, R. Rice, and A. T. Haines. See Class XIV.

12,626. G. W. Robertson, D. Black, and J. McGlashan. Improvements in the treatment of vegetable fibrous material to obtain fibre therefrom, and in apparatus therefor. August 9.

12,975. A. Deru. Process of and apparatus for automatically drying and purifying wool and other textile materials. August 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,100. L. de Kien. Process and apparatus for treatment of textile plants. August 7.

14,247. I. Singer and M. W. Judell. Apparatus for cleansing wool, &c. August 7.

14,705. E. P. Khug. Process for smoking or finishing textile threads. August 14.

1889.

6793. The Société Simons and Chapuis. Machine for drying and carbonising wool, &c., in combination with an elevator and purifying apparatus. August 21.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

11,382. G. B. Sharples. Improvements in machinery for the continuous bleaching, soaping, bluing, washing, finishing, sizing, dyeing, or otherwise analogously treating in the hank, of cotton, linen, woollen, silk, or other yarns, tapes, and similar manufactures. July 16.

11,938. R. Leigh. Improvements in sizes and methods for fixing colours in printing, painting, and staining paper, cloth, &c. July 27.

12,990. E. Barlow. A dyers' colour mixer. August 17.

COMPLETE SPECIFICATION ACCEPTED.

1888.

14,019. S. Mason, jun., and W. T. Whitehead. Machines for dyeing, bleaching, &c., yarns in cops or bobbins. August 7.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

11,351. R. C. Garton, C. H. Garton, and W. Lawrence. Improvements in the crystallisation of salts or crystallisable acids. July 15.

11,975. E. Augé. Improvements in the manufacture of soda alum. July 27.

12,028. J. D. Starek. Process and apparatus for the production of fuming sulphuric acid or of sulphuric anhydride from the acid waste or residual matter obtained in the petroleum, paraffin, and tar industry. July 29.

12,368. A. Brand. Improvements in the manufacture of alkali sulphides. August 3.

12,451. A. W. Wahlenberg and J. A. Wahlenberg. An improved process of producing ammonium nitrate. Complete Specification. Date applied for February 9, 1889, being date of application in Sweden.

12,464. J. B. Thompson. Improvements in the manufacture of soda and in the recovery of the material used in the process. August 6.

12,553. F. Candy. Improvements in the treatment and utilisation of certain products resulting from the purification of galvanisers' spent pickle and tinplate workers' waste or spent liquors, and other like waste or spent liquors. August 8.

12,843. W. Donald. Improvements in and relating to the treatment of common salt or other suitable chlorides for the manufacture of chlorine and recovery of the manganese. August 14.

12,948. G. Kerner and J. Marx. Improvements in, and apparatus for or connected with, the obtaining, liquefying, and storage of chlorine. August 16.

13,003. A. W. Ellis. Improvements in the treatment and distillation of ammoniacal liquor of gas and other works, and in the manufacture of sulphate of ammonia therefrom, and in the apparatus to be employed therein, and for the prevention of nuisance in such manufacture. August 17.

13,017. O. Imray.—From V. G. Bloede, United States. Process for the recovery of soda or potash from waste alkaline lyes. August 17.

13,018. O. Imray.—From V. G. Bloede, United States. Utilisation of waste or spent alkaline liquors. August 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

11,581. D. Gamble. Manufacture of chlorine and hydrochloric acid, and apparatus therefor. August 14.

11,926. W. E. B. Blekinsopp and F. M. Lyte. Production of basic lead carbonate, chloride, phosphate, oxalate, silicate, borate, or other insoluble or sparingly soluble salts of lead. July 24.

13,306. W. P. Thompson.—From W. Spilker and C. Loewe. Manufacture of soda, potash, and "ehlore." July 24.

14,026. R. H. Steedman. Treating impure carbonate of lime produced in making alkali, and recovering sulphur from alkali waste in order to utilise it for making cement, &c. August 14.

14,199. T. Parker and A. E. Robinson. Manufacture of chlorine, alkalis, and salts from the chlorides of sodium and potassium. August 7.

14,239. J. Greenwood. Generation of chlorine and formation of a solution therefrom, and apparatus therefor. August 7.

14,563. G. H. Bolton and T. A. Bullough. Washing, filtering, and otherwise treating lime, mud, black-ash, &c. in bulk, and apparatus therefor. August 14.

15,293. P. McLaren. Manufacturing acetate or pyro-lignite of iron or iron liquor. July 24.

16,523. W. Townsend. Vessels for boiling or evaporating acids or strong alkalis. July 31.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

11,690. M. Pommard. Improvements in the manufacture of flower vases, pots, or analogous receptacles. July 23.

11,839. W. Worrall. Improvements in printing on china, earthenware, glass, and other like substances. July 25.

11,945. H. C. Harrison. Improvements in the manufacture of earthenware toilet ware. 27 July.

11,979. H. H. Lake.—From A. Glibert, Belgium. Improvements relating to the enamelling of articles of copper. July 27.

12,158. T. Walton. Improvements in the manufacture of various kinds of glassware, and in machinery, apparatus, or moulds therefor. July 31.

12,362. J. Wade and J. Gosling. New or improved machinery for the manufacture of earthenware covers having knobs for teapots, jugs, dishes, and other vessels and articles. August 3.

12,923. J. Nash. Improvements in the manufacture of porous earthenware. August 15.

12,980. J. Nash. An improved process for hardening, preserving, and preparing porous earthenware. August 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

11,651. J. Armstrong. Method of making bottles, &c., and appliances therefor. July 24.

11,794. J. Armstrong. Method of making rolled glass and appliances therefor. August 14.

12,679. M. Green. Producing letters for cementing to glass, &c., in imitation of gold, silver, and jewels. July 24.

13,259. W. R. Pullen. Mosaic work in crystalline glass alone, or in combination with vitreous substances. July 24.

13,765. P. J. Guy. Dispensing with woad clay in plying and firing glaze ware. July 31.

14,466. S. Washington. Glass bottles. August 14.

14,644. J. Hamblet. Machinery for the manufacture of seggars, crucibles, melting-pots, pipes, &c., from clay or other plastic material. July 24.

14,830. W. M. Derrick. Method for the ornamentation of glass. August 21.

1889.

9979. E. Leak and H. Aynsley. Grooved shields for supporting potteryware while firing. July 24.

10,322. W. Lutwyche. Manufacture of translucent enamel, and application thereof in relief for the decoration of glass, metal, &c. August 7.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

11,385. R. R. Gibbs. Improvements in the manufacture of bricks and blocks. July 16.

11,444. M. J. Adams. Improvements in roofing tiles, and in the formation of iron and other sheets or plates for roofing and other purposes. Complete Specification. July 17.

11,663. J. W. Breakell and T. Breakell. Improvements in colouring and polishing calcareous and other stones. July 22.

11,922. G. F. Redfern.—From J. G. Maardt, Denmark. An improved composition for covering walls and the like. Complete Specification. July 26.

12,369. A. Brand. Improvements in the manufacture or treatment of fire-bricks, furnace-linings, crucibles, and the like. August 3.

12,526. A. Patrick. Improvements in the treatment of shales or other carbonaceous minerals for the manufacture of bricks and for the obtainment of condensable products, and in apparatus therefor. August 8.

12,550. M. J. Dickins. Improvements in road paving. August 8.

12,623. T. Shaw. Improvements in utilising the waste product from sewage works for building and other purposes. Complete Specification. August 10.

12,665. R. Haddan.—From W. Martin, Switzerland. A waterproof material for covering or ornamenting walls and other structures. August 10.

12,889. T. Smith and R. B. Wager-Taylor. An improved process for and method of manufacturing cement or artificial stone. August 15.

12,890. T. Smith and R. B. Wager-Taylor. An improved cement or artificial stone. August 15.

13,008. J. Wilson. Improvements in or relating to the construction of fire-resisting flooring, decking, and the like. August 17.

COMPLETE SPECIFICATION ACCEPTED.

1889.

9927. H. H. Lake.—From C. T. Lee. Compound for manufacture of articles by moulding. July 24.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

11,344. C. F. Jozs. Improvements in the manufacture of ornamental plates of metal or other sheets. July 15.

11,393. T. Parker. Improvements in and connected with the manufacture of iron and steel. July 16.

11,402. E. Bazin. See Class I. July 16.

11,406. E. Norton and J. G. Hodgson. Improvements in apparatus for use in the manufacture of sheet metal. Complete Specification. July 16.

11,407. E. Norton and J. G. Hodgson. Improvements in the manufacture of metal bars or rails, and in apparatus therefor. Complete Specification. July 16.

11,686. C. U. Fisher.—From H. F. Lord, United States. A new or improved welding compound. Complete Specification. July 23.

11,707. T. Parker and A. E. Robinson. Improvements in the manufacture of sodium, potassium, and magnesium. July 23.

11,788. D. Dennes.—Partly communicated by T. K. Rose, Denver, U.S.A. Improvements in obtaining precious metals from their ores, and in means or apparatus employed therein. July 24.

11,790. F. A. Kieffer. Improvements relating to the extraction of copper from its ores. July 24.

11,882. S. Trivick. Improvements in roasting certain ores in order to obtain metals therefrom, and in means or apparatus employed therein. July 26.

11,883. S. Trivick. Improvements in extracting precious metals from their ores, and in means or apparatus employed therein. July 26.

11,888. J. Potts. Improvements in or relating to the manufacture or treatment of material for the construction of guns, and for other purposes. July 26.

12,033. H. Bessemer, jun. Improvements in the production of aluminium, and in apparatus employed for that purpose. July 29.

12,113. C. L. Bath. Improvements in apparatus for forming copper ingots. July 30.

12,166. W. Ambler. Improvements in the manufacture of steel and other metal sheets and plates. July 31.

12,167. W. Ambler. Improvements in the manufacture of rolls, castings for guns and shafts, and other solid metal castings. July 31.

12,181. E. Guillemin-Tarayre. An improved method of working, preparing, and concentrating auriferous alluvium. July 31.

12,216. J. P. E. C. Stromeyer. A steel alloy for ship or boiler plates. August 1.

12,217. J. P. E. C. Stromeyer. A cast steel alloy for resisting the corrosive action of sea water. August 1.

12,315. G. Kamenisky. An improved process of refining gold. August 2.

12,322. F. L. Bartlett. Improvements relating to the treatment of ores containing lead, zinc, and other metals. Complete Specification. August 2.

12,500. T. Twynam. Improvements in the manufacture of ingot iron and steel. August 6.

12,556. W. P. Thompson.—From A. A. L. Levy, France. Improvements in coating or plating metal plates or articles of large or small size. August 8.

12,648. J. Clark. Improvements in obtaining alloys of aluminium with other metals. August 10.

12,649. D. Colville, jun. Improvements in arrangements and apparatus for charging materials into steel making or melting furnaces. August 10.

12,811. T. Hydes and S. W. Wilkinson. Improvements in apparatus for casting automatically molten metal, slag, and other molten material into pigs, blocks, or other like forms. August 14.

12,839. J. C. Bromfield. Improvements in or connected with the manufacture of iron and steel, and in the utilisation thereof of waste products. August 14.

12,945. H. E. Cooper. An improved method of moulding and casting metals. August 16.

13,013. N. M. de la E. Tenison-Woods. Improvements in precipitating metallic tin from solutions of oxides of tin in alkaline mediums, and separating any other metal soluble in the same alkaline solutions. Complete Specification. August 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

6326. A. G. Greenway. Manufacture of iron. July 31.

11,399. C. T. J. Vautin. Extracting gold from auriferous ores. August 7.

11,851. J. G. Thomas and G. H. White. Apparatus for coating metal sheets with tin, terne, or alloys. July 24.

12,626. H. W. Wallis. Manufacture of sodium and potassium. July 31.

12,982. C. F. Cockshott and J. E. Jowett. Method and apparatus for obviating pinholes and sponginess in cast brass or gun-metal shells, &c. July 31.

13,516. J. Frankland and W. H. Summerscales. Apparatus for forming sand cores for moulding purposes. July 31.

13,624. H. S. Maxim. Tempering and toughening ordnance, and apparatus therefor. August 21.

13,742. H. Eckardt. Alloys. July 24.

13,745. J. L. Walker. Construction of sheet metal hollow-ware. July 31.

13,843. H. J. Smith. Manufacture of steel and iron. July 31.

14,150. H. Schneider. Manufacture of alloys of steel and nickel. August 7.

14,240. J. Greenwood. Extraction of gold from refractory and other ores, and apparatus therefor. August 7.

14,299. J. Harris-James. Separating ores from the associated gangue. August 14.

14,397. J. G. Landstrom. Process and apparatus for enriching and separating ores. August 21.

14,517. W. A. McCool. Drawing metals, and apparatus therefor. August 14.

14,807. E. Brazier and J. Thompson. Method and apparatus for coating metal plates with tin, terne, or lead. August 21.

15,101. C. N. B. Wetzlar.—From W. L. Card. Dry concentrators for the treatment of ores. July 31.

16,231. J. Hilton. Cupolas, and means for operating same. July 24.

18,440. C. A. Burghardt. Production of pure zinc. August 21.

1889.

336. E. Britton. "Box piles" for converting iron or steel scrap into bar or plate. July 31.

345. C. N. B. Wetzlar.—From W. L. Card. Portable prospecting machine for use in mining and working on the dry process. July 31.

659. C. A. Burghardt. Reduction of zinc and tin from their ores. August 21.

3149. A. J. Boulton.—From W. G. Clark. Coating metals. August 21.

3916. D. I. Reisz, M. Berkovits, and J. Biehler. Metallic alloy for syphon heads, &c., and for tuning purposes generally. August 7.

5980. P. Schroedter and A. Schroedter. Purifying quicksilver. July 31.

7353. N. Lébédoff. Apparatus for extraction of metals from ores. August 7.

9206. J. T. King.—From W. R. Jones. Manufacture of iron and steel, and apparatus therefor. July 24.

9646. A. J. Boulton.—From J. M. Durafor and V. E. J. Durafor. Manufacture of articles in cast metal, with a coating of other metal. July 31.

11,407. E. Norton and J. G. Hodgson. See Application above. August 21.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

11,471. E. N. Reynier. Improvements in electric accumulators or storage batteries. July 17.

11,528. C. Beyer and G. Hagen. Improvements in electrode plates for electric accumulators. July 19.

11,590. F. King and W. P. Mendham. Improvements in primary batteries. July 20.

11,661. C. Huelser.—From H. Mestern, Germany. Improvements in thermo-electric and furnace batteries. July 22.

11,780. C. E. Buell. Improvements in electric generators. Complete Specification. July 24.

11,914. A. Reckenzaun. Improvements in the manufacture of plate for secondary voltaic batteries. July 26.

11,962. P. Naef. Improvements in or appertaining to the manufacture of peroxide of lead or alkaline plumbate and by-products. July 27.

12,145. P. M. Justice.—From E. G. Acheson, United States. Improvements in generating electricity or magnetism by the application of heat. Complete Specification. July 31.

12,402. W. P. Kookogey. A galvanic battery solution. Complete Specification. August 6.

12,474. H. W. Bishop and F. Brown. The inlaying of metals by electro deposition. August 6.

12,503. F. V. Andersen. Improvements in dynamo-electric machines. August 6.

12,731. W. P. Kookogey. A plate for secondary batteries. August 13.

12,752. H. G. Morris and P. G. Salom. Improvements in machines for filling secondary battery plates. Complete Specification. August 13.

12,772. A. de Castro. Improvements in means or apparatus for the generation and conversion of electric energy. August 13.

12,799. A. H. Chesnier and F. B. A. R. de la Bastie. Improvements in single fluid batteries. August 13.

12,906. E. Hermite, E. J. Paterson, and C. F. Cooper. Electrolytic treatment of vegetable matters and cereals for the production of starch. August 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,290. A. Schanschieff. Galvanic batteries. July 31.

13,402. S. A. Varley. Secondary batteries. July 24.

14,149. B. Willecox.—From C. S. Bradley. Dynamo-electric machines. July 31.

1889.

2297. C. Smith.—From W. L. F. Hellesen. Primary and secondary transportable galvanic dry elements. July 31.

8552. G. Nahusen. Electrolytic separation of aluminium, aluminium alloys, and magnesium from solutions of their salts. August 7.

8855. T. Harris and H. F. de Bathe Cameron. Secondary batteries. August 21.

9153. D. J. Arnold and H. B. Coryell. Dry galvanic battery. August 7.

9994. E. Maigrot and J. Sabates. See Class XVI.

10,889. E. M. H. Andreoli. Electrolytic production of hypochlorite of sodium. August 14.

11,044. W. P. Thompson.—From P. H. Alexander. Storage batteries. August 14.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

11,383. C. Lahsen and C. Feuerlein, Liverpool. Method of extracting pure neutral grease from wool or the like. July 16.

11,660. H. Schuster. Process for producing hard soap from vegetable or animal fats, or a mixture thereof, and caustic alkaline solutions, without employing carbonate of alkalis or chloride of sodium. Complete Specification. July 22.

11,817. C. R. Huxley. Ammoniated soaps. July 25.

12,259. E. Howell. Japanese magic soap for cleaning and polishing all kinds of furniture, painted woodwork, glass, marble, and metals. August 2.

12,598. A. L. Blackman. Improvements in or relating to oil presses. August 9.

12,992. G. L. Alemand. A new compound wax. August 17.

13,023. J. L. Moret. A new solid product, applicable for removing grease, washing, lixiviating, and bleaching all textile materials, cloths, rags, and similar materials, for the fulling of cloths, for removing hair from skins, and similar operations. August 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,124. J. C. A. Brunner. Purification of glycerin. August 21.

1889.

9382. E. Cuvclier. Crushing and extracting oil or liquids from oleaginous seeds, &c., and apparatus therefor. July 24.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

11,405. F. L. Bartlett. Improvements relating to the treatment of lead and other fumes in the manufacture of pigments, and to apparatus therefor. Complete Specification. July 16.

11,771. S. Banner. Improvements in or relating to paints or enamels. July 24.

12,034. H. Bedford. Improvements in the manufacture of sealing wax. July 29.

12,292. R. Condy. A new compound to be used in paint or pigment. August 2.

12,492. E. A. W. Dahl. A marine paint or anti-fouling composition. August 6.

12,756. R. Dick. Improvements in gutta-percha compounds, and in the modes and means of preparing and treating the same. August 13.

12,844. T. H. Wright. A new or improved composition for waterproofing and preventing the squeaking of boot soles. August 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,721. W. C. Nangle. Composition or paint for preserving metal, wood, &c. July 31.

1889.

10,858. E. S. Baldwin.—From J. Smith. New composition for waterproofing textile fabrics, and as a paint for wood, &c. August 14.

11,405. F. L. Bartlett. See Application above. August 21.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

11,411. H. E. Freudenberg. An improved machine for treating hides and skins. July 16.

11,549. F. N. B. Rosslyn, R. Rice, and A. T. Haines. A process for extracting grease and animal matters from tanned skins, hides, leather, wool, fur, &c. July 19.

11,797. A. Hommel. Process for the manufacture of soluble blood albumen extracts. July 24.

12,070. A. Weber. Improvements in furnaces or kilns for burning bone-black. Complete Specification. July 30.

12,521. J. Hauff. Improvements in the process for freeing kips, skins, and hides from lime, and for causing the same to swell. August 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,235. W. A. Burrows. Utilisation of leather waste. August 7.

1889.

10,110. J. Hauff. Freeing skins, kips, and hides from lime, and causing them to swell. July 24.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

12,021. A. Chapman.—From C. A. Matthey, West Indies. A process or method of extracting sugar from sugar cane or other sugar-yielding substances and apparatus for the purpose. July 27.

12,393. W. Fairweather.—From The Babcock and Wilcox Co., United States. Improvements in bagasse furnaces. Complete Specification. August 6.

12,809. W. Maxwell. Improvements in multiple effect evaporating apparatus for evaporating or concentrating sugar juice and other liquids. August 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,084. G. Adant. Manufacture of sugar and apparatus therefor. July 24.

13,595. J. G. Lorrain. Treatment of sugar solutions. July 31.

13,655. D. Stewart. Centrifugal apparatus for drying sugar or other granular matters. July 24.

1889.

9994. E. Maigrot and J. Sabates. Apparatus for the manufacture of sugar by electricity. July 24.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

11,339. P. L. F. E. Vignier. An improved mode of and apparatus for distilling whiskies. July 15.

11,623. W. Smith. Improvements in the treatment of malt liquors and spirits. July 20.

11,730. J. White. Improvements in the manufacture of flaked malts. July 23.

12,114. P. G. Wolkoff. An improved process of and apparatus for treating must and other fermented liquid to obtain and purify the alcohol contained therein. July 30.

12,186. P. C. Rousseau, M. J. de Chanterac, and M. J. D. A. de la Baume. A process for purifying alcohol, wine, and other alcoholic liquids and beverages. July 31.

12,187. L. Lederer. Improvements in the manufacture of French yeast and in the machinery employed therein. July 31.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,724. Brin's Oxygen Co., Limited.—From L. Q. Brin and A. Brin. Treatment of spirits, wines, and beer for ageing or maturing them. July 31.

14,328. J. C. Shears and A. Manbré, sen. Apparatus for acetifying alcoholic wash and liquor in the manufacture of vinegar. August 14.

1889.

1582. C. R. Bonne. Preparation of fermentable worts. July 24.

7964. R. Haddan.—From J. C. Severino. Manufacturing a new liqueur. July 24.

8277. J. Leslie. Application of oxygen in the distillation of alcoholic liquids. July 24.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

11,338. W. L. Wise.—From H. von Rom, Germany. Improvements in the treatment and preservation of organic substances, such as flesh or meat and the like. July 15.

11,355. C. H. Roeckner, F. L. Roeckner, and R. L. Roeckner. A new or improved nutritious product. July 15.

11,577. D. Politi. Zucarine jellies in powder. July 19.

11,796. E. Serrant. Process for preserving meat. July 24.

11,806. W. Palmer. The preparation of a solid extract of meat or condensed soup, and a preservative coating for same and other preserved foods. July 25.

12,614. C. W. Beesly and H. S. Holt. An improved compound for preserving milk and other animal matter. August 9.

B.—Sanitary Chemistry.

11,465. C. E. Gittins. Improvements in machinery for water softening and sewage purification. July 17.

11,798. C. G. Moor. Improvements in the treatment of sewage for the purification thereof and the production of valuable products therefrom. July 24.

12,405. H. W. Whiting. Improvements in refuse-burning furnaces. Complete Specification. August 6.

12,623. T. Shaw. See Class IX.

C.—Disinfectants.

11,398. E. Leman. A new preserving powder for meat and fish. July 16.

11,974. F. G. A. Roberts, A. Shearer, and W. B. Giles. An improved manufacture or preparation of antiseptics. July 27.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Sanitary Chemistry.

1888.

11,225. A. B. Lennox, T. Field, and W. Brown. Bread fermentation. August 7.

14,945. E. Edwards.—From J. Lapeyrère. A preparation to be used as a substitute for or in combination with coffee. August 21.

1889.

4893. E. Roberts, L. E. Roberts, and H. G. Roberts. Compound for use in the preparation of table cream, &c. August 7.

B.—Sanitary Chemistry.

1888.

11,663. T. Donnithorne. Treatment of sewage. August 21.

13,761. A. Bobrownicki. Treatment of towns' refuse and other putrescible matters. July 31.

1889.

6528. H. H. Lake. From J. Hirschfeld. Treatment of feculent matter, and apparatus therefor. July 31.

C.—Disinfectants.

1888.

5984. R. Hauman. Sanitary and antiseptic compounds. July 24.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATION.

11,809. W. Proudlock. Improvements in the methods of straining every kind of pulp used for the manufacture of paper. July 25.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

11,150. C. F. Dahl. Blowing out and washing process for making paper pulp from esparto, straw, &c. August 7.

11,458. H. Bache-Wüg, C. Bache-Wüg, and V. B. Drewsen. Producing pure cellulose. July 31.

12,190. C. Weygang. Manufacture of ordinary and waterproof papers, boards, &c. July 31.

13,396. F. Salomon and H. Brüniger. Protecting apparatus used in the manufacture of sulphite cellulose. July 24.

13,741. H. Schulte. Machinery for manufacture of paper. July 31.

15,189. H. J. Allison.—From K. J. Collins. Celluloid and analogous bindings. August 7.

1889.

8903. J. Groome. Machines for pulping materials used in the manufacture of paper. July 24.

9927. H. H. Lake.—From C. T. Lee. See Class IX.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATION.

13,027. A. M. Clark.—From the Firm of F. von Heyden's successor, Saxony. Improvements in the separation of the isomeric substances produced in the manufacture of dithio-salicyleic acid. August 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,892. H. H. Lake.—From C. L. T. Müller. Production of pure ethylic alcohol from crude spirits. August 21.

14,877. G. Christopher and R. W. Leftwich. Preparation and treatment of extract of tea. August 21.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATION.

12,309. J. Williams. Improvements in the treatment of paper or other fabrics, to render them suitable for photographic purposes. August 2.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,301. H. C. Bond. Process for truly reproducing the colours of nature in a compound photographic print. July 24.

16,537. W. Oldham. Method and materials for developing photographic pictures. August 7.

1889.

9921. H. Deveril and W. Gallagher. Photographic negatives and sensitised plates. July 24.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

11,500. P. Ward and E. M. Gregory. Improvements in fuses and detonators. July 18.

11,501. P. Ward and E. M. Gregory. Improvements in the construction of electric fuses and detonators, and in the method of and appliances employed for manufacturing the same. July 18.

11,664. Sir F. A. Abel and J. Dewar. Improvements in the manufacture of explosives. July 22.

11,665. W. Schücker. An improved manufacture of smokeless gunpowder. Complete Specification. July 22.

11,667. Sir F. A. Abel, J. Dewar, and W. Anderson. Process and apparatus for the manufacture of explosives in the form of wires or rods, and for forming the same into cartridges. July 22.

11,711. J. Altschul and R. H. Punshon. Improvements in the manufacture of safety fuse for blasting purposes. July 23.

11,748. J. Harper, R. Punshon, and F. Parker. Improvements in high explosives. July 23.

12,089. P. Giffard. Improvements in mining or blasting cartridges, and in shells or explosive projectiles. July 30.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 9.—VOL. VIII.]

SEPTEMBER 30, 1889.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2 6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

COUNCIL FOR YEAR ENDING JULY, 1890.

President: Sir Lowthian Bell, Bart., F.R.S.

Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schmuck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

A. J. King, B.Sc.	A. Wingham.

NOTICES.

On and after the 30th of September the Editor's address will be "University College, Gower Street, London, W.C.," instead of Owens College, Manchester, as heretofore.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

CHANGES OF ADDRESS.

Communications.

ON CHILIAN MANGANESE ORE.

A Paper read before the British Association (Chemical Section), Newcastle-on-Tyne.

BY JOHN PATTINSON, F.I.C., AND H. S. PATTINSON, PH.D.

PREVIOUS to the adoption of Weldon's manganese recovery process, nearly the whole of the rich manganese ore imported to this country, or mined in Devonshire and Cornwall, was used for generating chlorine in the manufacture of bleaching-powder. About 54,000 tons were used for this purpose in 1868, about the time that Weldon discovered his process. After the general adoption of this process, the demand for manganese ore for generating chlorine was restricted to what was needed to make up the relatively small loss of material incidental to the Weldon recovery process; for this, and for some other chemical purposes, such as the manufacture of manganates, there were used in Great Britain in 1888—20 years later—about 7,000 tons. But the use within recent years of the rich alloys of manganese and iron, known as "ferro-manganese," in steel making, has given rise to a new and large demand for rich manganese ores. The value of ores for this purpose depends upon the proportion of metallic manganese they contain, and not upon their yield of oxygen, as when used for generating chlorine.

Manganese ores are now imported from Spain, Portugal, Hungary, Greece, Canada, New Zealand, and Australia, but by far the greatest quantities come from Canea and from Chili. During the year 1888 about 85,000 tons of manganese ore were imported for making ferro-manganese, of which quantity about 25,000 tons came from Chili. The first shipments of these ores from Chili were in 1883, and so far as we are aware, no analyses of them have as yet been published. The three following analyses of Chilean manganese ores will therefore be of interest. They are made upon samples taken from cargoes of about 1,000 tons

each, and may be regarded as representing the nature of the Chilean ores heretofore imported.

	I.	II.	III.
	Per Cent.	Per Cent.	Per Cent.
Peroxide of manganese.....	69.23	57.06	66.03
Protoxide of manganese.....	11.92	23.05	10.39
Peroxide of iron	1.67	4.71	1.59
Oxide of lead	0.00	0.06	0.05
Oxide of copper.....	0.15	None.	0.14
Oxide of zinc	0.10	None.	None.
Nickel and cobalt.....	None.	None.	None.
Alumina	1.21	2.80	1.60
Baryta.....	None.	None.	3.58
Lime	1.13	2.33	5.36
Magnesia	0.24	0.56	0.13
Potash	2.86	0.46	0.15
Soda.....	0.08	0.26	0.11
Silica	1.17	7.30	4.75
Carbonic acid (CO ₂).....	None.	0.18	2.33
Sulphuric acid (SO ₃).....	0.05 (=0.02 S)	0.13 (=0.05 S)	1.57 (=0.63 S)
Phosphoric acid (P ₂ O ₅)	0.12 (=0.05 P)	0.14 (=0.06 P)	0.05 (=0.02 P)
Arsenic	Not determined.	0.15	0.04
Combined water	3.90	3.00	1.96
	99.92	100.19	99.94
Metallie manganese.....	53.00	52.63	49.79

The analyses were made on the samples dried at 100° C., at which temperature they lost, respectively, 2.47 per cent., 1.08 per cent., 0.98 per cent. of hygroscopic moisture.

No. I. comes from the neighbourhood of Santiago, and was shipped from Valparaiso; Nos. II. and III. are from the vicinity of Coquimbo and Carrizal, which are now the chief ports of shipment. Nos. I. and II. are very hard compact amorphous ores of a bluish-black colour, and often exhibit a conchoidal fracture; No. III., which contains more peroxide than the others, is softer and of rather a darker colour, and crystals of calcium carbonate are frequently found disseminated through it.

The ore is found in stratified beds varying in thickness from a few inches to six feet. These beds occur in the range of hills along the coast of Chili, known as the "Cordilleras de la Costa," and are found out-cropping in the sides of the hills, at varying distances one below the other, often to the number of four or five. These beds are much distorted and are interrupted by frequent faults.

A characteristic of Chilean manganese ores is the large percentage of protoxide of manganese they contain—a much larger percentage than is found in Caucasian or Spanish ores, which usually contain no more than from one to two per cent. of protoxide.

It is well known that manganese dioxide acts the part of a feeble acid, and, when precipitated, carries down with it as manganites, protoxide of manganese, baryta, lime, potash, and other bases with which it was in solution. It is probable, therefore, that in these ores the protoxide of manganese has been deposited in combination with the peroxide in the form of manganite of manganese. In No. I. there is an unusual amount of potash, and in No. III. the percentage of lime and baryta is high. A part of the baryta exists as sulphate, and a part of the lime as carbonate, but no doubt portions of these bases as well as the potash have been precipitated with the manganese

dioxide, and exist in these ores as manganites. Baryta is no uncommon constituent of manganese ores. In some Caucasian ore as much as 2.04 per cent. has been found. Potash, also, is found in other ores than Chilean, and we have met with one specimen which contained as much as 1.15 per cent. The silica in the Chilean manganese ores is sometimes in the form of quartz, but it also exists very frequently as a silicate of manganese. It is also to be observed that these Chilean ores contain a very low percentage of phosphorus, a matter of great importance to the steel maker. The amount of phosphorus varies to a slight extent, samples of some cargoes having had about 0.10 per cent. of this constituent. No. II. contains a small quantity of arsenic, which has been shown by Pattinson and Stead (Journal of the Iron and Steel Institute, 1888, Part I.) not to be so deleterious an ingredient of steel as phosphorus.

Enormous beds of manganese ore, containing between 30 and 40 per cent. of manganese and a large percentage of calcium carbonate, have been discovered in Chili. These deposits are practically inexhaustible, but as yet only the richer ores, containing about 50 per cent. of manganese and upwards, can be profitably exported. Perhaps in the future, should the means of transport become cheaper, these poorer ores may be brought into the market.

THE PRODUCTION OF THE ALLOYS OF ALUMINIUM AND SILICON IN THE ELECTRIC FURNACE (COWLES' PROCESS).

*Read before "B" section, British Association,
September 13, 1889.*

BY J. H. J. DAGGER, F.C.S., F.A.C.

Historical.—Although aluminium is one of the most widely distributed of the elements entering into the composition of nearly two hundred minerals, its oxide alumina was regarded as identical with lime until, in 1754, Margraff proved it to be a distinct substance.

In 1807, Davy, so successful with the oxides of the metals of the alkalis and alkaline earths, attempted to decompose alumina by the battery, but failed; and it was not until the year 1828 that Wöhler, by heating the chloride with metallic potassium, first obtained aluminium as a grey lustrous metallic powder, and 18 years later in globules not larger than pin heads; from these with extreme ingenuity he determined the principal properties of the metal. In 1854, Deville (at that time Professor of Chemistry in the École Normale, Paris), in course of some researches on the chloride, obtained a button of pure aluminium by the decomposition of the chloride with sodium, and on the 14th February that year read a paper describing his discovery before the Academy of Science. As a result a committee was formed to carry on experiments, 2,000 francs being granted to meet expenses. On August 14th he read a second paper before the Academy, exhibiting several bars of aluminium, and caused a medal of the metal to be struck and presented to the Emperor.

In March of the next year experiments on a large scale at the Imperial cost were instituted at Javel, and on June 18th, Deville presented to the Academy, through M. Dumas, large bars of pure aluminium. These experiments are said to have cost the Emperor 35,000 francs (1,158*l.*).

Devil's method, modified in details, is still the chief of the chemical methods of preparing aluminium on a commercial scale, and is dependent on the cost of the metallic sodium and the double chloride of aluminium and sodium, which is the compound used in the most important of the present day processes.

Pure aluminium is a highly lustrous metal, white with a faint tinge of blue in colour. It resists the action of air and moisture even at high temperatures, is not blackened by

exposure to the action of sulphuretted hydrogen or the alkaline sulphides, and is not attacked by fused nitre, nitric or dilute sulphuric acid. It dissolves readily in hydrochloric acid or in solutions of the alkalis.

Its density is but two and one half times that of water, compared with other metals its density is as follows:—

Metal.	Density.	Compared with Aluminium.
Platinum	21.5	8.6
Gold	19.3	7.7
Lead	11.4	4.8
Silver	10.5	4.2
Copper	8.9	3.6
Iron	7.8	2.9
Tin	7.3	2.8
Zinc	7.1	2.8
Aluminium	2.5*	1.0

* Cast metal 2.56. Rolled or hammered metal 2.67.

In a paper read by Mr. W. H. Barlow before the British Association, 1882, its tenacity is given at 12 tons to the square inch, but weight for weight it would equal high class steel or 36 tons per square inch. Its elasticity is almost equal to that of silver. Is ductile, can be drawn into very fine wire, and is almost as malleable as gold. Its thermal conductivity is about two-thirds that of copper. Its electrical conductivity is given by Deville as eight times that of iron. Its specific heat is .22, it melts at 1300° F.,† but exhibits no tendency to volatilise even though heated in a carbon crucible in a blast furnace to high temperatures.

The extreme lightness of aluminium, its power of resisting the action of air, moisture, and sulphuretted hydrogen give it an advantage over silver which it equals in tenacity and elasticity as a material for jewellery, and for scientific and astronomical instruments.

The greatest value of aluminium is as yet in its alloys, and it is with their production in the electric furnace I propose to deal to-day, and I may remark that the successful application of the intense heat of the electric arc to the production of metals on a commercial scale, marks a new departure in electro-metallurgy of which we cannot over-estimate the importance, rendering it possible to produce rich alloys of aluminium at half the cost of any other process, and so widening the field of their application to an extent hitherto unknown.

TRANSVERSE AND LONGITUDINAL SECTION OF THE COWLES ELECTRICAL FURNACE.

Messrs. Cowles' first experiment was with a very refractory zinc ore containing silver, which they had failed to reduce in an ordinary furnace. A fireclay tube was taken filled with a mixture of the crushed ore and charcoal powder, a bundle of electric light carbons inserted in each end, and a current from a small dynamo sent through the mass; in a short time the ore was reduced, but the fireclay tube was partly melted, showing the necessity for a lining that would protect the furnace walls from the intense heat. Powdered charcoal, a very feeble conductor of heat and electricity, was tried, but it was found that after a time it became

converted into graphite, thus becoming a conductor, as the smelting proceeded changing gradually from the inside to the outside, and as the hot zone expanded causing loss of energy and eventually destroying the furnace. Mr. Alfred H. Cowles then suggested soaking the charcoal powder in milk of lime, and drying before use. This proved successful, each particle of charcoal being coated with a film of lime, which insulates it and prevents electrical conduction between neighbouring particles even after the charcoal is

† Bailey gives 700° C. = 1,484° F.

converted into graphite. Messrs. Cowles now found that they had a furnace that would enable them to conduct metallurgical operations at a temperature hitherto unknown outside the laboratory, and after some experiments with corundum, they, acting in conjunction with Professor Mabery, set up the first plant for the production of aluminium bronze, ferro-aluminium and silicon bronze at the works of the Brush Electric Company, Cleveland, Ohio, U.S.A., and on the 20th January 1886 Mr. E. H. Cowles read a paper before the Franklin Institute describing the electric furnace and a process of making aluminium bronze. The Institute thought so highly of the importance of the discovery that they awarded to Messrs. Cowles the "Elliott" gold medal, the highest honour in the gift of the Institute. The City of Philadelphia awarded them the "John Scott Legacy" medal, this being the only instance of the two awards falling to the same inventors.

In 1887 Mr. E. H. Cowles was elected a Fellow of the Royal Society.

The results obtained at Cleveland were so satisfactory though using only a dynamo of 300 ampères with E.M.F. of 60 volts, that in 1886 the Cowles Company commenced the works at Lockport, N.Y., U.S.A. The works at Lockport commenced operations with a Brush dynamo giving a current of 1,500 ampères with an E.M.F. of 45–60 volts; to this has been added two dynamos, each capable of supplying a current of 3,000 to 3,200 ampères with an E.M.F. of 55 to 60 volts. A fourth dynamo is now building of 3,000 ampères.

One striking feature of the Lockport works is the use of water-power, the dynamos being actuated by two powerful turbines, 30 inch diameter = 500 horse-power.

The number of furnaces in operation are 14, producing about 300 lb. of aluminium contained in alloys per 24 hours. Four additional furnaces are now building.

I will now describe the English works of the company at Milton, Staffordshire.

The Milton Works.—These, the first electro-metallurgical works established in Europe, are situated near Milton station, on the North Staffordshire railway, with which system they are connected by a siding, and also abut on a branch of the Trent and Mersey canal, thus affording facilities for cheap transit of raw material, coal, and finished products.

The experience at the Lockport works showed conclusively that great economies were to be expected from increasing the size of the furnaces, and the strength of the electric currents, but no current of more than 3,000 ampères had been used up to the time the Milton works were planned.

Mr. Cowles then prepared a specification for a dynamo to give a current of 5,000 ampères at 60 volts, and eventually Messrs. Crompton's designs were accepted.

Dynamo.—This dynamo is of 500 h.p., and furnishes a current of 5,000 to 6,000 ampères, with an E.M.F. of 50–60 volts. It is said to be the largest machine (at least in regard to quantity of current) in England, and probably in the world. I will not describe this magnificent machine more fully, as it was the subject of a very interesting paper read by Mr. Crompton before the "G" section of the Association last year.

Boilers.—The boilers supplying steam to the works are of the Babcock-Wilcox type, representing 600 h.p., and are fitted with mechanical stokers; by this means one man can easily attend to the generation of steam for the whole works.

Engine.—The main engine used for driving the dynamo only is a compound condensing horizontal tandem engine, made by Messrs. Pollitt and Wiggell, of Sowerby Bridge, and is well worthy noting for its beautiful workmanship. Its motion is indeed so silent that with your back to it at the moment of starting you cannot tell whether it is in motion or not. It is of 600 h.p., and is provided with automatic expansion gear, and the centrifugal governor maintains the speed at 76 revolutions. It is needless to say that work of this kind involves rapid fluctuations of load, and as an additional precaution against racing, the engine is fitted with Tate's electrical "stop-valve," which stops the engine automatically if the speed exceeds a certain limit. It

can also be stopped from various points in the engine and furnace rooms by means of push-buttons connected in parallel with the main circuit leading to the Tate's valve.

The engine has a 23-in. high-pressure and a 43-in. low-pressure cylinder. The stroke is 5 ft., the average steam pressure being 85 lb. The flywheel is 20 ft. in diameter, and weighs 20 tons; it is geared to the dynamo by 18 driving ropes, so that the dynamo makes five revolutions for each revolution of the engine.

The Current.—From the dynamo the current is led by copper bars to an enormous "cut out," calculated to fuse at 8,000 ampères. This is probably the largest ever designed, and consists of a framework carrying 12 lead plates, each $3\frac{1}{2}$ in. by $\frac{1}{16}$ in. thick. From this it passes into the furnace rooms. A current indicator is inserted in the circuit, consisting of a solenoid of nine turns. (This was cut out of a cylinder of cast copper by means of a parting tool in a screw-cutting lathe.) In the solenoid is an iron core suspended by a spring. The movement of this is communicated to two pointers, one dial being placed in the engine room, the other in the furnace room. The range of the indicator is such that the entire circle of $360^\circ = 8,000$ ampères.

Furnaces.—There are two furnace rooms, each containing six furnaces. The first room contains the bronze furnaces, in which is carried on the manufacture of aluminium copper and silicon copper. The second is devoted to the production of ferro-aluminium. The furnaces are rectangular in form, built of fire-brick, the internal dimensions being 60 in. by 20 in. by 36 in. Into each end is built a cast-iron tube, through which the carbon electrodes enter the furnace.

Electrodes.—Each electrode consists of a bundle of nine carbons, each $2\frac{1}{4}$ in. diameter, attached to a head of cast iron for ferro-aluminium, or cast copper when cupro-aluminium is made. Each carbon rod weighs 20 lb. Quite recently it has been possible to obtain carbons 3 in. diameter weighing 36 lb.; these are employed in bundles of five. The "head" of the electrode is screwed to the copper rods or "leads," which can be readily connected with or disconnected from the flexible cables supplying the current.

Each cable is secured to slides running on omnibus bars of copper overhead, so that it can be brought into position opposite the furnace to be used.

The electrodes are arranged so that it is possible, by means of a handle and screw, to advance or withdraw them from each other in the furnace.

Lining.—Lining the furnace is the first operation preparatory to smelting; this is done by covering the bottom of the trough with a layer of prepared charcoal.

Charcoal Lining.—Oak charcoal is used. This is ground under edge runners, treated with milk of lime and dried, first in a steam-jacketed revolving drum, and afterwards on a hot iron plate. Each particle of charcoal is thus coated with an insulating film of lime.

The electrodes are now arranged in the furnace, and a "former," consisting of two pieces of sheet iron connected by stirrups arched so as to fit over the electrodes, forming a box without top or bottom (the size being dependent on the charge used), is dropped over the electrodes. Prepared charcoal is then rammed into the space between the iron sheet and the fire-brick walls of the furnace. This done, the charge of ore mixed with coarse charcoal and the metal to be alloyed with the aluminium, in form of turnings or granules, is placed inside the iron box, after which this is carefully withdrawn. Some broken pieces of carbon are arranged so as to connect the electrodes and start the current. The charge is then covered with coarse charcoal, and the cast-iron cover, having a hole in the centre for the escape of gases, is lifted into place and luted so as to prevent the entrance of air.

The commencing current is about 3,000 ampères, gradually increasing to 5,000 ampères in the first half-hour. The time occupied by a "run" is about $1\frac{1}{2}$ hours. Soon after starting the gases escaping from the orifice in the cover take fire and burn with a white flame. This gas consists mainly of carbonic oxide, with small quantities of the hydrocarbons and nitrogen. On the conclusion of the run the furnace is allowed to cool, the melted alloy collecting in the bottom of

the furnace. The next furnace, ready charged, is connected, so that the process is a continuous one, the furnaces being successively charged and connected.

A form of furnace in which the metal is tapped from the bottom has given very satisfactory results.

The energy required to produce 1 lb. of contained aluminium depends of course upon the grade of alloy, the average being 18 h.p. per hour.

The crude metal from the furnace is then refined and remelted in a reverberatory furnace, each "run" is sampled, and the percentage of aluminium ascertained by analysis.

The nature of the reaction that takes place in the electric furnace is not very easy to ascertain. The reduction of the ore takes place in an air-tight box, and in presence of an enormous excess of carbon. It may be assumed that at the intense heat of the electric arc the ore melts and give up its oxygen to the carbon—

The presence of copper or iron is immaterial, as the reaction takes place with ore alone, but in absence of the alloying metal the liberated aluminium absorbs carbon and is converted into a carbide.

Professor Hampe, however, contends that the reaction is in two stages, the first being electrothermic, in which the ore melts; the second electrolytic, in which electrolysis of the molten oxide takes place, aluminium being liberated. Supposing an alternating current is used in the furnace instead of the continuous, and that we have a high number of alternations—from recent experiments with alternating currents we know that very slight or no electrolytic action occurs—if then we get equal results, it would go to prove that the action is thermic, and *not* electrolytic.

Alternate Current Experiment.—An experiment was made by the Cowles Company using an alternating current.

The furnace used was 48 in. by 12 in. by 24 in. with current of 900 ampères with E.M.F. of 50 volts, alternations per minute 11,000. At the end of 1½ hours we obtained 45 lb. of 4 per cent. aluminium bronze.

This investigation was purely of an experimental character, and it cannot be doubted that on the larger commercial scale the result would be more satisfactory.

The results obtained were identical with those given by the continuous current in every way, the resultant slags similar in composition.

The slag from the electric furnace is really only melted unrefined ore and not a slag in the proper sense of the word. Its approximate composition is Al_2O_3 90, SiO_2 2.00, Fe_2O_3 4.00, CaO 3.9, P 0.10.

The charcoal from the old linings which has been partially converted into graphite is re-crushed and treated with milk of lime, dried as before, and thus used many times over. The crude metal from the "runs" is remelted with a fluor-spar as a flux and tapped from the reverberatory furnace into ingots or plates, the refinery slag is put into a revolving drum for breaking into pieces, and then washed to remove carbon; the entangled particles of alloy are thus recovered and are worked up with other charges.

These operations are carried out in a separate building, the reclaiming house.

Production.—These works produce about 260 lb. of contained aluminium per 24 hours, the most valuable alloy being aluminium bronze, which is supplied in grades* containing 1½ to 11 per cent. aluminium. To obtain these the rich furnace product containing 15 to 20 per cent. aluminium is remelted and reduced to the desired percentage with metallic copper and cast in 12 lb. ingots.

I have now described the most important features of the electro-metallurgical industry as carried on at Milton, and will proceed to describe the chief properties of the alloys produced and some results obtained from them.

The Alloys of Aluminium.—With copper, aluminium forms a series of interesting and beautiful alloys varying in colour from bluish-white to red gold and pale yellow, and also differing widely in physical and mechanical properties.

Alloys containing 60 to 70 per cent. aluminium are very brittle, glass hard and beautifully crystalline. With 50 per cent. the alloy is quite soft, but under 30 per cent. the hardness returns. The 20 per cent. bronze has a whitish-yellow tint and somewhat resembles bismuth, it is very brittle and can be pulverised in a mortar.

The brittleness of alloys containing more than 11 per cent. prevents their use, but from 11 per cent. to 1½ they are of very great value, possessing great tensile strength, high resistance to compression, low specific gravity and greater resistance to corrosion than any alloy known.

The following gives the density of these alloys compared with other metals and alloys:—

Metal.	Density.
Aluminium bronze, 3 per cent.	8.69
" " 4 "	8.62
" " 5 "	8.37
" " 7.5 "	8.00
" " 10 "	7.69
" " 11 "	7.23
Brass.....	8.38
Cannon bronze	8.23
Cast bronze	7.20
Cast steel.....	7.71
Iron.....	7.80
Nickel.....	8.57
Silicon.....	2.67
Platinum.....	21.50
Gold.....	19.30
Lead	11.40
Silver.....	19.50
Copper	8.90
Tin.....	7.50
Zinc.....	7.10

Cu₉Al.—The standard "A" grade, containing 10 per cent. aluminium, behaves as a true alloy, that is will not liquefy out into different combinations. It resembles pale gold in colour. Its tensile strength in castings run from 75,000 lb. to 90,000 lb. to the square inch with from 4 to 14 per cent. elongation.

The following is the report of a test of 10 per cent. bronze produced by the Cowles process, made by Professor Unwin and alluded to in his work on the "Testing of Materials of Construction," p. 348.

The bar was 0.499 in diameter and was placed in shackles which have spherical bearing surfaces, so that the tension was extremely uniform on the section.

Breaking weight, 7.195 tons = 36.78 tons per square inch, 89,743 lb.

Elongation in 10 inches, 3.326 inches = 33.26 per cent.

Contraction of area, 0.078 inches = 39.87 per cent.

Elastic limit, 3.47 tons = 17.74 tons per square inch.

The elongation in different parts of the bar was much more uniform than with iron or steel.

One-inch lengths measured after fracture—

1.	2.	3.	4.	5.	6.
1.27	1.27	1.26	1.28	1.27	1.26
7.	8.	9.	10.	11.	12.
1.28	1.20	1.34	1.36	1.44	1.44

* "High grade" furnace, product 20–30 per cent. Al.

The high elastic limit in a material so plastic is noteworthy.

In *resistance to compression** this metal equals the best cast steel; its *transverse strength* or rigidity is about 40 times greater than ordinary brass; its limit of elasticity equals steel of the same tensile strength and elongation; forged, tempered, and annealed, its elongation equals the best grades of steel of the same strength.

The "Special" grade contains more aluminium than "A" grade; is higher in tensile, transverse, torsional strength and elastic limit, its elongation is less varying from nil to 8 per cent.

The following was a test made at Washington Navy Yard of metal of this grade supplied by the Cowles Company's works.

	Diameter.	Area.	Total.	Per Sq. In.
1 Round bar casting	.285	.0643	3.7	57.27 (128,400 lb.)

For the Leeds Forge Company,
(Signed) SAMRSON, FOX, MAY, & Co.

All grades of this bronze under 11 per cent. can be rolled, swaged, or drawn cold, and is the only bronze that is not "hot short," and can be worked at a bright red heat as easily as wrought iron. Under the hammer it can be drawn out to the fineness of a needle.

The rolling of sheets, rods, bars, and wire is done at bright heat, only the finishing being done cold. Rolling or working this metal in any way makes it stronger and tougher. A "rolled" rod "B," grade, tested at the Otis Iron and Steel Works, Cleveland, Ohio, showed tensile strength 83,000 lb. (37 tons) to the square inch with 39 per cent. elongation before breaking. In the casting this metal had but 60—65,000 lb. (26.7—29 tons) tensile strength, with 20 per cent. elongation.

The fracture of the special and "A" grades exhibit a crystalline structure; the lower grades are extremely fibrous.

The beautiful colour and power of resisting corrosive influences make aluminium bronze valuable in art metal work.

In the church of St. Germain, Paris, are 12 beautiful candlesticks, 6 ft. high, and a crucifix, 4 to 5 ft. in height, made of 5 per cent. aluminium bronze; these have been in position over 20 years, and their colour is still perfect. In Philadelphia, the statue of Wm. Penn, intended to surmount the dome of the new city hall, will be cast in aluminium bronze.

Aluminium brass is another valuable alloy made by combining aluminium bronze with zinc in different proportions. It is a close-grained, homogeneous, and tough metal.

The torpedo shell before you is cast from this metal (the No. 2 grade).

Aluminium Brass.	Tensile Strength in Castings per Sq. In.	Elongation.
No. 1	Tons. 23—27	Per Cent. 10—14
No. 2	30—34	6—11

This alloy forges hot, and its special casting properties, its resistance to corrosion, its low specific gravity, render it valuable as a material for ships' propellers, stern and rudder frames, pump plungers and rods, valves, wheels, and pinions, and for hydraulic and engineering work generally.

A number of tests were made by order of the Navy Department of the United States of aluminium bronze and brass as compared with United States gun bronze, with favourable results. A blade could be made of it at least one-third thinner than cast iron or any other bronze blade, and would be that much lighter (*see table of tests*).

For cartridge shells this alloy cannot be equalled: their strength would enable a thinner and lighter shell to be used

The B, C, D, and E grades, containing $7\frac{1}{2}$, 5, $2\frac{1}{2}$, and $1\frac{1}{4}$ per cent. aluminium respectively, decrease in tensile strength from about 65,000 per square inch in B, to 25,000 lb. in E grade. The transverse and torsional strength, elastic limit and resistance to compression decreasing as the aluminium is lowered, elongation increasing in the same proportion. The E grade metal will stretch nearly two-thirds of its length before rupture, which exceeds that of pure copper by about 100 per cent. A piece of C grade wire can be twisted through several hundred turns before breaking. A rolled bar of C grade (5 per cent.) tested at the Phoenix works, Rohort, Germany, gave—

Tensile strength 82,880 lb. to square inch, 37 tons.

* Compression test 156,000 Watertown Arsenal test.

with the advantage of not being corroded by the contained explosive. The use of aluminium bronze as a material for cannon was the subject of a paper read before the United States Naval Institute. As early as 1859 a mountain gun of this metal was cast and tested by the Committee of

Artillery of France with very favourable results—the high price of aluminium being then the only thing prohibitive of its widespread use for guns.

The following are some of the results of mechanical tests of aluminium bronze and brass:—

COMPRESSION TESTS MADE AT WATERTOWN ARSENAL, U.S.A.

Original Length.	Shortened to Inches.	Original Diameter.	Increased to Inches.	Ultimate Strength.	Ultimate Strength per Square Inch.	Specimen (Casting).
Inches. 2'00	Inches. 1'705	Inches. .798	Inches. .865	80,200	Lb. 160,400	"A" 1 Bronze.

Ferro-Aluminium.—The alloys of aluminium and iron have long been known. They are referred to by Faraday, who found 0.013 to 0.69 per cent. aluminium in "Wootz" steel. Rogers, in an article in the "Moniteur Industriel," No. 2379, 1859, says a small per cent. of aluminium makes steel hard, strong and brittle, a larger quantity makes it very dense, without impairing its peculiar polish or detracting from its qualities.

The influence of aluminium in small quantity on cast iron is very marked, and was last year the subject of an interesting paper by Mr. W. J. Keep, in conjunction with Professor Mabery and L. D. Vorce, of the Case school of applied science, Cleveland, Ohio, U.S.A., read before the American Association for the Advancement of Science, August 1888.

Two bases were used—one a white iron, with composition Si 0.186, P 0.263, S 0.0307, Mn 0.092. The other, grey

Swedish iron, marked F.L.M., with Si 1.249, P 0.084, S 0.004, Mn 0.187. The ferro-aluminium used was made by the Cowles process, and contained Si 3.86, Al 11.42 per cent. Each base was experimented upon separately, and at the same time a series of blank trials were made, the metals in the two series being subjected to exactly the same conditions.

The following results were obtained:—

1st. Solidity of castings and prevention of blowholes. The aluminium castings were of a slightly finer grain and of increased solidity. With 0.1 per cent. Al present the resistance to dead weight was increased about 44 per cent. and to impact 6 per cent.

2nd. Does the aluminium remain in the iron after re-melting? The white base, after the addition of 0.25 per cent. of aluminium, was re-melted six times, fresh quantities of the white base being added each time. That the aluminium remains in and improves the iron is shown by the superior and stronger castings obtained in this series, even after the percentage of Al had become very low, than in those cases where no aluminium was added.

3rd. The effect of aluminium on the grain. Aluminium seems to enable iron to hold in solution all its carbon until just upon the point of solidification, when it is precipitated in a finely graphite form. The advantage of this is the uniformity of the mass and the absence of pockets of graphite, which are generally produced when ordinary grey iron has been cooled slowly. Hence the homogeneity and greater strength of the aluminium castings. The rapidity of cooling makes little or no difference, as the release of the carbon seems to be instantaneous and only at the moment of crystallisation.

A very little aluminium is sufficient to precipitate graphite from white iron, 0.25 per cent. rendering it perceptibly darker in colour, 0.5 per cent. more so, whilst 0.75 per cent. renders it quite grey with no signs of white. With increasing amounts up to 4 per cent., the maximum in all these experiments, the effect is the same, the castings becoming softer and greyer as the amount of aluminium increases. The presence of much silicon does not alter the matter, the grain being the same also in thin and rapidly cooled, as in thick castings.

4th. Aluminium castings are not affected by chilling. Graphite is liberated whether the casting is cooled rapidly or slowly, with the result that the grain is uniform and there is no chill.

5th. When sufficient aluminium is present to liberate the graphite, a coating is formed on the casting which resists the sand and the heat, and prevents the iron burning the sand into itself.

6th. The fineness of the grain causes them to be more easily cut than cast iron of coarser grain.

7th. The presence of aluminium increases the strength to sustain a constant load, but the strength does not increase uniformly with the percentage of aluminium.

8th. The increase in strength is much greater and more marked than in the preceding. Above a certain percentage the strength diminishes, due to larger amount of graphite liberated.

9th. Elasticity is improved.

10th. The fineness and compactness of iron containing aluminium gives less permanent set than iron equally as soft when that softness is produced by silicon.

11th. The shrinkage is slightly increased with a small quantity of aluminium, due probably to the elimination of blowholes, but with 0.75 per cent. and more it is much decreased, especially in case of the wrought iron.

12th. In case of the white iron fluidity is much increased. With grey base containing much silicon it is not so clear, though it is believed the fluidity is increased.

The fact that aluminium lowers the melting point of iron is utilised in the Mitis castings, the invention of Mr. Peter Ostberg, of Stockholm. In making Mitis castings, a very small quantity of aluminium, about 0.50 per cent. Al, in form of 7 or 8 per cent. ferro-aluminium is added to the charge (about 60 lb.) of wrought iron in the crucible the moment this has been melted. The fusing point is at once lowered about 500°, and the charge becomes very fluid and can be cast in the finest moulds, while the great difference between its temperature and its fusing point gives all the time necessary for its manufacture without danger of its solidifying.

The tensile strength of Mitis castings may be as high as 27 tons per square inch, with an elongation of 20 per cent. Another alloy made in the electric furnace is silicon bronze, which, owing to its great strength and tenacity, its resistance to corrosion, combined with high electrical conductivity, is perhaps the best metal extant for electric light, telephone, and telegraph wires.

In conclusion, may I direct your attention to the test bars, castings, and specimens of aluminium alloys made by the Cowles process, kindly lent for this paper by the Cowles Syndicate Company, Limited.

Specimens of Aluminium Alloys made in Cowles' Process. Exhibited in connexion with Paper read before "B" Section, British Association.

No. 1. Aluminium bronze cylinder (torpedo shell).—2 feet long, 14 inches diameter; cast in sand with core, outside finely polished; inside rough. Test bars taken from same pouring gave: Tensile strength, 105,000 lb. per square inch (46.87 tons); elongation, 6 per cent.

No. 2. Cylinder same as above, made from aluminium brass "No. 2" (one-third zinc) (33.3 per cent.).—Tensile strength, 90,000 lb. per square inch (40.17 tons); elastic limit, 66,000 lb. per square inch (29.46 tons); elongation, 6 per cent.

No. 3. Piece of calico-printing cylinder, 6 inch diameter and about 1 foot long. Cast by Messrs. Bolton and Sons, Oakamoor Mills, Cheadle, Staffordshire, in the same manner as they cast their copper cylinders.

No. 4. Dynamo hub of aluminium brass "No. 2."—This metal has a tensile strength of 93,000 lb. to the square inch, and 5 per cent. elongation. The German silver that has heretofore been used in the Brush hubs has but 44,000 lb. tensile strength, and 24 per cent. elongation, and costs much more than this brass.

No. 5. Billet of 10 per cent. aluminium bronze cast in chill.—One entire side polished to show perfect casting, colour, &c.

No. 6. Lathe turnings of aluminium bronze, showing no signs of oxidation after three years' exposure to the atmosphere.

No. 7. Aluminium "pig" casting (80 per cent. aluminium).—Produced directly by heat of electric furnace reduction of oxide of aluminium by carbon. (Believed to be the first reduction by carbon of this oxide.)

No. 8. North Metropolitan (London) Tramways Company's "car bearing" of ordinary gun-metal after a year's wear, and originally of same dimensions as No. 9.

No. 9. Same company's car bearing made from Cowles' aluminium bearing metal after a year's running on same route as No. 8, no wear being perceptible.

No. 10. Aluminium bronze bar, one end hammered hot, other end twisted cold.

No. 11. Five per cent. aluminium bronze bar.—Bending test, bent cold.

No. 12. Ten per cent. aluminium bronze rolled sheet.—Test, spring by bending.

No. 13. Five per cent. aluminium bronze rolled bar. Tested at Phoenix Works, Ruhort, Germany.—Tensile strength, 82,880 lb. to square inch (37 tons); elongation, 60 per cent.

No. 14. Five per cent. aluminium bronze cup drawn cold from a 9-inch disc.

No. 15. Sample of silicon copper product run direct from furnace. Silicon = 15.08 per cent.

No. 16. Bar of basic Siemens steel, tested at Phoenix Works, Ruhort, Germany, showing bending and fracture.

No. 17. Bar of 10 per cent. Cowles' aluminium bronze, tested at Phoenix Works, Ruhort, Germany, showing bending and fracture.

No. 18. One-inch round bar of aluminium bronze.

No. 19. Two-inch square bar of aluminium.

No. 20. Propeller blade of No. 2 aluminium brass.

No. 21. Ores, slags, and fragments of carbons from the electric furnace.

No. 22. Drawings and views of the furnace, engine, and dynamo.

No. 23. Photographs of the "Cowles'" aluminium works, Milton, Staffordshire.

A NOTE ON THE VOLATILISATION OF LEAD OXIDE, AND ITS ACTION UPON GLASS AT LOW TEMPERATURES.

A Paper read before the British Association, Newcastle-on-Tyne, September 1889.

BY T. W. HOGG.

LEAD oxide in a state of fusion attacks silica with great readiness, and by merely exposing a mixture of these substances to a red heat for some time combination will take place without the mixture having been in a state of fusion; it is therefore not surprising to find that glass should be acted upon by lead oxide at a comparatively speaking low temperature.

If a polished plate of glass be coated with oxide of lead and then heated up to a temperature of scarcely visible redness, or even slightly below this, it will be found, after cooling and removing the surplus oxide, that the surface has

been distinctly corroded, owing to the oxide having entered into combination with the constituents of the glass. The corroded parts produced by conducting the operation at this temperature possess quite a smooth surface, but if the corrosion be allowed to take place at a decided red heat the parts are rough and not unlike the effect produced by dry hydrofluoric acid. By soaking these corroded plates in a solution of ammonium sulphide the lead may be converted into sulphide of lead, and the corrosion may be so varied under different conditions that brilliant mirror-like films may be obtained of considerable durability and of sufficient thickness to be quite opaque, or so thin that light of a brownish hue is transmitted.

Upon examining these corroded parts under the microscope the limit of each mark was observed to possess a delicate fringe easily seen by very oblique light, and especially if the glass was observed from the reverse side, the appearance being similar to what might be produced by a slightly volatile substance. Whilst submitting this point to a more careful examination it was found that if a plate of glass was written upon, using lead oxide as a pigment, and another plate, preferably of some dark blue or ruby tinted glass, placed immediately over it but prevented from actual contact by suitable means—if these were then heated for about one hour to a temperature of scarcely visible redness, the upper glass always had its polish so altered that a distinct reverse of the writing appeared upon it, more or less sharp according to the distance between the two surfaces.

It was suspected at first that this result was produced by the mechanical transportation of particles of the oxide, as the expulsion of moisture from moist substances is often accompanied by the expulsion of part of the substance itself. This suspicion, however, was easily disposed of by previously heating the oxide before placing the upper glass over it; the effects were just as easily obtained with this precaution, and quite a conclusive experiment consists in

actually fusing the oxide upon a platinum support; if this is then covered by a plate of glass and prevented from actual contact in the usual way, and heated to the usual temperature, the polish of the glass will also be distinctly altered. The effects are also obtained if a little lead oxide be placed in a platinum crucible and this covered by a piece of dark blue glass; in this case it requires exposure to the low temperature for two or three hours before the glass is tarnished. It is generally understood that lead oxide is not sensibly volatile below its fusing point, and so far as the indications of the balance are concerned this may be quite true; it is therefore very interesting to know that by the experiments here described, it can be shown that lead oxide volatilises at a scarcely visible red heat in such quantities that fail to be recognised by the most sensitive balance.

ON SOME RESULTS OF ANALYSES OF OLIVE OIL FROM DIFFERENT SOURCES.

BY LEONARD ARCHBUTT.

THE examination at various times during the past seven or eight years of samples taken from large bulks of olive oil intended for lubricating has afforded an opportunity of making a comparison of the oil from several different sources; but as, unfortunately, only a fraction of the samples have been labelled with the port of shipment, the number available for purposes of comparison is not so large as it might have been.

The results are arranged in the following table, and the following conclusions may be drawn from them:—

Source of the Oils.	Total Number of Samples.	Number Examined for Adulteration as well as for Acidity.	Number found Genuine.	Per Cent. found Genuine.	Free Fatty Acid (= Oleic Acid).		
					Highest.	Lowest.	Average.
Seville.....	32	32	31	96·8	10·0	1·5	4·4
Malaga.....	35	35	27	77·1	25·1	2·0	6·7
Unknown.....	3	3	2	66·6	5·6	2·1	3·3
Spain (total).....	70	70	60	85·7	25·1	1·5	5·5
Gallipoli.....	19	18	17	94·4	16·9	·9	7·3
Gioja.....	12	8	8	100·0	25·2	4·1	10·9
Monopoli.....	3	3	3	100·0	8·6	4·1	6·3
Naples.....	2	1	1	100·0	9·4	9·2	9·3
Italy (total).....	36	30	29	96·7	25·2	·9	8·5
Sicily (Messina).....	28	22	9	40·9	16·6	·5	9·1
Greece (Zante).....	2	2	2	100·0	8·7	4·8	6·7
Candia.....	12	10	6	60·0	16·8	5·5	9·5
Levant.....	3	3	13·5	8·5	10·4

The Seville oils, both as regards their freedom from acidity and the high percentage of genuine samples among them, prove to be superior to the famed Gallipoli oils. The acidity of some of the samples of Malaga oil was very high, but the average acidity was less than that of any of the Italian oils, except those from Monopoli, of which only three samples were examined. Among the Malaga oils there was a large percentage of adulterated samples. Taking the Spanish oils generally, although they appear from these results to be more liable than the Italian oils to be adulterated, yet, on the other hand, they are as a

rule decidedly more neutral, which, as regards lubrication and burning, is a very important point.

Amongst the Italian oils those from Gioja are distinguished for their acidity. The small number of adulterated Italian oils is worthy of note.

My analyses of the oils from Sicily quite confirms their reputation for inferiority. They are very largely adulterated, and as a rule decidedly rancid.

A few single samples from sources not named in the table have also been examined. Thus, some oil from Mitylene proved to contain as much as 30 per cent. of free fatty acid,

A sample labelled "Sfax Fine Olive Oil" gave the following results:—

Sp. gr. at 60° F.	0.9169
Free fatty acid (= oleic)	13.5 per cent.
* Rise of temperature with sulphuric acid of 97 per cent. strength.	43.5° C.
Percentage of KOH required for saponification.	19.38 per cent.
Melting point of fatty acids by } 28° C. and capillary tube method	28.5° C.

* The Elaidin required 310 minutes to solidify at 19° C., and was dark lemon yellow and soft after standing 24 hours at 19° C.

The oil showed no unusual tendency to dry when tested side by side with olive oil of known purity.

By Renard's process no Arachis oil was found.

By the Millian-Stoeck test no cotton oil was found.

The melting point of the fatty acids is quite abnormally high, and so also is the specific gravity, considering the large percentage of free fatty acid in the sample. No conclusions can be drawn, however, from the results yielded by this single sample. Another African oil, from Saffi (Morocco) gave quite normal results.

* See this Journal, 1886, 303 et seq.

NOTE ON THE USE OF POTASSIUM CYANIDE IN THE ESTIMATION OF COPPER.

BY GEO. E. H. ELLIS, F.C.S.

ASSAYERS in this section of the United States (Butte City, Montana) are in a somewhat unenviable position, for they have to work accurately, expeditiously, and, at the same time, cheaply. A copper assay (wet method) costs but a dollar, a silver and gold determination the same amount, while the value of a lead ore or of a silver ore is determined for the pitiable sum of half a dollar. These are the usual charges, but some assayers "run" three silver samples for a dollar, and wait a month or longer for remuneration for

their labours. Add to this the fact that a copper assay is supposed to take four hours for execution, and a silver one two, and it will be readily seen that lengthy, elaborate, or expensive methods of analysis, *e.g.*, brown iodide of potassium method, the electrolytic method, &c., are useless so far as we are concerned. In the assay of copper ores, therefore, we are confined to the determination by means of a standard solution of potassium cyanide, and I regret to say that some of our assayers (?) (and Butte City is the second largest mining camp on the face of the globe), after getting the copper into solution, render the solution alkaline with ammonia, filter off the precipitate (if any), and then titrate with the cyanide solution, utterly ignoring the fact that the amount of potassium cyanide used is no indication of the percentage of copper present if the ore carries zinc, iron, or other foreign metals.

Much has been written about the interference of zinc, iron, &c., but believing from experience that these results, though probably correct in direction, were not correct in degree, I determined to obtain further information by appeal to experiment. The influence of zinc was first determined, for most of our copper ores obtained at moderate depths carry more than "traces" of this metal.

The following solutions were prepared:—

(A.) 7.3104 grms. of pure copper were dissolved in a little pure nitric acid, the solution heated to small bulk, and then diluted to 3,000 cc.; 30 cc. of the copper solution, therefore, contain 0.73104 gm. of copper.

(B.) 121.5 (approximately) grms. of potassium cyanide were dissolved in 1,000 cc. of water.

(C.) 6.5035 grms. of pure zinc were dissolved in a small quantity of nitric acid; the solution was then heated to a small bulk and diluted to 10 litres; 1 cc. of the zinc solution, therefore, contains 0.00065035 gm. of zinc.

The mode of procedure was as follows:—30 cc. of the copper solution (A.) were taken, 150 cc. of water were then added, then varying quantities of the zinc solution (C.). 15 cc. of strong ammonia was afterwards introduced, and the blue solution nitrated with the standard potassium cyanide solution. The solutions were measured with pipettes graduated to $\frac{1}{20}$ cc., and each set of experiments was made on the same day, so that the results obtained should not be affected by the alteration in the value of the cyanide solution.

A large number of experiments were performed, and no difficulty was experienced in obtaining concordant results. The following are offered as being the most reliable:—

Composition of Solution.	Weight of Zn and of Cu.	Percentage Composition.	KCy required in cc.	Difference in cc.
30 cc. of Cu solution + 0 cc. of Zn solution	*073104 Cu Nil Zn	Cu = 100 Zn = 0	23.94	..
30 cc. of Cu solution + 1 cc. of Zn solution	*073104 Cu *00065035 Zn	Cu = 99.118 Zn = 0.882	23.93	- 0.01
30 cc. of Cu solution + 2 cc. of Zn solution	*073104 Cu *0013007 Zn	Cu = 98.252 Zn = 1.748	23.94	0.00
30 cc. of Cu solution + 5 cc. of Zn solution	*073104 Cu *00325175 Zn	Cu = 95.741 Zn = 4.259	23.95	0.01
30 cc. of Cu solution + 7.5 cc. of Zn solution	*073104 Cu *004877625 Zn	Cu = 93.745 Zn = 6.255	24.06	0.12
30 cc. of Cu solution + 10 cc. of Zn solution	*073104 Cu *0065035 Zn	Cu = 91.831 Zn = 8.169	24.50	0.56
30 cc. of Cu solution + 15 cc. of Zn solution	*073104 Cu *00975525 Zn	Cu = 88.227 Zn = 11.773	24.96	1.02
30 cc. of Cu solution + 20 cc. of Zn solution	*073104 Cu *013007 Zn	Cu = 84.895 Zn = 15.105	25.31	1.37
30 cc. of Cu solution + 25 cc. of Zn solution	*073104 Cu *01625875 Zn	Cu = 81.809 Zn = 18.191	25.48	1.54
30 cc. of Cu solution + 30 cc. of Zn solution	*073104 Cu *0195105 Zn	Cu = 78.934 Zn = 21.066	25.64	1.70
30 cc. of Cu solution + 35 cc. of Zn solution	*073104 Cu *02276225 Zn	Cu = 76.256 Zn = 23.744	25.75	1.81
30 cc. of Cu solution + 40 cc. of Zn solution	*073104 Cu *026014 Zn	Cu = 73.755 Zn = 26.245	25.85	1.91

Composition of Solution.	Weight of Zn and of Cu.	Percentage Composition.	KCy required in cc.	Difference in cc.
30 cc. of Cu solution + 80 cc. of Zn solution.....	·073104 Cu ·052028 Zn	Cu = 58·122 Zn = 41·578	28·96	5·02
30 cc. of Cu solution + 120 cc. of Zn solution.....	·073104 Cu ·075042 Zn	Cu = 48·366 Zn = 51·634	32·84	8·90
30 cc. of Cu solution + 200 cc. of Zn solution.....	·073104 Cu ·130070 Zn	Cu = 35·981 Zn = 64·019	39·76	15·82
30 cc. of Cu solution + 320 cc. of Zn solution.....	·073104 Cu ·208112 Zn	Cu = 25·995 Zn = 74·004	47·12	23·18
30 cc. of Cu solution + 400 cc. of Zn solution.....	·073104 Cu ·260140 Zn	Cu = 21·937 Zn = 78·063	52·53	28·59
30 cc. of Cu solution + 600 cc. of Zn solution.....	·073104 Cu ·390216 Zn	Cu = 15·778 Zn = 84·222	64·20	40·26
30 cc. of Cu solution + 800 cc. of Zn solution.....	·073104 Cu ·520280 Zn	Cu = 12·330 Zn = 87·680	79·20	55·26
30 cc. of Cu solution + 1,000 cc. of Zn solution...	·073104 Cu ·650350 Zn	Cu = 10·105 Zn = 89·895	92·50	68·56
30 cc. of Cu solution + 1,200 cc. of Zn solution...	·073104 Cu ·780420 Zn	Cu = 8·565 Zn = 91·435	96·80	72·86
30 cc. of Cu solution + 2,000 cc. of Zn solution = 22 cc. of AmHO (instead of 15 cc. as in all the other cases).	·073104 Cu 1·30070 Zn	Cu = 1·839 Zn = 98·161	123·0	99·06

From these results it may be concluded that the presence of 4—5 per cent. of zinc in the copper solution does not practically affect the correctness of the indications afforded by the potassium cyanide solution; but that when the percentage of zinc exceeds that amount, the indications of the standard solution are perfectly untrustworthy, and that consequently the zinc must be removed before titration is effected. When the percentage of zinc present was considerable, it was noticed that the change of colour of the solution from light blue to faint violet took place very slowly indeed.

It seemed also a matter of interest to determine whether the "copper value" of the blue solution altered on being kept exposed to air and to light for a considerable time. All the experiments performed showed that the blue colour in the ammoniacal solution at the end of three weeks required for its discharge practically the same volume of potassium cyanide solution as it did when first produced. For instance:

On June 1st a solution (A.) was prepared containing 20 cc. of solution of copper nitrate, 100 cc. of water, and 10 cc. of ammonia solution. The blue solution, which did not fill the flask, was then exposed to light until the 22nd June, when it was titrated and required 17·5 cc. of cyanide solution for the discharge of the colour.

Solution (B.), prepared and titrated on the 22nd with the same solutions, containing 30 cc. of copper nitrate solution, 150 cc. of water, and 15 cc. of ammonia solution, required 26·3 cc. of cyanide solution.

26·3 cc. for 30 = 17·53 cc. for 20.

As regards the standardising of the potassium cyanide solution, my experience seems to indicate that standardising should be performed *at least* once a week; a certain weight of copper which on the 6th of June required 24·8 cc. of cyanide solution needed 26·3 cc. of the same solution on the 22nd of the same month—an increase of 0·1 cc. per day.

I hope soon to be able to present to the Society a series of determinations upon the influence of varying quantities of iron on the amount of potassium cyanide required for the titration of solutions containing equal weights of copper. Present results show that the percentages obtained are always low when a considerable percentage of iron is present, owing probably to the retention by the precipitated hydrate of a portion of the blue ammoniacal compound.

ASSAYING AND HALL-MARKING AT THE CHESTER ASSAY OFFICE.

BY W. F. LOWE, F.I.C., F.C.S.

(Associate of the Royal School of Mines.)

THERE seems to be little doubt that the Chester Assay Office is descended from the old Chester Mint that existed as far back as the reign of Athelstan, but the charter of the company only dates back to the reign of James II. An old minute book of the Chester Goldsmiths' Company, however, dates back as far as 1523, and from this it is seen that the officers of the company had the power of testing (by touch) all articles of gold or silver sold in the city of Chester.

The process of assay by cupellation is the removal by the aid of fused lead oxide of all the constituents of an alloy with the exception of the so-called noble metals, gold and silver (and also platinum, if present). It is carried out by the addition of a suitable quantity of lead to the alloy, which is then placed on a hot bone-ash cupel, and heated in a current of air. The lead and also the other metals, with the exception of the gold and silver, oxidise, and the fused lead oxide takes up the other oxides as fast as they form and carries them down into the porous cupel until a button of pure gold or silver only is left. The process of cupellation is one of the oldest metallurgical operations there is any record of, for it is frequently mentioned in the Old Testament as the "refiner's fire." There is also no doubt that the Romans carried out the process on a large scale, for numerous pigs of lead have been found in this country bearing the sign "EX ARGENT" (ex argentate) showing that they had been desilverised, and assays of the lead prove this to have been the case.

To come down to a more recent date, a very full and complete account of the method of assay by cupellation, &c. is given in Sir John Pettus' translation of Lazarus Erckern's Book on Assaying published in 1683.

The modern methods of bullion assay will be found very fully described in Watts' Dictionary of Chemistry, Phillip's Metallurgy, Percy's Silver and Gold, Makin's Elements of Metallurgy, and also in the last edition of Muspratt's Dictionary of Chemistry.

The furnace used for cupellation is a muffle furnace, and, after having worked with many forms, we find that no furnaces are to be compared both for accuracy in assaying and for ease and comfort in working with Fletcher's gas furnaces. At Chester Assay Office a pair of these furnaces have been used for the last eight years, and have been found most satisfactory. The muffles are 9 $\frac{3}{4}$ in. by 5 $\frac{1}{4}$ in., and

each muffle is capable of cupelling 32 gold assays at a batch (*i.e.*, of taking eight cupels, each cupel taking four assays). With gold assays, they burn 75 cubic feet of gas per hour, but with silver assays, where only 20 assays are cupelled in a batch, and the temperature is much lower, they burn from 50 to 55 cubic feet per hour, and with the price of gas at Chester (3s. 4d. per 1,000) they cost 3d. per hour for cupelling gold and about 2d. per hour for cupelling silver.

Formerly a furnace similar to that described in Makin's *Manual of Metallurgy* was used; later this was replaced by a pair of furnaces similar to those used in the metallurgical laboratory of the Royal School of Mines, a description of which is given in Percy's *Silver and Gold*.

The gas furnaces are placed under a hood and are connected with the chimney of the furnace room by means of a cone damper which can be brought right down upon the loose iron chimney supplied with the furnace, or can be raised above it; this damper is very useful in regulating

Fig. 1.

the draft. At first there was some difficulty with the grids or upper part of the burners; these used to get red hot, and in a few weeks the slits in them would be nearly closed up so that the grids required continually renewing.

To prevent this, the body of the furnace was raised about half an inch above the burner, being supported on strips of asbestos cardboard at the corners. If the body is raised only very slightly above the burner, this heating is prevented, but it is an advantage to raise it as much as half an inch, so that in case of the passage for the flame round the muffle getting choked with soot, a bent iron rod can be inserted without putting out the furnace and cooling down the muffle. This choking only very occasionally takes place, but it is capable of spoiling any assay that may be in the furnace if it cannot be removed at once, as the temperature is lowered so considerably by it. The heating of the burners took place only when the furnace was kept burning for several hours together, and especially when the temperature was changed several times, as in cooling down before taking out silver assays and then heating up again for the cupellation of another batch. Since raising the body of the

furnace the grids last for months, only requiring renewing about once or twice a year. Another little precaution to be taken with these furnaces is to tightly wire the connecting india-rubber tube to the burner of the furnace, for after a time it is apt to get slack where it fits on to the burner, and when this happens the gas flashes back and takes fire at the small nozzle through which it passes before entering the box below the gauze and grid.

The muffles used have only a few small holes at the end, moderately high up; in fact, the muffles are supplied without any holes, and a few are made in them before being used. Muffles with slits in the sides are decidedly objectionable, as they crack much sooner, and silver assays done in them are not so uniform. After a muffle has been in use for some time it frequently cracks along the bottom, and this, if not noticed, will often cause trouble, as the assays which are in the cupels just over the crack leap or spurt, and are thus rendered worthless. The cause of this appears to be the reducing action of the fine jet of gas which, passing through the crack, acts on the absorbed oxide of lead in the cupel, and disengages gases just below the bottom of the molten assay. The cracks can be stopped with fireclay, or a thin piece of iron can be laid on the bottom of the muffle; but neither remedy is satisfactory, and it is better to put in a new muffle at once.

For silver assays, 10 grains are taken, but a special set of weights is used, divided into ozs., dwts., $\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{8}$ dwts., the 10-grain weight, representing the assay pound of 12 troy ounces, and the standard weight of 9.25 grains, representing 11 oz. 2 dwt., that being the legal standard for silver.

The balances employed are made by Oertling, and will indicate distinctly $\frac{1}{10000}$ of a grain; in fact, on such a balance, one milligramme puts the pan right down upon its supports, and the needle completely off the scale.

The weighed assay is placed in a little bag of lead, made by taking very thin sheet lead (laminated lead) cut to the proper weight (the piece then measures about $3\frac{1}{2}$ by $2\frac{1}{2}$ in.), and rolling this up into a little conical bag, like the bags used by grocers for holding moist sugar, &c. It is needless to say that each batch of lead is assayed for silver. The commercial laminated lead is quite pure enough for this purpose, as on an average the amount used for each assay contains only sufficient silver to raise the amount by 0.08 per thousand. The bags are kept on a shelf by the side of the balance. After being placed in the lead bag, the latter is folded up and is squeezed up into a very little ball, which is then ready for cupelling. 20 to 24 silver assays are cupelled at a batch, and several check or trial assays are cupelled at the same time, to determine the loss of silver by absorption into the cupel. At a proper temperature the loss appears to be due entirely to absorption, for the amount lost by the assays can be recovered from the cupels. If the temperature is too high there is also a loss due to volatilisation, and at the temperature at which gold assays are cupelled, and which is much higher than that employed for silver, there is some loss of silver by volatilisation. Silver can always be found in the fine dust of these furnaces, and the dust from the inside of an old iron chimney yielded 0.073 per cent. of silver and 0.00033 per cent. of gold.

The pure silver for checks as also the pure gold for the same purpose, we always prepare ourselves, and before using them compare them with assays from the trial plates supplied by the Mint. These trial plates are portions of those prepared at the Mint. A full and very interesting account of their preparation is given in the fourth Annual Report of the Deputy Master of the Mint, 1873.

The loss of silver in cupellation varies with the temperature, and at the temperature usually employed by the writer the loss is not more than 1 to $1\frac{1}{2}$ dwt. on the assay pound or about 4 to 6 parts per thousand, on a batch of 20 assays. With a batch of 24 assays it is rather more, about 8 parts per thousand, but with only about a dozen assays it can be reduced to $\frac{1}{2}$ dwt. per assay pound or about 2 parts per thousand.

The great advantage of the gas furnace is, that not only is this loss less than in the coke furnace, but it is also much more uniform, the checks in the front losing almost identically the same as those in the centre and back rows,

whereas with a coke furnace the loss is usually very much greater at the back of the muffle.

Great care must be taken in cooling down silver assays before removing them from the muffle, for the pure molten silver left on the cupel absorbs oxygen and this oxygen is given off as the assay cools and sets; and if the assay is cooled quickly the surface sets before the oxygen has been given off, then what is called "spitting" of the assay takes place; that is, a kind of arborescence is thrown up.

There is a curious effect often to be noticed when pure silver checks have been used without the addition of any copper. If the furnace has been turned down too quickly so as to make the finished assays spit, the buttons from the standard silver (*i.e.* alloyed silver) will have spit, whilst the pure silver checks will not have done so.

The assays after removal from the furnace are squeezed with a pair of pliers, brushed, and then weighed.

Gold.—The oldest method of testing the quality of gold was by the touch. This consisted in making a streak on a black stone, called a touchstone, and comparing it with a streak from a piece of gold of known composition called a touch needle. Erskern says that by this method a difference of half a carat (*i.e.* about 2 per cent.) can be detected, but it has been shown that a difference of several carats very frequently cannot be detected even by those accustomed to use the touchstone.

The process for the bullion assay of gold depends on the solubility of silver and the insolubility of gold in nitric acid. It was formerly considered that 3 parts of silver should be added to 1 part of gold in order that all the silver might be removed, and hence the process received the name of inquartation. It is now found that gold will part on the addition of 2 parts of silver to 1 of gold, but in assaying it is usual to obtain the alloy in the proportion of $2\frac{1}{2}$ parts of silver to 1 of gold.

Erskern describes this process very fully, and his description is very similar to the method in which it is still carried out, and a considerable amount of accuracy seems to have been obtained (to about 0.1 per cent.).

There are three different methods of reporting the quality of gold: (1) decimally; (2) in carats; and (3) in parts of the assay pound of 12 oz. troy.

The following table by Professor Roberts Austen shows the relationship of the three methods. It is usual, however, in employing carats, to weigh to the $\frac{1}{16}$ th of a carat grain.

				Excess Grains.	Decimal Equivalent.
				1	1736
				7.5	13021
				60	107116
				240	4176
				5,760	1,00000
Assay Pound.	Carat.				
	1	4	8		
1	24	96	768		

At Chester the unit weight employed is five grains, this represents 24 carats, but the assay can readily be reported decimally if required. The writer would prefer to employ a larger quantity, but the difficulty lies in being able to obtain a sufficient amount for assay without damaging the articles sent to be hall-marked. Many of these, such as rings, brooches, chains, &c., are very small.

In taking the assays from the articles, if they are large enough they are scraped with a steel scraper, and if the article is made in several portions a separate assay is made from each part. The smaller articles have small pieces cut off, as they are sent up unfinished. Not less than two assays are made if possible from a single lot of work, and where there is a large number of articles in one lot, a dozen or more assays may be made from it.

The weighed assay is placed in what is called a silver lead, that is a small conical bag of lead into which has been weighed the requisite amount of fine silver to form an alloy of $2\frac{1}{2}$ parts of silver to 1 part of gold. When a batch of 30 assays is ready they are each squeezed up to the size of a small bullet, and cupelled. The buttons are taken from the cupel with a pair of pliers, squeezed and brushed

with a fine wire brush, then flattened or datted as it is called on an anvil with a heavy round-faced hammer, both hammer and anvil being kept bright and polished, and are then rolled out into a little strip about three inches long. Each assay, after rolling, is placed on a tray of wire gauze over a large, solid flame Fletcher burner, and in this way the whole batch of 30 are annealed at one time. After the strips are cool they are rolled up into little coils called cornets, and they are then ready for parting.

Formerly the parting was done in flasks, the ones exhibited being some of the patterns used; the oldest is one that has not been in use for 60 or 70 years at least. The best for this purpose are the long-necked parting flasks, but the labour of filling and emptying is very great when about 60 gold assays are made per diem, and in order to simplify the operation I designed the apparatus shown, which is described in the Chemical News, and also in the last edition of Mitchell's Manual of Assaying.

Fig. 2.

The apparatus consists of a porcelain basin $8\frac{1}{2}$ in. in diameter, having a capacity of 50 oz.; a porcelain cover perforated with 30 holes, each hole being numbered with black enamel; and a number of glass tubes. The tubes are made to slip loosely through the holes in the cover, and in order that they may not come against the bottom of the basin they are bulged out into a ring near the centre of the tube. The tubes we are using at present have three small holes in the bottom and another hole in the side, about 1 in. from the bottom; but I am having some tubes made with two fine slots at right angles to each other, and extending about 1 in. up.

I am also having a glass hood condenser made which will fit into a depression in the cover, the cover being made so [] to receive it.

The method of using the apparatus is this:—Two of the basins containing a sufficient quantity respectively of weak and strong nitric acid are heated over two of Fletcher's radial burners, the basin of weak acid being covered with the perforated plate carrying the tubes, and the strong acid being covered with an ordinary dinner plate. The assays, which are flattened, &c. whilst the acid is heating, are dropped into the tubes, and as soon as the action of the acid has ceased the cover is lifted off by means of a metal crutch covered with india-rubber, and the tubes are dipped

Fig. 3.

into a basin of distilled water. The whole 30 being thus washed at one operation, they are then transferred to the basin of strong acid (sp. gr. 1.28) and are boiled briskly for half an hour, the time being noted on a small slate hung at the side of the draught closet.

It is very necessary that the boiling should be brisk, as otherwise a much greater surcharge will be found, and it is curious to note that this was known at the time Erekern wrote, for he says, "Take notice also that you may cause the last aqua fort to work in great bubbles that the roles may become clean."

After boiling in the second acid, the tubes are lifted by the cover and are dipped into distilled water and allowed to drain. Each tube is then taken out in order and is plunged over head in a basin of distilled water, so as to completely fill the tube. The tube is then inserted over a small porous crucible and the assay allowed to fall through the water into the crucible. The crucibles are drained and are then annealed, *i.e.*, ignited in the muffle, when the assays are ready to weigh. The use of somewhat similar perforated tubes had been tried for this purpose some time ago, but was given up it is said from the difficulty which was found in transferring the assay to the crucible. In the method described above there is no difficulty whatever in doing this, and when the writer designed this apparatus he had no knowledge that tubes of this kind had been used before.

This apparatus has now been in use at the Chester Assay Office for the last 10 years, during which time at least 90,000 assays have been made with it, and has given every satisfaction. Its great advantages are that all the assays are under precisely the same conditions, it is a very great saving of labour and time, much less nitric acid is required, and it requires no attention until it is time to take off the assays; in fact it combines nearly all the advantages of the costly platinum cups and boilers used for a similar purpose with a very moderate cost.

The only special precautions to be taken with it are: (1) to have the first acid sufficiently dilute; (2) to see that the second acid boils properly; and (3) not to boil the second acid longer than about half an hour, as the best results are obtained under these conditions.

Pure gold check assays are employed with each batch of assays, for in parting gold and silver with nitric acid there is always a slight surcharge with the higher standards and a slight loss with the lower, and this has to be allowed for in weighing up the finished assays. In the process described

the surcharge on 22 carat or $\frac{916.6}{1,000}$ gold is usually from 0.06 to 0.07 per 1,000. On 15 carat or $\frac{625}{1,000}$ gold and on 18 carat or $\frac{750}{1,000}$ gold it is usually nil, but if the acid has not been boiling well, there will be a surcharge. With 9 carat or $\frac{325}{1,000}$ gold there is a slight loss, usually about 0.06 to 0.08 per 1,000. Under the proper conditions both surcharge and loss are very regular. The surcharge is due to the retention of silver in the cornets, and this was known as far back as the time of Erekern, for he recommends the use of check assays.

The pure gold used in check assays is prepared by dissolving fine gold (assay bits) in aqua regia, evaporating off the acid, and diluting very largely with water to allow all the silver chloride to settle. The clear solution is then siphoned off, and the gold precipitated with oxalic acid. The precipitated gold is boiled with hydrochloric acid, to free it from any traces of silver chloride. It is then washed with hot water, dried, and fused under bisulphate of potash.

In preparing some pure gold in this way from 5 oz. of assay bits, 3.858 grs. of AgCl were obtained. This is equal to 2.9 grs. of silver; so that the amount of silver present in the assay bits was equal to 1.23 parts per thousand.

In cupelling gold there is always a slight loss, due to absorption into the cupel. It is usually stated that this loss is greater with the lower than with the higher standards. This, however, does not appear to be the case, for the following table give the results of some assays made of cupels which had been used for different standards, and it will be seen that the absorption is almost identical.

Standard.	Weight of Gold obtained from 1 Cupel (= 4 Assays of 5 grs. each).	Absorption per Thousand.
9 carat, or $\frac{375}{1,000}$	0.014 grs.	0.7
Do. do.	0.014 "	0.7
15 carat, or $\frac{625}{1,000}$	0.014 "	0.7
Do. do.	0.015 "	0.75
18 carat, or $\frac{750}{1,000}$	0.014 "	0.7
Do. do.	0.015 "	0.75
22 carat, or $\frac{916.6}{1,000}$	0.014 "	0.7

The above were all cupelled on different days, so that the temperature of the furnace would not account for this regularity; but as the amount of lead used is the same for all standards, this, most probably, is the cause of the regularity.

The number of assays made last year at the Chester Assay Office, from articles sent to be hall-marked, was 25,100, of which more than half were gold.

PROPOSED UNIFICATION OF NOMENCLATURE IN ORGANIC CHEMISTRY. (PARIS.)

The following is the text of the resolutions adopted at the International Chemical Congress recently held in Paris (this Journal, 1889, 656).

Nomenclature of the Non-saturated Derivatives of the Fatty Series.—"The letters *a* and *b* shall designate the two atoms of carbon bound together by multiple links, in the case of bi-substituted derivatives; in the case of tri-substituted derivatives the designation may be omitted, provided the two radicals united to the same atom of carbon be named first."

Improvements in Filters. M. Negro, London. Eng. Pat. 11,357, August 7, 1888. 8d.

Two annular tubes of perforated metal or wire-work enclose between them the filtering agent, which may be paper, asbestos, or other of the substances commonly used for such a purpose. The filter so formed is fitted by means of a screwed socket in the interior of a conical vessel forming the reservoir for the unfiltered substance, the lower end of which forms the outlet for the filtrate.

—C. C. H.

An Improved Apparatus for Ice-making and Refrigerating. A. Glasson, London. Eng. Pat. 12,008, August 20, 1888. 8d.

THE improved refrigerator belongs to the type generally known as "ammonia absorption" apparatus. A is the generator, heated preferably by gas, and vaporising the concentrated solution of ammonia it contains. The vapour rises through the rectifier tubes I into the bonnet G'; the water condensed returns through pipe J, and the vapour passes on, is condensed in worm L, and, by means of tube S, delivered into receiver R' supplying the freezing cell S'.

Vaporising again in jacket U, it abstracts heat from the water contained in S', kept in motion by stirrer Z, and, passing through pipe X' into absorber M, meets with a fine spray of weak liquor delivered from A through tube N', cooled in worm P, is absorbed and again let down into A when required to be re-distilled.—C. C. H.

Improved Method of and Apparatus for Centrifugally separating Solids and other Matters from Liquids. W. Hicks, London. Eng. Pat. 2528, February 13, 1888. 8d.

A NUMBER of arms or chambers radiating from a common centre, provided internally with partitions so as to form a zigzag passage from the upper to lower part, are fixed to a vertically revolving shaft. The outer extremities are fitted with sliding valves, so that the ends of the horizontal chambers formed by the partitions can be opened; the lower ends of all the chambers formed by the partitions communicate with a common overflow pipe next the rotating shaft. The action is as follows:—Liquid containing solid matter is introduced into the upper part of the chambers, the solid matter it contains by centrifugal force collects on the periphery and may be discharged from time to time through the sliding valves, whilst the liquid passes to and fro from centre to periphery and *vice versa*, and so on through the entire length of the passage in the chambers, and finally overflows in a clarified condition into the common outlet pipe. A modification is also shown, in which the liquid is forced in, and so urged filtration or separation secured.—C. C. H.

II.—FUEL, GAS, AND LIGHT.

Experiments on the Manufacture of Oxygen in Gasworks, and the Result of its practical Application to the Purification of Coal Gas. W. A. Valon. The Gas World, 1889, 715—719.

IN a previous paper the author has given an account of experiments in the purification of gas by means of oxygen in conjunction with "oxide" or lime. When oxide alone is employed and a small quantity of oxygen is mixed with the crude gas, the oxide is revived *in situ*, the life of the purifier is lengthened, and the cost of labour is considerably diminished. The advantages of using oxygen are still more marked when lime, in quantity sufficient to remove the carbon dioxide, is employed in purification; not only the carbon dioxide but the whole of the sulphur (sulphuretted hydrogen) and some of the sulphur compounds are removed, the latter being abstracted with perfect certainty, and the lime having no unpleasant odour either when partially or completely spent.

The oxygen is made by Brin's process, and the necessary apparatus is fully described. The barium oxide is heated at a constant temperature in steel retorts placed in ordinary gas retorts, and by the aid of an automatic arrangement for reversing the valves, devised by Mr. Murray, the process may be described as practically automatic. The requisite quantity of oxygen is mixed with the gas by means of a proportional meter, devised by W. G. Hicks, which automatically and accurately regulates the percentage of oxygen necessary for purification, and is so arranged that the quantity added can be increased or decreased at will.

In experiments made at the Ramsgate works, a series of four purifiers (1, 2, 3, 4), 14 ft. × 14 ft., were each charged with 12 yds. of slacked chalk lime, not 60 per cent. of

which was caustic, and the gas, previously mixed with 0.6 per cent. of oxygen, passed through three of the boxes. The test for foulness is carbon dioxide in equal quantities at the inlet and outlet; with Sheard's apparatus a test can be made in a few minutes. The foul gas at the inlet of the first purifier contained on the average a trifle under 1 per cent. of carbon dioxide and 600 grains of sulphuretted hydrogen per 100 cubic feet. For the first six days the gas at the outlet of No. 1 was free from both sulphuretted hydrogen and carbon dioxide, and on the seventh day it contained only 98 grains of carbon dioxide and 110 grains of sulphuretted hydrogen; the inlet at the foul main showed at the same time 700 grains of carbon dioxide and 600 grains of sulphuretted hydrogen, and the sulphur (sulphur compounds) in the purified gas was under 6 grains. On the seventh day No. 2 commenced to work, and no carbon dioxide or sulphuretted hydrogen were present at the outlet until the 14th day. On the 14th day No. 3 commenced to work, and, 29 days after No. 1 was started, the gas at the outlet of No. 3 contained only 5 grains of sulphuretted hydrogen and not a measurable trace of carbon dioxide, No. 1 not yet being quite exhausted, although having passed more than 8 million cubic feet of gas. No. 1 was finally thrown out on the 40th day, 9 million cubic feet of gas having passed through it. The gas thus freed from sulphuretted hydrogen and carbon dioxide completely, and from sulphur compounds to a considerable extent, was, therefore, more than half a million cubic feet per yard of caustic lime, and the total sulphur in the purified gas did not at any time exceed 8 grains per 100 cubic feet.

These facts prove beyond doubt (1) the instantaneous action of oxygen; (2) the fixity of the sulphur in the lime; (3) that with oxygen a greatly reduced area is required; (4) economy in lime; (5) economy in labour; (6) simultaneous and perfect purification from sulphuretted hydrogen and carbon dioxide; (7) easy and absolute control of the sulphur compounds without trouble or anxiety; and (8) complete immunity from anything objectionable while carrying out the operation.

Experiments which were made to ascertain the effect of air on the illuminating power gave the following results:—The gas at Ramsgate has averaged for years past, with oxide purification and 1 per cent. of air, 13.5 candles, the coal used being Pelaw Main, and the make over 10,000 cubic feet per ton; 2½ per cent. of New Boghead or Tyne coal are added to bring the illuminating power up to 15.5 candles. Since lime and oxygen have been employed the illuminating power has ranged between 16.5 and 17.3 candles, and no coal whatever has been used, so that, allowing that the increase of one candle is due to the removal of 1 per cent. of carbon dioxide, the difference of 2½ candles may be credited to the use of 0.6 per cent. of oxygen and the discontinuance of 1 per cent. of air.

The effect of various quantities of air on the illuminating power was also carefully examined, and it was found that whilst with 0.6 per cent. of oxygen the illuminating power is 17 candles, when 2½, 3, and 5 per cent. of air are added instead, the illuminating power falls to 13.45, 13.04, and 10.09 candles respectively.

Comparative experiments with 3 per cent. of air in the one case and 0.6 per cent. of oxygen in the other, proved beyond doubt the value of oxygen over any possible system of air purification, in economy of space, lime, and labour, although an explanation of the cause of this difference cannot yet be given. Purifiers which, when pure oxygen was used, reduced the percentage of sulphur enormously, ceased to so reduce it directly air containing the same percentage of oxygen was used. And after a short time they actually let the gas issue more impregnated with sulphur compounds than it was when it entered the purifiers; and when the air was stopped and pure oxygen again admitted, the bad effect immediately ceased, and after an hour or so, when the oxygen had had time to spread through the material, the purifiers began to do good work again and to reduce the amount of sulphur.

With regard to the commercial and practical advantages accruing from the use of oxygen, the author asserts that, even where there is unlimited space for purification, or where the works are not under the operation of the Sulphur

Clauses Act, the avoidance of the use of cheap oxygen is an unjustifiable extravagance. The cost of providing, erecting, and maintaining the oxygen plant is discussed in some detail, and the saving from the employment of oxygen is estimated as follows:—The average cost of purification where companies are placed under the Sulphur Clauses Act is 3*l.* 15*s.* per 1,000,000 cubic feet (Field's analysis). The same work in conjunction with oxygen, but not including the cost of the oxygen, is 1*l.* 15*s.* The total cost, except the interest on plant, of 0.6 per cent., or 6,000 cubic feet of oxygen at the higher figure of 2*s.* 6*d.*, would be 15*s.* (a high estimate), and the interest on capital in providing oxygen plant at 10*l.* per million at 10 per cent., 1*l.* Balance in favour of oxygen, 5*s.* If to this sum the interest (3*l.* 15*s.*) on capital due to saving one-half the space and plant required under present system (*i.e.*, 50*l.* per million at 7½ per cent.), and the average cost (6*l.* 5*s.*) of 1½ candles in illuminating power at 1*l.* per candle, are added, the saving per million cubic feet is found to be 10*l.* 5*s.* Even if the interest (3*l.* 15*s.*) on capital saved is not taken into consideration, it still leaves 6*l.* 10*s.* per million to the credit of oxygen.

It is stated in conclusion that the economies of oxygen purification have been designedly understated, the saving claimed having been greatly exceeded at Ramsgate. It is sufficient for the author's purpose to make it clear that the system is self-supporting under all conditions where gas must be purified, and leaving such a margin as to recommend its adoption by all gas companies and corporations. (This Journal, 1889, 82.)—F. S. K.

PATENTS.

An Improvement in Fuel Gas Burners. The Gas Patents Syndicate, Limited. From J. B. Archer, Washington, U.S.A. Eng. Pat. 8560, June 11, 1888. 6*d.*

A HORIZONTAL pipe conveying air is terminated by an elbow piece, through the centre of which a smaller pipe is inserted to convey the fuel gas. A movable plug on the gas pipe serves to spread out the issuing gas, and a globular cap on the air pipe provides for a due admixture of gas and air before leaving the burner. A detailed drawing accompanies the specification.—G. H. B.

Improvements in Gas and Coke Producers and in the Apparatus for Collecting the By-Products therefrom. T. Nicholson, Hucknall Torkard. Eng. Pat. 9239, June 25, 1888. 6*d.*

ABOVE a coal or coke furnace is placed a generator or producer having a perforated bottom and sides. A blast of air is admitted to the furnace below, and the gaseous products from thence play through the perforations in the sides and bottom of the producer upon the charge of fuel within. The gaseous products from the furnace do not rise directly to the producer, but are first conducted to the rear of the apparatus, and are then, for their better distribution, led forward into a heat chamber immediately below the producer. The gas extracted from the charge of fuel in the producer is scrubbed with gas liquor in suitable scrubbers, and then led through a serpentine condenser. Lastly, the coke remaining in the producer is treated with wet steam, which is said to harden it and to remove its nitrogen and sulphur.—A. R. D.

The Generation of Gaseous Fuel and the Combustion thereof in Steam Generator Furnaces. The Gaseous and Liquid Fuel Supply Co., Limited, Manchester, and B. H. Thwaite, Liverpool. Eng. Pat. 10,224, July 14, 1888. 8*d.*

FROM an ordinary boiler flue the firebars are removed, and the fuel is allowed to rest upon a floor of refractory hollow bricks or pipes laid on the bottom of the flue. Below the ordinary door is placed another door for clinking and other purposes. Attached to the back of this, but at an interval of a few inches from it, is a refractory block through which a mixed blast of air and steam is supplied to the fuel lying on the floor, the few inches of space between the door and the block serving as a distributing chamber

for the said blast. The combustible gases produced by the decomposition of the fuel are met as they pass the furnace bridge by an independent air supply previously heated by traversing channels formed in the hollow floor supporting the fuel. For about 5 feet from its front end the flue is provided with a specially shaped refractory lining, which is raised to incandescence and prevents the deposition of carbon. A nest of open brickwork at the rear end of the flue also becomes highly heated and prevents any combustible gases from passing away unconsumed.—A. R. D.

Improvements in or relating to the Obtaining of Inert Gases.
L. Mond and G. Eschellman, Northwich. Eng. Pat. 11,294, August 4, 1888. 4d.

GASES containing oxidising or reducing constituents, or both, are deprived of these by being passed through oxide of iron or manganese of a suitable degree of oxidation heated to from 300° C. to 400° C. The oxide of iron or manganese that has been employed for eliminating an oxidising constituent may be revived for further use by being utilised to remove a reducing gas, or *vice versa*; or the process may be made a continuous one by taking care that gases of opposite tendencies are present in such proportions as to neutralise one another.—A. R. D.

Improvements in Gas-producing Apparatus in which the Carbonisation of Coal is continuously Effected. A. Elliott, Ludlow. Eng. Pat. 11,443, August 8, 1888. 11d.

AN open hopper kept filled with coal is connected by a vertical pipe with the horizontal retort which widens out towards the discharging end to allow for expansion of the coal during carbonisation. The gases are prevented from returning through the hopper by a sliding valve, which is only opened when a charge of coal is let down. The coal is moved forward in the retort by means of a scoop which can be moved forwards and backwards on an arm passing through the retort lid. The coke is received from the discharging end of the retort in a cylinder which revolves air-tight against a suitable face-plate on the retort, and is discharged by rotating the cylinder. The exit for the gas rises from the discharge end of the retort. Means for giving automatic motion to the various parts is described, and a number of retorts may be worked simultaneously. The specification is accompanied by drawings, which should be consulted for details.—G. H. B.

Obtaining Useful Products from Refuse or Residues of Gas Purifying, and Apparatus therefor. C. Dubois, Marseilles, France. Eng. Pat. 7653, May 7, 1889. 6d.

THE old or refuse materials which have been employed in the purification of lighting gas are heated in a rotary retort and at the same time treated with steam, superheated or otherwise. The sulphur is volatilised, and any cyanogen compounds present are decomposed with formation of ammonia. These products are separated and recovered by whatever means may be found most suitable.—A. R. D.

An Improved Apparatus for Manufacturing Carburetted Air Gas. G. P. Armstrong, London. From G. Jaunez, Paris, France. Eng. Pat. 7854, May 10, 1889. 6d.

THIS apparatus is to be worked on the same principle as that patented by Moussard in France, December 27, 1869, No. 88,263. It is claimed, however, to be less complicated, as all the parts are reduced to their simplest form. Liquid hydrocarbon is vaporised by heat and caused to pass through a Giffard's injector, where its expansive force is employed to draw in the air to be carburetted. A gas holder forms part of the apparatus, and the lower portion of this is utilised as a supply cistern for the hydrocarbon. It is situated below the injector or carburetter, so that any condensed liquid may flow back to the cistern. From the body of the holder a pipe passes downwards conducting gas to a burner, over which is placed a lenticular vaporiser. The

hydrocarbon flowing by gravity from the supply cistern above, is here brought to a state of vapour, and passes upwards as such to the carburetter. Leaving this latter mingled with air it goes forward to the holder, and thence through a suitable pressure regulator to be distributed as required.—A. R. D.

Process for Generating Gases known as Water-Gas and Producer-Gas. J. von Langer and L. Cooper, Leeds. Eng. Pat. 8192, May 16, 1889. 4d.

IN the usual process of making water-gas a mass of fuel in a generator is alternately submitted to the action of a blast of hot air from the bottom, and of a blast of steam from the top. The present improved process differs from the above by admitting both blasts at the top of the generator. It is claimed that a much higher proportion of water-gas is obtained and cheaper kinds of fuel can be employed. The same principle of downward direction only is also applicable when producer-gas alone is required, but in this case a reduced quantity of steam is admitted at the top, and a supplementary supply of heated air is introduced half-way down the mass of fuel.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

New Occurrences of Ozokerite. B. Lach. Chem. Zeit. 13, 831.

OZOKERITE for the cerasin industry is still obtained from Galicia, but new deposits are always being sought for. Ozokerite is known to be found in the Caucasus, and there are reports more or less fanciful from North America of deposits of white ozokerite miles in length being found.

The author having had samples submitted to him, has examined them by his process (Chem. Zeit. 9, 905; this Journal, 1885, 488) with the following results:—

Caucasian ozokerite resembles an inferior Galician variety. Melting point of crude substance 68° C. Treated with 20 per cent. of fuming sulphuric acid it yields 58.1 per cent. of second quality. Cerasin: melting point = 68.5° C. Volatile portion, 1.8 per cent.

The crude substance has a repulsive odour, is worked with difficulty in quantity, becomes stiff in the basin, and presses extremely badly. The price is at present too high, and until greater demand arises and the transportation be accomplished, the Galician ozokerite production will make very strong competition.

North American ozokerite, Colorado. Here extensive mines of an ozokerite-like substance are found, the supply of which is hindered only by the transport difficulty. On being tested, however, it proves useless for the production of cerasin. The material is supplied in cakes 36 × 20 × 6 cm. in dimensions. It is a dull black hard substance, smelling of catechu, and proving brittle and pulverisable. Care must be taken in melting it at 95° C., or violent frothing may occur from the presence of traces of water.

The analysis shows—

Melting point of crude substance 76.4° C.
" " treated " 76.5° C.

Treated by the aforementioned process no cerasin is obtained. Even when heated to 300° C. it will not filter in the slightest through filter-paper, although it is quite a thin fluid. Subjected to distillation it gives the undernoted results:—

	Per Cent. (by difference).
Paraffin and oil.....	90.60
Loss in gas	2.12
Loss in water.....	2.69
Residue	5.28

It commences to distil at 360° C., when nearly 3 per cent. of oil setting at 30° C. comes over. At a much higher temperature it runs over and distils steadily, giving a very fair crude product for paraffin extraction.

Consequently this substance is suitable for paraffin making and is absolutely useless for the cerasin industry.

The price is at present disproportionately high.—D. A. S.

Recovery of Tar and Ammonia in the Manufacture of Coke.
Stahl u. Eisen, 1889, 9, 482.

GREAT progress has been made in plant for condensing the tar and ammonia formed in the manufacture of coke, and it has been found that by condensing it the quality of the coke has not deteriorated. The Hoffmann-Otto ovens have proved excellent, and bee-hive ovens have also been used. In the water condensers not only the fluid tar but also much viscid tar is deposited, so it is advisable to make use first of air condensers which consist of large chambers with sheet-metal partitions between which the gases have to travel zig-zag, and thus deposit most of the tar and coal dust. After leaving the water-condensers the gases are passed through washers to remove the remainder of the tarry products. Since only 11 to 14 per cent. of the nitrogen in the coal are converted into ammonia, numerous attempts have been made to increase the yield. It has been proved in practice that instead of being diminished, as hitherto supposed, the yield is increased by employing a higher temperature, and the introduction of hydrogen into the coke ovens still further increases the yield. As hydrogen is too expensive, dissociation of water in the ovens has been tried, but the loss of coke in consequence is too great. The use of lime is also unsatisfactory, as the quality of the coke is deteriorated.

A greater yield of tar can be obtained by keeping the upper part of the ovens cool, but its quality is deteriorated owing to the decrease in the light oils. The tar is sent away for distillation, but the ammonia liquors are almost always worked up at the coke factories, generally into ammonium sulphate.—E. E. B.

Discovery of New Petroleum Wells near Baku.

A REPORT, dated the 22nd August last, has been received at the Foreign Office from P. Stephens, British Vice-Consul at Batoum, stating that news had been received in Batoum on the previous day to the effect that eight new fountains had been discovered in the naphtha-producing territory of that district, the combined output of which, at the present rate of supply, could approximately be estimated at 16,000 tons per diem, in consequence of which the price of crude oil at Baku had decreased from $\frac{1}{2}d.$ to $\frac{3}{4}d.$ per gallon, and a further fall was expected.

"Peat" Candles in South America.

"PEAT" candles are not made of peat, but of the paraffin that is distilled from peat in Brazil, where it is more plentiful even than in Ireland. According to *The Commercio des Amazonas*, John Grant and Co. are now having machinery installed at their works capable of producing 80 tons of peat paraffin a month. They are also extracting from the turf a valuable lubricating oil. They employ 300 workmen, and have 33 boilers with purifiers, stills, refrigerators in their plant.—*Engineering and Mining Journal*.

Petroleum in the Canadian North West.

THE *Canadian Gazette*, in its issue of August 8th, publishes the following:—

Interesting particulars of the rich find of oil in the North-West reached Ottawa on July 23rd in a letter received by Alfred Patrick, late clerk of the Dominion House of Commons, from his son, Major Allan Poyntz Patrick, Dominion Topographical Surveyor, of Calgary. The letter says:—"For 11 weeks we have been prospecting among the mountains for coal-oil deposits. I am happy to say we have been eminently successful. We have located a

considerable quantity of oil land, some on the eastern slope, and some on the British Columbia side. So soon as we felt perfectly certain as to the importance of our find we had several samples assayed. The result gave 91 per cent. lubricating oil, 5 per cent. heavy oil, 1 per cent. water, and 3 per cent. foreign matter. This is the best oil ever discovered, and far ahead of the Pennsylvanian oil-fields. There is plenty of head, the flow being about 4,500 feet above the sea level, and the crude oil can be run off in pipes any distance. It is the greatest find ever known. All the oil lands are within easy distance from the railway." The letter further states that arrangements are being made for developing the find, which, if correctly reported, adds immensely to the treasure to be expected from the North-West.

PATENTS.

Improvements in and Relating to the Manufacture of Acetic Acid and its By-products. R. Weiss, Zossen, Germany. Eng. Pat. 9835, July 6, 1888. 6d.

THESE improvements refer to the distillation of wood, peat, brown coal, or other organic substances, for obtaining carbon and various volatile products, notably acetic acid. It is proposed to introduce into the retorts a current of heated water or generator gas, or in fact any gas free from oxygen and containing carbonic oxide. This materially aids the evolution of the volatile products, and is said to largely increase their yield by removing them quickly from contact with the residual heated carbon, which is apt to promote their decomposition.—A. R. D.

Improvements in Vertical or Inclined Retorts for Distilling Shale, Coal, and other Analogous Substances. J. Jones, Dabuneny. Eng. Pat. 9893, July 7, 1888. 8d.

IN order to facilitate the discharge of the contents of the retort, the lower part is built so as to incline downwards to the discharge orifice, which may be closed by a sliding door as well as by an ordinary retort door. A suitable motion of a shovel applied at the bottom of a retort of this construction will cause the whole contents to descend evenly through the retort. A further claim refers to the employment of fireclay blocks having a feather and groove joint all round the block, of which the retort is to be constructed. The specification is accompanied by drawings.—G. H. B.

Improved Coating of Preservative Material for Iron, Steel, and other Structures, or for Coating the Bottoms of Iron and Steel Ships or other Vessels, and Process of Manufacturing the same and other Products from Gas Tar. J. H. Eastman, Liverpool. Eng. Pat. 10,192, July 13, 1888. 4d.

See under XIII., page 715.

IV.—COLOURING MATTERS AND DYES.

On Mononitroso- and Dinitrosomaphthoresorcinol. S. v. Kostanecki. Ber. 22, 1342—1347.

NEITHER the resorcinol of the naphthalene series nor its derivatives have been hitherto known. The author describes some compounds obtained from hydroxynaphthoquinone, $C_{10}H_5O_2$, $OH(O : O : OH = 1 : 4 : 2)$, belonging to this class of bodies.

Hydroxynaphthoquinonemonoxime, $C_{10}H_5(O.NOH)OH$, *Mononitrosomaphthoresorcinol* is obtained by treating hydroxynaphthoquinone (1 mol.) dissolved in caustic soda (2 mols.) with a solution of hydroxylamine hydrochloride (1 mol.). The yellowish-red solution turns to an olive-green, and on addition of acid a light yellow precipitate is formed, possessing all the properties of a nitrosophenol. Recrystallised from glacial acetic acid it forms yellowish

needles, decomposing at 180° C. with evolution of gas. To obtain a pure product it is essential to work with reagents free from iron. This body is practically insoluble in cold or hot water and ether, easily soluble in alcohol, caustic soda and carbonate of soda. Ferrous salts produce in its alcoholic solution a green lake, ferric salts a dark brown one. Cobalt salts produce a dark yellow; nickel salts a scarlet red precipitate. The mononitrosophthaloresorcinol dyes mordanted fibres. Olive-green colours are obtained with iron mordants and scarlets with nickel mordants. The latter are, however, not fast to boiling soap solutions.

Monochloromononitrosophthaloresorcinol—

Chloronaphthalenic acid—

is acted upon by hydroxylamine in the same way as hydroxynaphthoquinone, yielding finally a chlorinated product which, after recrystallisation from glacial acetic acid, forms yellow needles, decomposing at 178° C. It dyes mordanted fibre.

Dinitrosophthaloresorcinol, $C_{10}H_4(O.NO)_2$.—If one molecule of the mononitroso-compound and one molecule of sodium nitrite be dissolved in dilute caustic alkali and poured into dilute acid, a light yellow crystalline precipitate is formed, which after recrystallisation from alcohol, forms long plates nearly white and decomposing at 165°. It crystallises with one molecule of water and dyes mordanted fibre darker than the mononitroso-compound. On oxidation with nitric acid phthalic acid is formed. On reduction with tin and hydrochloric acid Merz and Weith's naphthalenic acid—

was obtained.—A. L.

On Colouring Matters which Dye Mordanted Fibres.

St. v. Kostanecki. Ber. 22, 1317—1333.

COLOURING matters having the character of phenols dye fibres mordanted with oxides, if two hydroxyl-groups are in the ortho-position. As a further instance that this theory is correct, the volatile nitropyrocatechin (nitrocatechol)—

was examined, the result being that one more proof for this theory was obtained. It produces orange shades with aluminium mordants, whilst its non-volatile isomeride yields a light yellow under the same conditions. Nitrosophenols act in the same way if they are orthoquinone-oximes. Several similar compounds were examined.

Anthraquinone-oxime—

can be considered a para-nitrosophenol, and does not form dyes with metallic oxides.

Phenanthrenequinone-oxime—

is an ortho-compound, and acts as a dye towards fibres mordanted with oxides.

Retenequinone-oxime—

produces green shades with iron mordants.

Orthoquinonedioximes form dyes with oxide mordants.
—*Orthonaphthalenedioxime—*

produces brown shades with iron or cobalt mordants.

Orthobenzenetetroxime—

forms dark browns with iron mordants.

The isomeric para-compounds, as *p*-naphthalenedioxime—

and

p-benzenedioxime—

do not form dyes with oxide mordants.

Orthohydroxyquinones form dyes with oxide mordants.
The dioxime of dihydroxyquinone—

was proved to be a colouring matter in that sense as well as the hydroxynaphthoquinone-oxime, whilst the isomeride of juglonmonoxime, which is not an ortho-compound, does not act as a dye.

Orthohydroxyquinones are not all dyestuffs. Experiments with hydroxythymoquinone proved a failure, whilst the tests with *o*-hydroxynaphthoquinone were successful,

as well as those made with Mylius' hydroxyjuglone. Far stronger colours are, however, obtained with such bodies, which contain this complex of atoms twice.

Dihydroxyquinone—

Chloranilic acid—

Nitraulic acid—

and

Rhodizonic acid

are all capable of dyeing upon oxide mordants.—A. L.

On Para-Diamidodiphenylpiperazine and the Formation of Colouring Matters from it. E. Tellmann and C. Schleich. Ber. 22, 1387—1389.

PARAMIDOPHENYLPYPERIDINE forms colouring matters, analogous to those obtained from paramidodimethylaniline. The authors examined the *p*-diamidodiphenylpiperazine in the same direction. It was prepared by heating 100 grms. of aniline with 100 grms. of ethylene bromide on the water-bath; a violent reaction sets in and the whole mass solidifies. Then 110 grms. of ethylenebromide were added and the mass heated to 130°—140° C. in the air-bath, whilst as much caustic potash was gradually added as would saturate the whole of the bromine. After several hours' boiling the organic compounds solidify. After washing with water they are distilled with steam to remove the excess of ethylene bromide and then treated with hot alcohol, by which the impurities are dissolved. The yield from 100 grms. of aniline was 90—100 of pure base. The nitrosation was performed in the same way as Morley describes, and the nitroso product without further purification was reduced with stannous chloride and hydrochloric acid. After precipitating the tin by sulphuretted hydrogen the hydrochloride of the diamido base was obtained in colourless prisms, crystallising with 4 mols. of water, $C_{16}H_{20}N_4(HCl)_4 \cdot 4H_2O$. On oxidation with 2 mols. of phenol or naphthol by ferric chloride, blue colouring matters of the indophenol group were obtained. If the phenol be replaced by the hydrochloride of an amine and the oxidation be performed by potassium bichromate, indamines are formed, of which the one prepared from aniline can be converted after addition of two more molecules of aniline hydrochloride in acetic acid solution, into a safranine. With metatolylendiamine a difficultly soluble blue colouring matter is formed, which is analogous to Toluylene blue, and is changed into a red colouring matter on boiling its hydrochloric acid solution. Dyestuffs similar to Methylene blue could not be prepared. On oxidation with sulphuretted hydrogen and ferric chloride a red colour was obtained, but no blue.—A. L.

On two β -Bromonaphthalenesulphonic Acids. S. Forsling. Ber. 22, 1400—1403.

THE author obtained these two acids by converting Brömer's β -naphthylaminesulphonic acid and Dahl's β -naphthylaminesulphonic acid into the corresponding diazo-compounds and treating these with fuming hydrobromic acid and cuprous bromide. The concentrated solutions were neutralised with potassium carbonate, when the potassium salts were precipitated.

$\beta_1 = \beta_2$ -Bromonaphthalenesulphonic acid obtained from Brömer's naphthylaminesulphonic acid is very soluble in water. Its salts are, however, very difficultly soluble in it. The potassium, ammonium, and barium salts are described. The bromide of this acid was prepared in the usual way with phosphorus pentabromide. It is easily soluble in benzene and chloroform, with difficulty in petroleum spirit and ether. It forms prisms melting at 110° C. By boiling it with alcoholic ammonia the amide is formed, crystallising in fine long needles, melting at 207° C. On distilling the bromide with the calculated amount of phosphorus pentabromide, dibromonaphthalene is obtained, which, after recrystallisation from alcohol and distillation with steam, was obtained from its solution in ether and chloroform, in colourless square plates, melting at 158° C.

$\beta_1 = \alpha_2$ -bromonaphthalenesulphonic acid was obtained from Dahl's naphthylaminesulphonic acid; its bromide, prepared in the usual way, forms broad needles, melting at 151° C. It was converted into dibromonaphthalene, crystallising in white needles, melting at 75° C. It is identical with the compound obtained by Meldola and Darmstädter, and Wichelhaus, and its constitution is therefore—

—A. L.

Synthesis of Euxanthone. C. Gräbe. Ber. 22, 1405—1406.

ALL attempts at a synthesis of euxanthone have hitherto failed, only isomeric compounds having been obtained. The author has, however, at last succeeded in preparing this body by the action of anhydrous acetic acid on a mixture of β -resorcylic acid and hydroquinone carbonic acid, and by distillation of the product thus obtained. It is in every respect identical with euxanthone; its acetyl compounds have the same properties, and its constitution is therefore—

—A. L.

Studies on Brazilin. C. Schall and C. Dralle. Ber. 22, 1547—1564.

NITRIC acid produces with brazilin tetramethylether first a blood-red, then a brownish-red, and finally an olive-green colouration. An estimation of the molecular weight by Raoult's method proved that the formula $C_{16}H_{10}O(OMe)_4$ is consistent therewith. By the action of bromine, derivatives are obtained, which do not lose any bromine on treatment with dilute ammonia, and which can be crystallised, whilst others losing bromine under the same treatment, crystallise from acetic acid. The analysis of the latter bodies was carried out in the following manner:—

The material was dried over zinc chloride or calcium hydrate until no further loss of weight was observed. The bromine was estimated by treatment with dilute ammonia. Bromine escaping with acetic acid was absorbed in dilute ammonia.

Method of Decomposition.—The weighed substance was decomposed at 40 to 50° C. by standard ammonia, and the excess titrated back with dilute nitric acid, the body to be

analysed itself serving as indicator. It was dried at 192° C. in a stream of dry hydrogen or carbonic acid, the escaping bromine being again absorbed in ammonia, and after deducting its weight from the total loss of weight, the amount of acetic acid was obtained. Finally the total amount of bromine was estimated and a combustion was made.

A.—Derivatives not yielding up Bromine to dilute Ammonia.

Monobromobrazilin was obtained by Buchka and Erk by the action of bromine on tetracetylbraziln and by removing the acetyl groups afterwards. The authors prepared a monobromo product from the tetramethylether. After converting Buchka and Erk's substance into the tetramethylether, its melting point was observed to be 2°—3° C. lower than the one prepared by the authors. A further examination will decide whether the compounds are isomerides or not.

Dibromobrazilin was prepared by the action of 3 mols. of bromine on 1 mol. of brazilin in glacial acetic acid for several days at the ordinary temperature, until the cherry-red solution turns light brown and tribromobrazilin crystallises out. From the mother-liquors dibromobrazilin is obtained in light red plates, which for further purification were recrystallised from water with addition of sulphurous acid. White plates, melting between 170°—180° C. to a ruby-red mass, were obtained. With anhydrous acetic acid a tetracetyl compound is formed, melting after several recrystallisations at 185° C.

Tribromobrazilin.—3 mols. of bromine dissolved in glacial acetic acid are allowed to act for one hour on 1 mol. of brazilin in glacial acetic acid solution. The mixture is poured into cold water and the orange precipitate recrystallised from dilute alcohol with addition of sulphurous acid. It turns brown at 197°—200° C. without melting. Its tri-acetyl compound melts at 195° C. and its tetracetyl compound at 263° C.

B.—Derivatives losing Bromine on treatment with dilute Ammonia.

Tetrabromobrazilin (tribromobrazilinmonobromide) is obtained by boiling 2 or 3 mols. of bromine with 1 mol. of brazilin in glacial acetic acid solution. The yield is from 14 to 15 per cent. It loses one atom of bromine on treatment with dilute ammonia. The complete analysis leaves it undecided whether $C_{16}H_6Br_4O_3 + 1\frac{1}{2} \text{ aq.}$ or $C_{16}H_8Br_4O_3 + 2 \text{ aq.}$ represents the correct formula.

Hexabromobrazilin (tribromobrazilintribromide).—5 grms. of brazilin dissolved in 100 grms. of glacial acetic acid are filtered through glass wool, and a solution of 25 grms. of bromine in 25 grms. of glacial acetic acid is quickly added. The mixture is boiled for half a minute, and on cooling an abundant crystallisation sets in—large brownish-red crystals—losing bromine at 170°—180° C. The substance crystallised from perchloro-ethylene; water or alcohol decomposed it, hydrobromic acid being formed. Its formula is $C_{16}H_6Br_6O_3 + 2 \text{ aq.}$

Octobromobrazilin (tetrabromobrazilintetrabromide) is obtained like the hexa-compound, only the amount of bromine used is doubled. It loses bromine between 130°—140° C. Formula $C_{20}H_{12}Br_8O_3 + 2 \text{ aq.}$

Nonobromobrazilin (tetrabromobrazilinpentabromide) is obtained like the former compound, if the mixture of bromine and brazilin be boiled for 15 minutes instead of one minute. Formula $C_{16}H_5Br_9O_3 + 2 \text{ aq.}$

It is a remarkable fact that on drying the bodies of this series bromine always escapes as hydrobromic acid and not as free bromine.

Among the oxidation products the authors discovered a resorcinol carbonic acid. The authors further studied the properties of brazilin obtained according to Erdmann and Schulze's method and according to Buchka and Erk's method. They prepared the reduction products, the acetyl derivatives produced by acetyl chloride and anhydrous acetic acid.

The brazilin tetramethyl ether, as also the new trimethyl ether demonstrates, along with the acetyl compounds, the phenolic nature of the four brazilin oxygen atoms. Two monobromobrazilins have been in all probability identified, besides the two dibromo-compounds, and a new tribromobrazilin. All these are colourless substances. *But so soon as bromine is introduced in an unstable position, from which it is readily eliminated again, then derivatives possessing tinctorial powers arise.*—A. L.

PATENTS.

Manufacture of Sulpho-Acids, and Colouring Matters therefrom. F. Wirth, Frankfort-on-the-Maine, Germany. From "The Farbenfabrik vormals Brönnner," Frankfort-on-the-Maine, Germany. Eng. Pat. 3724, August 4, 1882. (Second Edition.) 6d.

WHEN naphthol sulphonic acids or their salts are treated with ammonia at a high temperature they are converted into the corresponding naphthylamine sulphonic acids. If β -naphthol be heated with twice its weight of concentrated sulphuric acid of 66° B. for several hours on a water-bath, it is converted into β -naphthol mono-sulphonic acid. 60 kilos. of the neutral or acid ammonium salt of this acid are heated for 24 hours to 150°—180° C., together with 60 kilos. of water and 12 kilos. of calcium hydrate under pressure. The melt is dissolved in hot water, filtered, diluted with about 500 litres of water and made acid. The β -naphthylamine sulphonic acid at once separates, and can be purified by redissolving in an alkali and precipitating with an acid. The acid is slightly soluble in hot water, and almost insoluble in cold, and separates in glistening flakey crystals. Its barium salt crystallises in needles containing 5 molecules of water. The diazo-compound forms colouring matters with the phenols and their derivatives, giving yellows to brownish reds. The combination with resorcinol yields a golden yellow dyestuff, and α -naphthol or its sulphonic acid yields a blood-red dye. The mono- and disulphonic acids of both naphthols can be converted in a similar manner. According to the patent, another β -naphthylamine sulphonic acid is obtained by heating under pressure, at about 180°, 50 kilos. of ammonium β -naphthol sulphonate, 25 kilos. of calcined sodium carbonate of 98°, together with water. The acid formed is almost insoluble in alcohol, but easily soluble in water, whereas the sodium salt is readily soluble in alcohol. The diazo-compound combined with α -naphthol produces a bluish-red dyestuff.—T. A. L.

The Production of New Azo-Colours. M. Hoffmann and A. Weinberg, Mainkur, Germany. Eng. Pat. 9214, July 31, 1885. (Amended, June 15, 1889.) 4d.

THE diazo-compounds of the sulphonic acids of α - and β -naphthylamine combine with α -naphthylamine to form azo-compounds, and these bodies may be again diazotised and recombined with the naphthols or naphthol sulphonic acids in an alkaline solution. The following is the method employed for working the invention:—35 kilos. of sodium α -naphthylamine disulphonate are dissolved in 300 litres of water and 30 kilos. of hydrochloric acid of 21° B., and diazotised by means of 7 kilos. of sodium nitrite dissolved in water. 18 kilos. of α -naphthylamine hydrochloride dissolved in 500 litres of water are then added under constant stirring. A dark violet precipitate separates, and the whole, after standing 12 hours, is treated with 12 kilos. of hydrochloric acid and 7 kilos. of sodium nitrite. The diazo-azo-compound thus formed is added to a solution of 36 kilos. of sodium β -naphthol- α -disulphonate, which is kept alkaline by the addition of 20 kilos. of ammonia of 25 per cent. The colouring matter which is immediately formed is salted out, filter-pressed and dried. Other α - or β -naphthylamine sulphonic acids may be used in place of the α -naphthylamine disulphonic acid mentioned above, but no claim is made to the use of Piria's naphthionic acid or to other amido-mono-sulphonic acids (*i.e.*, those which are not naphthalene derivatives). Other mono- and disulphonic acids of the naphthols, or the naphthols themselves, may be employed in place of

the β -naphthol- α -disulphonic acid mentioned in the second stage of the process described above. The shades given by the various combinations vary from reddish-violet to dark blue.—T. A. L.

Process for the Production of Mixed Azo-Colours. P. Jensen, London. From the "Actiengesellschaft für Anilinfabrikation," Berlin, Germany. Eng. Pat. 15,296, December 12, 1885. (Second Edition.) 6d.

ALREADY described in this Journal, 1886, 595.—T. A. L.

Improvements in the Production of Mixed Azo-Colours. C. A. Martius, Berlin, Germany. Eng. Pat. 2213, February 15, 1886. (Second Edition.) 6d.

THIS patent is an extension of the preceding one (this Journal 1887, 138), and enumerates a number of amines and phenols together with their sulphonic and carboxylic acids with which tetrazo-diphenyl and tetrazo-ditolyl may be combined, producing mixed azo-colours. Examples are also given relating to the employment of benzylic carboxylic acid and benzidine disulphonic acid, together with their homologues, in the formation of colouring matters.—T. A. L.

Improvements in the Production of Green and Bluish-Green Colouring Matters. O. Imray, London. From the "Farbwerke vormals Meister, Lucius und Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 12,796, September 4, 1888. 8d.

THIS invention describes the production of green and bluish-green colouring matters which are to be considered as derivatives of *m*-hydroxydiamidodiphenylmethane—

The leuco-bases of these colouring matters are produced either by condensing *m*-nitrobenzaldehyde with tertiary aromatic amines (Ber. 12, 802), reducing and converting the amines into the corresponding hydroxy-compounds by the action of nitrous acid, or by condensing directly *m*-hydroxybenzaldehyde with tertiary aromatic amines. Colouring matters are produced from these leuco-bases by suitable oxidising agents, and are then converted into sulphonic acids, or the leuco-bases are sulphonated and the leucosulphonic acids subsequently oxidised. The patent also describes the compounds obtained from the methoxy- and ethoxy-derivatives. It is said that the sulphonic acids of the colouring matters when dyed are specially fast to light and washing. The formation of the oxy-compounds from the amido-compounds is illustrated by the following example: 50 parts by weight of *m*-amidotetraethyldiamidodiphenylmethane are dissolved in 35 parts by weight of hydrochloric acid of 33 per cent., and 5,000 parts by weight of water, the whole cooled to 0° and a solution of 8.9 parts of sodium nitrite of 96.5 per cent. slowly added. The whole is then warmed to 60° C. for some time, and finally boiled until nitrogen is no longer evolved. Soda lye is then added till alkaline, when the *m*-hydroxy-leuco-base is precipitated as a crystalline powder which is filtered off, boiled, and dried. In the case of bodies having less basic properties the method is slightly modified. Thirty-five parts by weight of *m*-amidodibenzylidethyldiamidodiphenylmethane—

are dissolved in 30 parts by weight of concentrated sulphuric acid and 4,000 parts of water, cooled to 0° and diazotised with 4.7 parts of sodium nitrite of 96.6 per cent. dissolved in water, the decomposition of the diazo-compound being carried out as described above. These hydroxy-compounds may also be obtained by direct condensation. Twenty

parts of diethylaniline, eight parts of concentrated sulphuric acid, and nine parts of *m*-hydroxybenzaldehyde are heated in a lead-lined boiler fitted with an agitator to 130° C. for 72 hours, the mass made alkaline with soda lye, the unaltered diethylaniline distilled off with steam, and the hydroxy-leuco-base remaining repeatedly boiled with water and dried. The *m*-hydroxy-leuco-bases prepared according to either of the preceding processes may be oxidised as follows into the corresponding colouring matters. Ten parts of *m*-hydroxytetra-ethyldiamidodiphenylmethane are dissolved in 8.8 parts of hydrochloric acid of 30.8 per cent. and the calculated quantity of manganese or lead peroxide suspended in water is added. The colouring matter is precipitated from the filtered solution by the addition of salt and purified by recrystallisation. The hydrochloride of the base thus obtained forms brilliant needles of the colour of cantharides and dyes wool, silk, and tanned cotton a yellowish-green shade. These bodies may be converted into "acid colouring matters" by heating them with six times their weight of fuming sulphuric acid to 50—60° C. until a test dissolves in dilute ammonia with a blue colour. The products are identical with those obtained by sulphonating the hydroxy-leuco-bases and subsequent oxidation as follows: 30 parts of *m*-hydroxytetraethyldiamidodiphenylmethane are dissolved in 150 parts of fuming sulphuric acid containing 10 per cent. SO₃, and the solution allowed to stand until a sample gives a clear solution with dilute ammonia. In the case of some of the compounds it may be necessary to use a stronger sulphuric acid, and to complete the reaction by heating to 70° C. In either case the product of the reaction is poured into water and converted into the calcium salt. To prepare colouring matters from these; 10 parts of the calcium sulphonate from *m*-hydroxytetra-ethyldiamidodiphenylmethane are dissolved in 300 parts of water and oxidised by adding the calculated amounts of dilute sulphuric acid and lead peroxide filtered, and the blue solution of the colouring matter evaporated to dryness. These colouring matters form copper-red powders of a metallic lustre, dissolving easily in water with a blue colour. Excess of a mineral acid turns the aqueous solution green, but the solution is unaffected even when boiled with ammonia or soda, and turns violet only when boiled with soda lye. They dye wool and silk very even bluish-green tints. Colouring matters belonging to the same series are obtained in a manner similar to the processes described above, either by condensing *m*-methoxy- or ethoxybenzaldehyde with tertiary amines or by methylating or ethylating the hydroxy-leuco-bases or the calcium salts of their sulphonic acids mentioned above, and sulphonating and oxidising the compounds so formed in the manner already described. These ethers are said to give better and bluer tints, and are quite as fast as the now substituted hydroxy-derivatives.—T. A. L.

Production of New Colouring Matters. T. R. Shillito, London. From J. R. Griggy, Basle, Switzerland. Eng. Pat. 13,767, September 24, 1888. 6d.

AZOXY and azo-compounds are formed by heating aromatic nitro-compounds with aromatic amines in presence of caustic alkalis. 10 kilos. of *o*-toluidine are heated with 10 kilos. of caustic alkali, and 10 kilos. of nitrobenzene are gradually added. A reddish-brown paste results and the reaction is complete so soon as the mass no longer smells of nitrobenzene. It is then diluted with water, boiled with zinc dust until decolorised, filtered and poured into concentrated hydrochloric acid, boiled and the diamidophenyltolyl formed is precipitated by adding sodium sulphate. The new *p*-diamine formed closely resembles benzidine and tolidine, and is the next higher homologue of benzidine and the next lower one to tolidine. Its sulphate is sparingly soluble. When diazotised it can be combined with amines and phenols similar to benzidine and the colouring matters thus formed when rendered soluble by sulphonation dye unmoderated cotton yellow and red to violet shades.

—T. A. L.

Production of Yellow, Orange, and Brown Colours of Alizarin-like Properties. T. R. Shillito, London. From J. R. Geigy, Basle, Switzerland. Eng. Pat. 13,920, September 27, 1888. 4d.

THESE colouring matters are produced by the action of nitric acid on the bodies obtained by combining diazo-compounds with aromatic hydroxy-acids. 12 kilos. of aniline or a corresponding quantity of toluidine or naphthylamine are dissolved in 36 kilos. of hydrochloric acid and 300 litres of water and diazotised with 9 kilos. of sodium nitrite at 5° C. The solution of the diazo-chloride thus obtained is poured into an alkaline solution of 17 kilos. of salicylic acid or the corresponding quantity of any other oxycarboxylic acid, and the dyestuff precipitated with salt or an acid, filter-pressed and dried. 45 kilos. of the dry compound are dissolved in 135 kilos. of sulphuric acid and a mixture of 20 kilos. of nitric acid and 15 kilos. of sulphuric acid is slowly added. After some time the whole is poured into water, filtered, washed, and brought to the form of a paste.

—T. A. L.

The Production of Dinitrodibenzylbenzidine and Dinitrodibenzyltolidine and Transformation of the same into Diamidodibenzylbenzidine and Diamidodibenzyltolidine respectively. A. Bang, Leeds. From Dahl and Co., Barmen, Germany. Eng. Pat. 3628, March 1, 1889. 6d.

By heating 1 molecule of benzidine with 2 molecules of *p*-nitrobenzylchloride the compound—

is obtained, which on reduction yields the corresponding amido-compound. This by the action of nitrous acid gives tetrazo-compounds, which when combined with amines and phenols or their sulphonic acids yield new colouring matters dyeing cotton yellower shades than those derived from benzidine or tolidine. 18·4 kilos. of benzidine are heated for 3—4 days to 100° C. with 34 kilos. of *p*-nitrobenzylchloride (according to the claim "in water suspension") in an enamelled boiler provided with an agitator and condenser. The dinitrobenzylbenzidine separates as a fine powder, and after filtering off is boiled twice with dilute hydrochloric acid in order to remove unaltered benzidine, after which it is reduced with 35 kilos. of tin and 15 kilos. of hydrochloric acid. The whole is then diluted with water, filtered, and the tin precipitated by means of zinc. The solution containing diamidodibenzylbenzidine and zinc chloride may then be directly diazotised and used for the production of dyestuffs. Diamidodibenzylbenzidine is an amorphous powder scarcely soluble in water but tolerably soluble in alcohol. Its chloride is very easily soluble in water, and the solution is not precipitated by sulphuric acid. Sulphuric acid, however, gives a precipitate when added to an alcoholic solution of the base. The tolidine derivative has similar properties.—T. A. L.

Improvements in the Production of Colouring Matter from Coal-Tar Products. H. D. Kendall, Lowell, Massachusetts, U.S.A. Eng. Pat. 9384, June 6, 1889. 4d.

This invention describes the production of a new fast brown colouring matter called "Essacine," by the action of sodium hydrosulphite on dinitrosoresorcinol or its homologues. 22 lb. of zinc are digested for some time with 17 gallons of sodium bisulphite solution of 35 B., and 1 part by weight of this solution is added to 3 parts by weight of commercial dinitrosoresorcinol containing about 25 per cent. of water. The mixture is constantly agitated when the temperature rises to about 57° C. and the reaction is completed in about one hour. The resulting liquid contains the essacine and may be diluted as desired. Cotton requires to be mordanted, preferably with chromium, the shades produced being, according to the patent, absolutely fast to soap, light, and acids. It can also be dyed together with alizarin and when mixed with Coeruleine, Viridine, &c. to produce different shades, gives colours which are said to be faster than when the Essacine is omitted.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Black Spots on Cellulose. W. Herzberg. Mith. Königl. techn. Versuchs. 1889, 62—64.

A SAMPLE of cellulose prepared by the Ritter-Kellner process was disfigured by numerous black spots varying in size from that of a pin head to that of a medium-sized pea.

The appearance was quite different from that occurring in straw cellulose which has been stored in damp places. Microscopical examination demonstrated the existence of a fungoid growth, twining round the cellulose fibres as ivy does round a tree. The brown colour of its mycelium caused the patches of it to be visible to the naked eye as dark specks. It was thought that the germs had been derived from the river water used in the manufacture, spring water not being available, but it is more likely that they came from the air, finding a good soil on the moist cellulose.

Calcium sulphite was recognised on the spots by Frank's method with iodine solution (*Papier-Zeitung*, 1888, 10), and if this be viewed as the cause of the growth the obvious remedy is to avoid its presence in the finished product; on the other hand the acid juices of the growth itself will tend to liberate sulphurous acid from the calcium sulphite and arrest its development. Thorough drying is an effective preventative, and where this is impracticable zinc chloride in the proportion of 1 litre at 40° B. to 100 litres of water proves a reliable antiseptic, 40 kilos. of such a solution sufficing for 100,000 kilos. of cellulose. So small a quantity interferes with neither the sizing nor the colouring processes.

The author recapitulates a few facts bearing on this subject that have appeared from time to time in the "*Papier-Zeitung*."

It was observed that a paper made from pure rags and highly sized with rosin developed a fungoid growth when kept in a warm damp place; there is no direct evidence to show whether the germs are derived from the water or air. Adequate nutriment for the mould is supplied by size of animal origin, and even when rosin is used the accompanying starch may prove sufficient.—B. B.

PATENTS.

Improvements in the Treatment of Flax and other Fibrous Plants for obtaining the Fibre therefrom for Spinning and other Manufacturing Purposes. L. Dekien, Courtrai, Belgium. Eng. Pat. 11,397, August 7, 1888. 6d.

By this invention the costly and troublesome process of retting is entirely done away with and the flax as cut is taken direct from the field to the scutching machine.

—E. J. B.

An Improved Method or Process of Freeing Rhea and other Vegetable Fibres from Cementitious Matter, and Apparatus therefor. G. F. Redfern, London. From E. F. Spence, Rotterdam, Holland. Eng. Pat. 11,973, August 18, 1888. 8d.

THE fibre to be treated is made into a coarse tissue with strong yarn, the latter forming the warp and the former the woof. Two boilers are then filled with this tissue. The boilers are connected together with suitable pipes, so that the liquid used for treating the fibre may be transferred from one to the other at will. In its passage from one boiler to another the liquid passes through a filter-press. A great saving in chemicals is claimed.—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Substantive Cotton-Dyes. E. Noelting. Chem. Zeit. 13, 777—778.

ROSENSTIEHL and Noelting have recently discovered that dimeta-amido-derivatives of azoxy-compounds, such as azoxyaniline (dimeta-amidoaz-oxylbenzene), the two azoxytoluidines, and az-oxymetaxylidine, are bases from which a new class of substantive cotton-dyes may be obtained. The most important of these new dyes is one known as St. Denis red, which is produced by acting with α -naphthol- α -sulphonic acid on diazotised *o*-toluidine. It is distinguished by its fastness and perfect resistance to acids. It is not fixed on the fibre from an alkaline bath so easily as benzopurpurin and Congo-red, but full shades can be produced by modifying the ordinary conditions of dyeing. Rosenstiehl gives the following method of dyeing 10 kilos. of cotton, either yarn or cloth: 200 grms. of St. Denis red are dissolved, by the aid of heat, in 6 litres of caustic soda of 7° B, this solution being poured into a warm bath containing 200 litres of water, 48 kilos. of common salt, and 5 litres of caustic soda of 40° B. The bath is heated to 85°, the cotton entered, the heat raised to 90°—95° and kept at this temperature for half-an-hour. At the end of this time the goods are taken out, squeezed or wrung, and passed for 5—10 minutes into a 1 per cent. solution of sulphuric or hydrochloric acid, then well rinsed and dried. The dye-bath is not exhausted and should be preserved, being made up for use again by the addition of 165 grms. of dyestuff, dissolved in 5·7 litres of caustic soda of 7° B, and 0·5 litre of caustic soda of 40° B. for each 10 kilos. of cotton. A very deep red is obtained by taking, for the same weight of cotton, 300 grms. of dyestuff and 9 litres of caustic soda of 7° B. for the first bath, and 250 grms. of dyestuff with 8½ litres of caustic soda for subsequent baths. The dye-bath should be heated with closed steam and the volume of water evaporated must be replaced. Excellent results are obtained by strictly following the directions.

H. Koechlin recommends, more particularly for piece dyeing, a method based on the fact that the alumina-zinc-magnesia lake of St. Denis red is exceedingly bright and fast to soap. The cloth is mordanted by a passage through a solution containing, per litre of water, either 0·5 litre of acetate of magnesia of 30° B. and 0·5 litre of acetate of alumina, or 150 grms. of sulphate of magnesia and 50 grms. of alum. It is then dried and passed for two minutes into a bath, consisting of 50 grms. of sulphate of zinc and 100 cc. of caustic soda of 38° B. per litre of water, after which the pieces are rinsed and dyed per metre of cloth with 2—3 grms. of dyestuff dissolved in 2½ litres of water along with 400—500 grms. of common salt and 5 grms. of lime, the temperature of the bath being raised to 80° in the course of an hour, maintained at this temperature half an hour, and the cloth then rinsed and dried.

C. Schoen communicates a simpler and quicker method: 35 grms. of dyestuff are dissolved in each litre of water, with the addition of 20 grms. of aluminat of soda of 15° B. and 5 grms. of caustic soda of 38° B. To each litre of this solution there may further be added 100 cc. of a solution prepared by dissolving 100 grms. of sulphate of magnesia per litre of water and adding 200 grms. of caustic soda of 38° B. The pieces are padded with this solution, left rolled up for an hour, then passed through a bath of 50 grms. of alum per litre of water, rolled up again for two hours, and finally washed and dried. Ammonium chloride or sodium bisulphite may be used instead of alum in the fixing-bath.

Discharge effects may be obtained on the new red by means of stannous salts as with benzopurpurin, &c.—E. B.

Dyeing with Resorcinol Green and Cobalt Nitrate.

E. Kopp. Bull. Soc. Ind. de Rouen, 1889, 17, 139.

THE material is printed with a mixture of cobalt nitrate and sodium acetate in the usual manner, passed through a bath of sodium aluminate or sodium silicate, and then dyed with

resorcinol green (dinitrosoresorcinol), calcium chloride being subsequently added to the bath. Sodium aluminate gives better results than silicate. Dinitrosoresorcinol combines so readily with cobalt oxide that the brown colour, due to the union of these two substances, is produced almost instantaneously.—E. E. B.

PATENTS.

An Improved Process or Method of Dyeing or Painting on Fabrics and other Materials, and Apparatus employed therefor. C. and H. Dratz, Brussels, Belgium. Eng. Pat. 9044, June 20, 1888. 11d.

THE materials, consisting of textile materials spun, woven, or in fibre, wood, leather, paper, &c., are impregnated with mordants or colours in the form of a spray. Patterns in several colours may be obtained by protecting portions of the material by means of stencil plates or open-work patterns. The mechanical arrangements are described with the aid of drawings.—E. B.

Improvements in Bleaching, Dyeing, &c. J. C. Mewburn. From La Société Leblois, Piceni, et Cie., Paris, France. Eng. Pat. 11,452, August 8, 1888. 8d.

THIS invention has reference to Eng. Pat. 11,637 of 1885 (this Journal, 1886, 533). For bleaching or dyeing without deteriorating or felting the materials, two vessels are employed, one being a vessel which can be hermetically sealed, and in which a vacuum can be produced, the other a vessel in which a wheel revolves. In the vacuum chamber, which is preferably employed for steeping operations, there are placed at the top and bottom perforated pipes for the inlet and discharge of air and liquids, also a rack mounted on wheels, and divided into compartments for the reception of small portable boxes made of perforated sheet metal or formed of hollow rods with jointed sides, which serve to hold the materials to be operated upon. When working, a vacuum is created in the vessel by the upper pipes, and the steeping liquor, which has been prepared in an adjoining vessel, is drawn into the vessel by the pipes at the bottom until the boxes are entirely submerged. The formation of a vacuum is repeated several times, alternating with admissions of air through the lower pipes, which produce an agitation of the bath. The steeping-bath is then emptied, the vessel opened, and the boxes transferred to the compartments of the revolving wheel for the final operations of bleaching or dyeing. The wheel having been charged, the bleaching or dyeing is effected by turning the wheel alternately to the right and left whilst submerged in the bath. The steeping is best done at a temperature of 50 to 30° C. for materials which have to be bleached, and 10° to 80° C. for materials which have to be dyed. In steeping for bleaching, either water alone is used or an alkaline solution, or preferably a solution containing three-tenths per cent. of neutral hypochlorite of soda, made by double decomposition between caustic soda and bleaching powder solution, and known as "chlorogene." The steeping-bath preceding the dyeing may be formed of water or alkaline solution, but preferably contains a little dye, which can serve as a ground for the shade to be afterwards obtained. For certain dyes the preparatory steeping of vegetable fibres may be omitted.

Materials composed of animal fibres, which have already been scoured, are placed in the wheel and bleached or dyed at once, instead of undergoing a preliminary steeping.

—E. B.

Improvements in Dyeing Aniline Black. E. and G. E. Sutcliffe, Halifax. Eng. Pat. 11,806, August 16, 1888. 6d.

IN the dyeing of aniline black there is a formation of precipitate in the bath, not only representing a loss of material, but in the process of dyeing wherein the liquors are caused to circulate, interfering with the dyeing by preventing the flow of liquor. In the method given below, the whole of the dye-liquor employed is absorbed, and relatively less acid and oxidising agent require to be used.

The goods are saturated with a liquor composed of materials in the following proportion :—

- 120 gallons of a 5 per cent. solution of aniline hydrochloride,
- 20 gallons of a 5 per cent. solution of potassium chlorate,
- 15 gallons of a 6 per cent. solution of ferrous sulphate,
- 4 gallons of commercial hydrochloric acid.

The saturated goods are allowed to rest in a warm room or suitable ageing place for about 24 hours, and then treated according to the stage of development of the black. If the goods at the end of this time are of a green colour they are treated with an oxidising agent, such as bichromate of potassium; if, however, the black has completely developed, they are simply rinsed. Other oxidising agents may be used, such as potassium or sodium bichromate, alkaline chlorates or hypochlorites, bleaching liquor, or any agent ordinarily used for, or which will produce, the desired effect.
—E. B.

Improvements in Apparatus for Dyeing, Scouring, &c. W. Brown, Selkirk. Eng. Pat. 12,485, August 30, 1888. 6d.

A VESSEL, serving for the reception of the material to be operated upon, is fitted inside a double-jacketed vessel of similar shape. The inner shell is perforated at the bottom and round the sides near the top. When the apparatus is filled with water, &c. the application of heat causes the liquor to flow through the upper perforations and out at the bottom of the inner shell. In this way the felting of the fibres is avoided. Dyewoods, from which the colouring matter has to be extracted, are, by preference, placed below the inner shell. A drawing is given.—E. B.

Improvement in Blueing Preparations for Laundry and Similar Purposes. H. E. Hounsell, London. From G. A. Conant, Acton, Mass., U.S.A. Eng. Pat. 12,670, September 3, 1888. 6d.

SHEETS of Manila paper are dipped into a filtered solution of Prussian blue in oxalic acid and dried. Sugar is added to the solution to cause the blue to adhere to the dried paper.—E. B.

An Improved Blue for Laundry Purposes in the Form of Crystals. G. R. B. Kempton, West Ham. Eng. Pat. 5380, March 29, 1889. 4d.

A BLUE aniline or other dye is dissolved in water, and potash alum and common salt mixed with the solution, which is then concentrated and set aside for crystallisation. Blue crystals are thus obtained. It is claimed, as an improvement, for this preparation, that it has an attraction for all fibres, inasmuch as the potash alum acts as a mordant for the same; goods are more readily blueed, and an even colour is produced, as the crystals are perfectly soluble.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Boracite from Douglasshall. C. Oehsenius. *Nen. Jahrb. f. Mineralogie*, 1889, 1, 271.

CRYSTALS of boracite and iron boracite have been obtained from carnallite at Douglasshall. The more recent layers of carnallite are richer than the older, but the yield is very variable. Pseudomorphs of boracite have been found there, and also in blondeite, a mineral similar to glaserite in composition.—E. E. B.

Discoveries at the Saline Deposits at Douglasshall. C. Oehsenius. *Nen. Jahrb. f. Mineralogie*, 1889, 1, 272.

A. NAUFERT has found the following minerals in carnallite at Douglasshall:—Crystallised iron-boracite, pyrites, red rock crystal, dark specular iron ore, Löwigite (?) sulphur, Bischofite, and tachyhydrite.

The so-called "Hartsalze" have also been found associated both with carnallite and kieserite, containing 46 to 58 per cent. magnesium sulphate and about 23 per cent. potassium chloride.

In the kainite is found blædite, krugite (associated with polyhalite), Reichardite, and blue rock salt.

Another interesting find is a crystallised sulphate of sodium and potassium (glaserite?), which occurs with astrakanite, and contains 59 to 66 per cent. potassium sulphate and 18 to 22 per cent. sodium sulphate.—E. E. B.

Action of Magnesium Chloride on Lead Oxide. A. Voigt. *Chem. Zeit.* 13, 695.

ANDRÉ has previously described the formation of oxychloride of lead by the action of chlorides of calcium, strontium, and barium on lead plaster, but considered that magnesium chloride had no action. The author, however, finds that upon boiling lead plaster with a concentrated solution of magnesium chloride, filtering, and adding cold water to the filtrate, a precipitate is obtained, which when dried at 100° C. has the formula $3\text{PbO} \cdot \text{PbCl}_2 \cdot \text{H}_2\text{O}$. Lead carbonate is also soluble in magnesium sodium, though not to the same extent as lead oxide.—E. E. B.

The Removal of Arsenic from Chamber-Acid. Le Roy W. McCay. *Chem. Zeit.* 13, 725—726.

THE author proposes to remove arsenic from chamber-acid by treating the acid with hydrogen sulphide, whilst it is contained in air-tight leaden cylinders, which are heated by a steam-coil or jacket. The cylinders should also be provided with stirring-gear, to cause the precipitated arsenic pentasulphide to collect together and settle.—E. B.

The Action of Acids, especially of Sulphuric and Hydrochloric Acids, upon Sodium Thiosulphate. W. Vaubel. *Ber.* 22, 1686—1694.

It is generally assumed that sodium thiosulphate is decomposed by acids with the liberation of sulphur dioxide, the separation of sulphur and the formation of water and of the sodium salt of the acid employed. This is the case with the following acids: formic, acetic, succinic, citric, hydrochloric, hydrobromic, hydriodic, hydrofluoric, nitric, sulphurous, dithionic, dilute sulphuric, and dilute phosphoric. Other acids, however, give rise to the formation of sulphuretted hydrogen. Of these, concentrated sulphuric acid produces the largest proportion of sulphuretted hydrogen, and the quantity increases with the strength of the acid. Aqueous hydrocyanic acid gives, when heated with the solid thiosulphate, a considerable evolution of sulphuretted hydrogen; butyric, oxalic, and tartaric acids cause a slight production of sulphuretted hydrogen, as do hydrofluosilic acid and carbon dioxide. In most of these cases the application of heat favours the formation of the hydrogen sulphide. The author has specially examined the action of sulphuric and of hydrochloric acids.

1.—*Decomposition of Sodium Thiosulphate by Sulphuric Acid.*

The decomposition as represented by the following equation is not complete :—

The degree of decomposition varies with the strength of the acid, and in order to obtain concordant results when employing acids of the same strength it is necessary to use 8—10 times as much acid as is required according to the equation. In carrying out the experiments, 10 grms. of the solid thiosulphate were decomposed by the acid in a suitable flask. The decomposition, which was conducted in the cold, was allowed to extend over two hours, when the sulphur dioxide (together with the sulphuretted hydrogen) was determined by absorption with water and titration with iodine. The separated sulphur was collected and weighed, and the total amount of sulphuric acid remaining at the end of the experiment determined volumetrically. The

following table contains the results of the experiments, the percentages being taken on the quantities which should have resulted according to the equation—

Per Cent. of H_2SO_4 in Acid employed.	SO_2 obtained.	S obtained.	Free H_2SO_4 .
	Per Cent.	Per Cent.	Per Cent.
20	73.9	100.11	98.17
30	82.6	92.21	98.87
40	..	96.71	105.97
50	85.7	101.34	136.01
60	85.3	102.99	197.15
70	84.8	109.60	110.50
80	85.2	95.86	109.60
90	92.0	99.40	109.20
100	45.4	9.15	119.69

In the two last cases sulphuretted hydrogen was formed, which was determined with the sulphur dioxide. In no case does the quantity of sulphur dioxide reach the required amount, whilst that of sulphur exceeds the 100 in four cases, and a steady rise in the percentage of sulphuric acid occurs as the strength of the acid employed in the decomposition increases. It is concluded from this that the thiosulphuric acid at the moment of its liberation decomposes thus :—

and then that these products mutually react as follows :—

11.—Decomposition of Sodium Thiosulphate by Hydrochloric Acid.

The decomposition in this case supports the above idea as to the decomposition products of thiosulphuric acid. Using 10 times the theoretical amount of 20 per cent. hydrochloric acid under similar conditions to those described above, the quantity of sulphur dioxide was always found to be less, that of sulphur more than should be formed according to theory, and further the production of sulphuric acid was observed in every case.

The action of silver oxide on sodium thiosulphate also confirms the author's view as to the decomposition of thiosulphuric acid. Geuther (Ann. Chem. Pharm. 1884, 226, 232) has shown that silver sulphide and sodium sulphate result, and this decomposition is shown to be a complete one, the total sulphur being in the form of sulphide and sulphate, whilst no sulphurous acid is formed. The following equation represents this decomposition :—

—C. A. K.

Sulphites and Thiosulphates. A. Schwicker. Ber. 22, 1728—1737.

A SERIES of experiments are described with the view of proving the asymmetric nature of the sulphites and thiosulphates of the alkali metals.

Regarding sulphurous acid as H_2SO_2 , OH two isomeric sodium potassium sulphites $\text{K} \cdot \text{SO}_2 \cdot \text{ONa}$, and $\text{Na} \cdot \text{SO}_2 \cdot \text{OK}$ are possible. By the addition of the requisite quantity of sodium carbonate to a concentrated solution of acid potassium sulphite hard yellowish crystals of the double salt containing two molecules of water of crystallisation result, No. I. Potassium carbonate and acid sodium sulphite give indistinct crystals also of a yellowish colour which contain one molecule of water of crystallisation, No. II.

Heated with ethyl iodide in a sealed tube to 140° , the former gives the double salt $4 \text{C}_2\text{H}_5 \cdot \text{SO}_2 \cdot \text{OK} + \text{NaI}$, the latter $4 \text{C}_2\text{H}_5 \cdot \text{SO}_2 \cdot \text{ONa} + \text{KI}$.

The analytical data agree fairly well with the above composition of these double salts, and it is suggested by the author that in both cases the metal attached to the sulphur has been replaced by the alkyl group according to the equations—

Sodium potassium sulphites corresponding to the above have also been prepared by Röhrig (J. Prakt. Chem. 37, 250; this Journal, 1888, 322).

Neither acid sodium nor potassium sulphite yield double salts with the corresponding normal sulphites. Either of the above sodium potassium sulphites give a double salt with acid sodium sulphite having the composition $\text{HKNa}_2(\text{SO}_3)_2 + 4 \text{H}_2\text{O}$. This salt is also obtained by treating acid sodium sulphite with potassium carbonate, or by evaporating a mixture of the acid sodium and potassium sulphites, or finally by passing sulphur dioxide into a solution of either of the sodium potassium sulphites. In all these cases the products appear to be identical.

The double salt is stable, and only evolves sulphur dioxide on long standing; it is readily soluble in water, and the concentrated solution combines with acetone, pointing to the presence of an acid sulphite. The double salts $\text{HNaK}_2(\text{SO}_3)_2 + 3 \text{H}_2\text{O}$, and $\text{H(NH}_4\text{)Na}_2(\text{SO}_3)_2 + 4 \text{H}_2\text{O}$ are also described; they resemble the above in properties, and the latter is obtained by passing ammonia gas into a concentrated solution of acid sodium sulphite.

The sodium potassium sulphites can be converted into the corresponding thiosulphates by treatment with a freshly prepared concentrated solution of ammonium pentasulphide, and then boiling off the excess of ammonia. Salt No. I. yields tabular crystals, having the formula $\text{NaKS}_2\text{O}_3 + 2 \text{H}_2\text{O}$; these are readily soluble in water, melt at 57°C ., and have a specific gravity of 1.970 at 15° . Salt No. II. yields a similar thiosulphate also containing two molecules of water of crystallisation, but they melt at 62° , and have a specific gravity of 1.930 at 15° . When heated with ethyl bromide for some hours the former is converted into potassium ethyl thiosulphate, the latter into sodium ethyl thiosulphate, both crystalline compounds; the sodium and the potassium have been respectively replaced by the ethyl group, and since the ethyl group would in all probability attach itself to the sulphur atom united directly to the metal, the constitutional formulae for the two thiosulphates would be—

No. I.

No. II.

Both these thiosulphates treated with iodine are converted into potassium tetrathionate; salt No. II. should give sodium tetrathionate, but potassium iodide is formed in the reaction which decomposes the sodium tetrathionate with formation of the potassium salt as was proved by direct experiment. For a similar reason both the thiosulphates yield a potassium silver thiosulphate having the formula $\text{KAgS}_2\text{O}_3 + \text{NH}_3$ when treated with an ammoniacal solution of silver nitrate. This compound loses its ammonia at 100° , and leaves a brown powder; the aqueous solution readily decomposes with separation of silver sulphide. Sodium silver thiosulphate ($\text{NaAgS}_2\text{O}_3 + \text{H}_2\text{O}$) previously obtained by Lenz (Ann. Chem. Pharm. 40, 91) is also described.

The author draws the conclusions that the above facts point to the asymmetric constitution of the sulphites and thiosulphates.—C. A. K.

Nitrous Vitriol, and its Purification for the Manufacture of Aerated Waters. Pharm. Conference, Newcastle-on-Tyne. Pharm. J. 1889, 204.

At the *Pharmaceutical Conference* just recently held at Newcastle-on-Tyne, J. Pattinson read a paper upon the above subject. He had observed that when nitrous vitriol is employed to generate carbonic acid for charging ginger ale, the beverage obtained was more or less turbid. J. Pattinson found that the amount of nitrous compounds required to cause this turbidity was almost infinitesimal, 0.026 per cent. of N_2O , in the objectionable vitriol being sufficient to give rise to turbidity, whilst with the pure article a perfectly clear ginger ale resulted. Naylor pointed out that the pungency of the ginger essence, as well as that of the capsicin, were destroyed by the nitrous compound. T. H. Williams had also experienced the same troubles, but he added that, though ginger essence lost pungency and flavour, he had observed a similar effect on all kinds of aerated waters, and he found it was due to the nitrous fumes carried over in the carbonic acid gas. He had remedied this defect by passing the carbonic acid gas through a scrubber down which an alkaline solution of permanganate of potassium was allowed to trickle. The effect was all that could be desired. Pattinson proposed as a remedy to heat the vitriol with a little ammonium sulphate, which entirely destroys nitrous compounds. The presence or absence of these compounds can then be ascertained by adding a drop or two of permanganate to 20 cc. of the oil of vitriol, to which water is then added. If free from nitrous compounds, the pink colour is retained. The diphenylamine reaction might also be applied, and is still more delicate.—W. S.

PATENTS.

Improvements in obtaining Chlorine from Hydrochloric Acid or Chlorides, and in Regenerating Peroxide of Manganese which is used in the Process. A. Campbell, London, and W. Boyd, Glasgow. Eng. Pat. 10,187, July 13, 1888. 61.

MANGANESE chloride (obtained by acting upon manganese peroxide with hydrochloric acid for the production of chlorine) is heated with sulphuric acid and a further quantity of manganese peroxide. The whole, or nearly the whole, of the chlorine is obtained in the free state, sulphate of manganese being formed at the same time. This latter is dissolved in water and treated with carbonate of ammonia. The precipitated carbonate of manganese is separated, and converted into peroxide by any suitable means; the sulphate of ammonia is recovered by concentration and fishing in the usual way. Three modifications of the process are described.—A. R. D.

Improvements in the Manufacture of Permanganates and Chlorates. G. H. Bolton, J. R. Wyde, and H. Auer, Widnes. Eng. Pat. 10,193, July 13, 1888. 6d.

A SOLUTION of mangenate of soda which has been treated with chlorine, as described in Eng. Pat. 8217 of 1887 (this Journal, 1888, 437), and which contains sodium chloride and chlorate, as well as permanganate, is evaporated to about 90° Tw. During this process about two-thirds of the chloride present separates out and is removed by fishing. Potassium chloride is now added, in quantity rather less than sufficient to convert all the sodium permanganate into the potassium salt, and the solution, standing at about 80° Tw., is allowed to cool. The bulk of the permanganate crystallises out, and a second crop of crystals may be obtained by a further concentration to 130° with occasional removal of sodium chloride by fishing. The strong mother-liquor is freed from the remaining small quantity of manganese in solution by treatment with sulphuretted hydrogen or a soluble sulphide, after which it contains only the chlorate and chloride of sodium in about equivalent proportions. Further concentration to 100°—120° Tw., and fishing, removes a portion of the sodium chloride; the settled

liquor deposits on cooling chlorate of soda of great purity. If chlorate of potash be required, the necessary amount of potassium chloride should be previously added.—A. R. D.

Improvements in the Treatment of Sulphuretted Hydrogen to obtain Sulphur, and in Apparatus employed therein. J. Hargreaves, Ditton. Eng. Pat. 10,322, July 17, 1888. 6d.

SULPHURETTED HYDROGEN is intimately mixed with a volume of air just sufficient for the combustion of its hydrogen, and then caused to pass through a number of perforated blocks preferably built up of spiral-shaped pieces of earthenware or metal similar to those employed in the regenerator of the Hargreaves thermo-motor. These blocks are preferably placed one behind the other in a closed chamber, the intervening spaces being occupied by gauze-like material, to prevent the return of the flame. This end is better attained by making one of the blocks of metal, and keeping it cool by circulation of water. After passing the blocks the gaseous mixture is injected at a tangent into a tubular-shaped combustion chamber, made so long as to avoid sudden cooling before complete decomposition of the sulphuretted hydrogen. In order to recover as free sulphur any sulphur oxidised during the decomposition, the residual gases are passed through the solution of some suitable chloride, or they are scrubbed in any ordinary method for the recovery of the sulphur acids, and these, when concentrated, are injected into the hot end of the combustion chamber.—A. R. D.

Improvements in the Manufacture of Nitrate of Ammonia. C. N. Hake, London. Eng. Pat. 11,731, August 14, 1888. 4d.

It is proposed to produce solid nitrate of ammonium by bringing together nitric acid vapour and ammonia gas in a suitable mixing chamber, or by spraying liquid nitric acid into a chamber into which a current of ammonia gas is caused to flow. In the first case the nitrate is obtained as a fine powder; in the second as a supersaturated solution, solidifying on cooling. Care must be taken that the heat of combination be not allowed to raise the temperature in the mixing chamber above 120° C.—A. R. D.

Improvements in the Manufacture of Chloride of Aluminium with other Chlorides. W. White, Cheshunt. Eng. Pat. 12,543, August 31, 1888. 4d.

SODA or potash alum is dried, powdered, and intimately mixed with enough sodium or potassium chloride to convert the aluminium of the alum into aluminium chloride and to form with the same a double chloride. When the mixture is fused at a red heat the double chloride sublimes, leaving potassium or sodium sulphate behind in the retort or crucible.—A. R. D.

Improvements in the Manufacture of Soda Alum. E. Augé, Montpellier, France. Eng. Pat. 6443, April 15, 1889. 4d.

SOLUTIONS of sulphate of soda and sulphate of alumina when mixed together in the proper proportions cannot well be evaporated in the ordinary way to the density necessary for crystallisation without employing a temperature of at least 70°—80° C., and the soda alum solution when heated to this degree is rendered incapable of crystallising. The inventor obviates this difficulty by conducting the evaporation under reduced pressure, and obtains the required specific gravity (1.38 to 1.46) at a temperature of about 45° C.—in no case exceeding 60° C.—A. R. D.

Improvements in the Process of Manufacturing Caustic Soda or Caustic Potash. W. P. Thompson, Liverpool. From J. A. Bradburn, Syracuse, U.S.A. Eng. Pat. 6710, April 20, 1889. 4d.

To two molecules of sodium chloride are added four of nitric acid and one of peroxide of manganese. The mixture is heated by steam in a stoneware retort, the following reaction taking place:—

The chlorine thus produced is used in the ordinary way for making bleaching powder. The manganese in the residual liquors is precipitated with caustic soda, and then oxidised by a current of air, which renders it again available for use in the first stage of the process. The nitrate of soda left in solution is recovered by evaporation, mixed with ferric oxide, and heated in a current of air. The mixture of nitrous gases is passed over some oxidising manganese compound and treated for the recovery of the nitric acid. The mass remaining in the furnace yields on lixiviation a solution of caustic soda. The remaining ferric oxide can be used over again. Instead of manganese peroxide a manganate or permanganate may be used in the first operation. The process is equally applicable for the production of caustic potash.—A. R. D.

A New or Improved Process for making Metallic Sulphates in Solution. H. E. Newton, London. From L. O'Brien, Sydney, New South Wales. Eng. Pat. 8045, May 14, 1889. 4d.

The ores or minerals to be dissolved are placed in water in a vat provided at the bottom with a chamber into which are pumped under pressure sulphurous acid and steam. The mingled gases escape from this chamber by slits in its sides, and bubbling up through the contents of the vat, effect the "sulphating" of the ore therein. The boiling temperature requisite for speedy solution is maintained by the steam with which the sulphurous acid gas is mixed. In certain cases the action may be accelerated by the help of an oxidising agent such as nitrous acid or oxide of manganese.—A. R. D.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

The Solubility of Glass Bottles. R. Reynolds. Pharm. Conference, Newcastle-on-Tyne.

REUTER (*Pharm. J.*, Aug. 31, 1889) showed that chloral hydrate (cryst.) which had been kept some time in a blue glass bottle, acquired a blue tint, the colour being proved to be due to pigment derived from the glass of the bottle. Glass is known to be affected by alkaline solutions, and the glass windows of stables even become gradually attacked by the ammoniacal emanations from decomposed and decomposing urine. It was also pointed out that glass that has lain in mud becomes disintegrated, and hydrocyanic acid kept in white flint glass bottles becomes decomposed, owing apparently to the action of the glass. As a matter of personal experience, Reynolds mentioned that a solution of 1 in 10,000 of hydrochloric acid in water, which when freshly made gave a distinct reaction with congo-paper, failed to do so after being kept a day in a flint glass bottle. This result he was inclined to refer to the chemical interference of the bottle with its contents. The observation was confirmed in a similar one by Thresh, who, in testing the action of acid fumes in the

smoke of a neighbourhood on vegetation, found that whilst the rain collected directly on litmus papers was acid, that collected first in glass bottles showed either a neutral or an alkaline reaction. He tried all kinds of bottles, with a similar result. Some of the rain water was then collected in platinum dishes, and the water collected in bottles gave him 5 grains per gallon more solid residue than that collected directly in platinum. This residue was chiefly silica, pointing to the fact that a decomposition of the silicates of soda or lime, or both, had probably taken place.

Linford stated that hydrochloric acid acted very considerably on bottles, but sulphuric acid did not. The action of hydrochloric acid, however, soon ceased, and the bottle was no longer acted upon. Martindale had observed that *osmic acid* very much affects white glass bottles. The English-made bottles were chiefly affected. Nearly all foreign glass bottles stood the action of the acid exceedingly well. Where the grinding of the stopper occurred the action was only slightly noticeable. This result was considered to be due to the fact that English bottle glass contains more lead than the foreign glass. Bottles made of glass containing no lead would be found to stand the osmic acid very well. Weddell confirmed the statement that English bottle glass contains a considerable percentage of lead, whilst the French and German glasses are free from that metal.—W. S.

Mexican Pottery Glaze.

IN the current number of *Harper's Monthly Magazine* is an interesting announcement of a discovery of a band of Mexican Indians who manufacture a pottery glaze, which, in an introduction to the article, the expert in potteries, W. C. Prime, compares to the wondrous old glazes of Gubbio and the Florentine potters. "The fact stands," he says, "that to-day in San Felipe unskilled Indians are producing and selling for daily use in Mexico wares decorated with a lustre incomparably finer than any metallic lustre produced in Europe, and which, if potters can by experiment learn so to use it that different colours can be produced as desired, will practically restore to modern uses the lost Saracen and Italian lustres."

As much of the secret as the San Felipe Indians possessed is out, for at some risk Miss Y. H. Addis has penetrated to where the pottery was made, and has secured the entire process of firing, &c., adopted by the makers of these beautiful wares. She thus describes it: "The vessels once moulded, are fired, and when thoroughly cold are glazed with a mixture of (1) oxide of lead; (2) broken glass, which they buy from the refuse of shops; (3) 'peacock copper'; and (4) a very fine sand found near San Felipe. It was impossible to obtain even an approximately accurate idea of the proportions employed, because the potters have so long worked by the rule of thumb that they are really incapable of describing the quantities. Therefore, this point would have to be determined by examination during their practical working. After application of the glaze comes a second firing—the one in progress at the time of the visit. The ware emerged from the kiln at this stage dull and clouded, of a thick muddy brown or greenish colour. As rapidly as possible the potter buried the pieces in a great heap of stable manure, and after from one to hours they were disinterred, transformed by the ammoniacal fumes to a lustrous brilliance, with the shifting, varying hues that gleam on the breast of a peacock. The secret, if secret there be, seems to lie in two of the elements of the glaze, in combination with the ammonia treatment, for I am sceptical as to the potter's assertion that the effect is due to peculiar properties in the clay of San Felipe."—*Engineering and Mining Journal*.

PATENT.

Improvements in the Manufacture of Red Glass. H. J. Haddon, London. From the Josephine Glass Works of Count Schaffgotsch, Schreiberhan, Germany. Eng. Pat. 11,016, July 30, 1888. 6d.

The following mixture is prepared and melted in an open pot:—

	Parts.
Pine sand	2,000
Minium	400
Potashes	600
Lime	100
Phosphate of lime	20
Tartar (bitartrate of potash)	20
Borax	20
Red oxide of copper	9
Binoxide of tin (putty powder)	13

This gives at one melting a homogeneous glass of a transparent red colour, from which articles may be made direct without flashing, and without the necessity for a second heating to bring out the colour.—A. R. D.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Natural Cements. A. Cluss. Eng. and Min. J. 47, 516.

LIMESTONE, with intimate fine-grained admixtures of silica, alumina, magnesia, &c., in quantities of 35 to 60 per cent., are called cement stones. The high percentage of silicates causes a separation of the alumina from the silica during calcination at a red heat just sufficient to expel the carbonic acid. Oxides of iron and chloride of potash are generally present in small quantities. The burned lumps must be pulverised before they will combine with water, when they form hydrated silicate of lime, while the alumina remains practically inert. These cements set quickly, but harden slowly under water without shrinking, and attain gradually great strength, with well developed adhesive force. They bear doses of sand of double their own volume or over. From 30 to 40 per cent. of water must be added. Many American cements of this class contain large percentages of carbonate of magnesia. The tests of strength, in pure state as well as mixed with sand, compare well with the cements which do not contain these combinations. De Smeth found for Virginia cements in the pure state, after 30 days' exposure, 170—250 pounds tensile strength per square inch, which increases in 11 months to 316—381 pounds. Gilmore states the adhesion of Rosendale cement to the front bricks, after 28 days, when pure, to be 30 pounds, and mixed with one and two parts of sand, 16 and 12 pounds.

Clarke reports the tensile strength of Rosendale cements, pure:—

	Pounds.
After 1 and 12 months, as.....	115 to 290
And mixed 1:1 after 1 and 12 months.....	116 to 256
1:2 after 1 and 12 months.....	50 to 180
1:3 after 1 and 12 months.....	35 to 121
One cubic foot of Rosendale cement weighs.....	49 to 50

The proportion of tensile to compressive strength averages probably after one month 1:4, and rises probably, after two years, to about 1:6.—A. J. S.

Proceedings of the Austrian Society of Chemical Industry. Meeting of June 1, 1889. Chem. Zeit. 13, 781.

K. ZULKOWSKI criticised the work of Knapp on blast-furnace slag and Portland cement, in which the latter referred to the similar behaviour of the two materials when treated with dilute hydrochloric acid, ammonium chloride, magnesium chloride, or sugar, which dissolve lime freely from

them without bringing the corresponding amount of silica into solution. From this fact Knapp concluded that the lime so extracted is not in either material combined with silica. Zulkowski differs from this view. Twenty-six years ago he found that lime could be easily extracted, even by weak reagents, from basic aluminosilicate of lime which had been formed by heat, only inconsiderable amounts of silica dissolving at the same time. Again, Mylius and Foerster have shown that alkalis are dissolved out of glass by pure water, and that very little silica accompanies the alkali so dissolved. Water, further, dissolves lime from hydraulic lime, without it being thereby proved that the lime was present in the free state, a fact which can only be proved by a synthetical experiment. Zulkowski maintains the correctness of his theory, which is as follows:—

- (1.) That, in the burning of natural or artificial hydraulic lime, the clay is decomposed, with the formation of a basic silicate.
- (2.) When this basic silicate is fused, as in the case of blast-furnace slag, the whole of the lime becomes combined and the hydraulic property is lost.
- (3.) When the mixture is heated beyond fusion, there results a mixture of finely-divided lime and a fused or endry basic silicate, which, in presence of water, can again combine with the excess of lime.—E. B.

X.—METALLURGY.

Treatment of Quicksilver Ore Finest at Almaden, Spain. Eng. and Min. J. 47, 544—545.

CHANEL furnaces are employed for the treatment of fines rich in quicksilver at Almaden. The size of the fines for these furnaces must not exceed 10 cubic centimetres. The furnaces mentioned have the great advantage of being continuous in their operation, to such an extent that in seven months not the slightest interruption occurred.

The hearth is an inclined plane constructed of fire-brick, 2·50 metres in width by about 8 metres in length, the grade of which is equal to, or a little steeper than the natural slope of the fines. Every 40 centimetres this floor has a rise of 2 centimetres, as can be seen in the illustration. It is divided by partitions, formed of fire-brick, 30 centimetres high, into 12 channels, 12 centimetres wide, in which the ore runs. Transversely in the channels, and supported on their partitions, there are placed bricks, called "taws" ("stoppers"), which are above the floor of the hearth 4 centimetres, this being the thickness of ore in each channel. Arranged in the same way there are others, called "petacos" ("trunks"), situated immediately at the bottom of the rises and at the same distance from the hearth as the "stoppers," which serve to break up the fine ore on them so as not to present invariably the same surface to the action of the heat. On the lower part of the hearth there is another inclined plane, M, perpendicular to it. This is also divided into 13 channels, but there are no "stoppers" nor "trunks" on it. The ore, already calcined on the first plane, travels to the second, at the end of which, M, a boy is placed, whose duty is to make it run over the hearth. A little above the second plane, and facing the first, but separated from it by the bridge *x*, is placed the fire-place, the grate of which is divided into two equal parts by a partition, which rises to the arched roof of the fire-place. The fire-grate is formed of two systems of bars, *p, q* and *r, s*, the first placed lengthwise and irregular in height, and the second crosswise. The air for combustion passes in by the ash-pit to the fire-place, having traversed certain passages *e, f, g*, where its temperature has been raised by the heat taken from the walls of the furnace. By means of the hopper "T" the channels are filled with ore, and when it has been sufficiently exposed to the heating and reducing action of the gases, the boy placed at M withdraws

a portion of the ore placed on the lower edge of the second inclined plane. The ore remains subjected to the action of the heat about four hours. The calcined fines are ejected by a hopper to the passage G, whence they are taken out in

cars. They do not now contain more than two to four hundredths per cent. of quicksilver. The condenser is formed by two series of chambers, the first of which communicates with the furnace by a throat in the shape of a

FURNACE FOR CINNABAR FINES AT ALMADEN.

ENLARGED SECTION OF THE ABOVE.

truncated pyramid of iron plate protected with brick. The six chambers which constitute this first series are of brick, with thin walls, and are divided into partitions, which have openings arranged for the passage of the fumes, so as to run in double zigzag. The bottom of each division is formed of two inclined planes, whose intersection has a small incline towards a channel common to all the chambers in which is collected the quicksilver condensed in them. The bottoms are of iron plate in the three chambers nearest to the furnace, and of slate in those furthest away, this arrangement being in consequence of the iron being attacked

by the quicksilver in the latter. The last part of the condenser is formed of wooden chambers with glass, divided into four parts by vertical partitions. These chambers are arranged so that the air can circulate below and around the sides, and allow of observation in case of any filtration of quicksilver through the bottoms.

Coal was first employed as fuel, but coke is now found to give better results in regard to the smaller quantity of soot which is produced.—A. J. S.

The Platinum Metals. Eng. and Min. J. 47, 586—583.

Platinum.—Usually found in the form of small rounded and flattened grains. Platinum alloyed with other members of this group is found in small quantities in the beach sands and gold placers of the Pacific coast, and also associated with placer gold in Virginia, North Carolina, Georgia, and other southern States. In 1887 a nugget, weighing 104·1 grains, was described as found near Plattsburg, N.Y. Sperryite, a mineral containing platinum and arsenic, was discovered in the autumn of 1888, at the Vermillion mine, near Sudbury, Ontario, Canada. It was found to contain upwards of 7·52 per cent. of platinum. The greater part of the platinum that finds its way into commerce is derived from placer deposits in the districts of Soroblogodar and Nishni-Fagikk, in the Ural Mountains. Its refining is largely accomplished by the house of Johnson and Matthey, of London, where Deville's process is used, and the French corporation in Paris, formerly known as Quenessen, Le Brun, and Dessuontis. The method of mining is analogous to that of placer gold, with the exception that the apparatus for saving platinum depends upon gravity alone, and not upon gravity and amalgamation. From the material thus accumulated platinum is derived in the following method: The platinum is precipitated as a platinum-chloride of either potassium or ammonium in the nitro-hydrochloric acid solution of the crude metal. This substance washed with a little cold water, dried and heated to redness, or reduced in a current of hydrogen, leaves metallic platinum in a spongy state. The spongy platinum is made into a thin uniform paste with water, introduced into a slightly curved mould of brass, and subjected to a gradual pressure, by which the water is squeezed out, and the mass rendered at length sufficiently solid to bear handling. It is then dried, very carefully heated to whiteness, and hammered or subjected to powerful pressure, when the platinum will be in a state to bear forging into a bar. Deville and Delbray's method of refining consists in heating the crude metal in a crucible of lime by the oxy-hydrogen flame. All the impurities are separated in this way.

Palladium.—This metal is separated from the other members of the group by neutralising the acid solution, from which the platinum has been precipitated with sodium carbonate, and mixing with a solution of mercuric cyanide. Palladium cyanide separates out, and on being washed, dried, and heated to redness, yields metallic palladium in a spongy state. There has recently been described an alloy consisting of from 60 to 75 parts of palladium, 15 to 25 parts of copper, and one to five parts of iron, and its use recommended as suitable for the manufacture of watches owing to its non-magnetisable qualities. Other palladium alloys were described containing varying proportions of silver, gold, platinum, and nickel.

Rhodium.—From time to time it has been reported that rhodium occurs in small quantity in the amygdaloid rocks of Keweenaw Point, Lake Superior; but it is believed that its presence has not been authoritatively established. This metal remains in the solution after the platinum and palladium have been removed, and is separated in the following manner: The solution is mixed with hydrochloric acid and evaporated to dryness, when the residue is treated with alcohol of 0·837 density, which dissolves everything except the double chloride of rhodium and sodium. This is well washed with alcohol, dried, heated to whiteness, and then boiled with water, by means of which the sodium chloride is dissolved out, and metallic rhodium remains. It is a white coherent, spongy mass, less fusible and less capable of being welded than platinum. A small quantity of it in steel is said to impart most valuable qualities.

Iridium.—Its principal source is the mineral iridosmine, which, in America, is found chiefly in the placer washings of California and Oregon, where it accumulates with the gold on account of its weight, and is easily recovered and saved. When the crude platinum is dissolved in nitro-hydrochloric acid, a small quantity of a grey scaly metallic substance usually remains behind, having altogether resisted the action of the acid. This is the native alloy of iridium and osmium. It has been found in Cincinnati that by heating iridium or any of its ores in a sand crucible to a

white heat, and then adding phosphorus, the latter rapidly combined with the iridium, and in a few seconds the contents of the crucible were in a perfect state of fusion, capable of being poured and cast into an ingot. This material proved to be as hard as iridium, and seemed to have all the properties of the metal itself. The standard meter of Paris was made of an alloy consisting of 90 parts platinum and 10 parts iridium. Iridium has been used by the American Iridium Company, of Cincinnati, for the so-called diamond points upon gold pens, for the points of stylographic pens, for the knife edges of fine balances, for the tips of rubber turnery tools, for wire draw-plates in electric lighting, for the electric contact points of telegraphic apparatus, and, indeed, for any purposes where an exceedingly hard metal is required. Deposited electrolytically on base metals, it has been found to be exceedingly tough and susceptible of a high polish.

Ruthenium.—To obtain ruthenium, scaly osmiridium is heated to bright redness in a porcelain tube, through which a current of air (freed from carbonic acid and from organic matter) is drawn by means of an aspirator. The osmium and ruthenium are thereby oxidised, the former being carried forward as tetroxide and condensed in solution of potassium hydroxide, while the ruthenium oxide remains behind, together with iridium, and by fusing this residue with potassium hydroxide, treating the mass with water, and leaving the liquid in a corked bottle for about two hours to clarify, a solution of potassium ruthenate is obtained, which, when neutralised with nitric acid, deposits velvet-black ruthenium sesquioxide, and this, when washed, dried, and ignited in hydrogen, yields the metal.

Osmium.—When ruthenium and osmium are oxidised, the latter as tetroxide is passed in the form of a vapour into a solution of potassium hydroxide. This solution is mixed with an excess of hydrochloric acid and digested with mercury in a well closed bottle at 40° C. The osmium is then reduced by the mercury and an amalgam is formed, which, when distilled in a stream of hydrogen till all the mercury and calomel are expelled, leaves the metallic osmium in the form of a powder. Deville and Debray, by igniting precipitated osmium sulphide in a crucible of gas coke, at the melting heat of nickel, obtained it in bluish-black, easily divisible lumps.—A. J. S.

Note on the Influence of Temperature on the Mechanical Properties of Iron and Steel. A. Le Chatelier. Compt. Rend. 109, 58—61.

THE author has observed a noticeable change in the properties of iron and steel at a temperature above 80° and again a further one at about 240°. The change is permanent. There is an increase of elasticity and a notable reduction in the elongation. Thus three iron wires 2 metres long were loaded with 30 kilos. per square mm. at 15°, which gives an elongation of 9 per cent. No. 1 was now heated to 74°, No. 2 to 92°, No. 3 to 190°, each for 10 minutes. After cooling the following results were obtained:—

	Limit of Elasticity.	Load.	Elongation.
	Kilos.	Kilos.	Per Cent.
No. 1.....(74°)	33·5	38·2	21
No. 2.....(92°)	36·6	37·4	2
No. 3.....(190°)	40·0	41·6	4

Ordinary puddled iron drawn into thin wires was experimented upon and gave very irregular results, owing to minute particles of slag contained in the metal. The irons and steels used for the experiments referred to were of great purity. They contained 0·35 to 0·40 per cent. of manganese, and whilst the irons contained 0·05 per cent. of carbon, the steels contained 0·80 per cent. of that element.

—A. R.

Distilled Lead. R. Roosing. Chem. Zeit. 695—696.

The lead ores from Upper Silesia are specially suitable for the manufacture of pure lead, as they contain no bismuth or copper and only minute quantities of gold, antimony, arsenic, and nickel. Silver, zinc, and iron are present, but can be removed without difficulty. A sample of the lead produced by the distillation process at the Kgl. Friedrichshütte specially for chemical purposes, and from these ores, contained: Copper, 0.0007; antimony, 0.0006; arsenic, 0.0013; iron, 0.0010; traces of zinc, silver, bismuth, and nickel, lead (by difference), 99.9964 per cent.—E. E. B.

On the Nature of Cobalt and Nickel. Fleitmann. Chem. Zeit. 13, 757.

The author has repeated the experiments of Krüss and Schmidt with different kinds of commercial nickel and cobalt oxides, using as much as 50 grms., without obtaining a weighable quantity of the new metal. He has unsuccessfully endeavoured to obtain a sample from Krüss and consequently considers "Gnomium" as a phantasy. His own researches lead to the following conclusions:—(1.) If a new metal really exists as a general constituent of nickel and cobalt it cannot be present to the amount of 2 per cent. (2.) That this small quantity can have no real influence on the malleability of nickel, which in its usual purity is as weldable and malleable as the softest iron. (3.) That the patented process of Krüss is worthless, while it is not new and is partly impracticable.

If commercial nickel and cobalt in the form of hydroxides be treated with large quantities of caustic soda one obtains varying amounts of impurities which are usually present, together with small quantities of nickelous and cobaltous oxides. These impurities vary according to the source of the metal, but may consist of mixtures of lead oxide, zinc oxide, arsenious acid, manganic acid, molybdic acid, silica, alumina, cerium oxide, chromic acid, &c. The simultaneously dissolved nickel and cobalt oxides do not, as a rule, represent more than one-twentieth per cent. of the oxides taken. If they are separated from the remaining impurities which are dissolved by the alkali, and converted into nickelous and cobaltous oxides, they are found to be insoluble in caustic soda, by which it appears that their original solubility is due to the presence of some of the impurities, such as arsenious acid, silica, and alumina. If the original alkaline extract is treated with hydrochloric acid until the precipitate formed is redissolved, and then with ammonium carbonate, a complex mixture of different oxides and acids is obtained, which might confuse and mislead anyone not acquainted with such a mixture. It seems probable that Krüss and Schmidt had to deal with a similar mixture. The precaution taken by them to precipitate at a temperature below 10° C. strengthens Fleitmann's conclusion, since on warming precipitates are frequently formed, due to the manganic acid and the dissolved lead oxide being converted into manganic oxide and lead peroxide.—A. W.

Relative Merits of Different Lead-Tin Alloys for Soldering. J. Rothe. Mitth. Königl. techn. Versuchs. 1889, 86—87.

Two alloys were prepared from pure lead and Banca tin. A consisted of 10 per cent. of lead and 90 of tin, and melted at 210° C.; B was composed of 30 per cent. of lead and 70 of tin, and fused at 188° C. A was harder and less malleable than B, but behaved like it when subjected to bending tests; it gave the "cry" of tin, while in the case of B this property could scarcely be perceived.

Mechanical tests showed that A was as efficient a solder as B. Experiments with cast plates of the alloys exposed to the action of acetic acid indicated that at first B was more strongly attacked, and yielded more lead absolutely and relatively to the acid; after 24 hours tin was still freely dissolved from both alloys, but the amount of lead removed decreased considerably and became approximately constant and equal for both. It therefore appears that the lead

dissolved at the outset is reprecipitated by the more electro-positive metal, and is protected fairly completely by it subsequently.—E. B.

Servian Quicksilver.

The attention called to the new Servian quicksilver industry by the floating of the Avala Quicksilver Mines Company (Limited) in London recently, gave a recent visit made by us to the Servian section of the Paris Exhibition a more than passing interest. The Avala mines are situated fifteen miles south of Belgrade, and about two from the main railway line which connects that city with Paris and Constantinople. The mines are to be found at the foot of the mountain from which it takes its name, itself deriving its present name from an ancient castle, now in ruins, dating its origin to a century or two B.C., and with which many interesting legends are connected. The mines were discovered in 1883, the intervening five years having been spent in experimental working.

At the present time there are five veins of quartz in which the quicksilver is found, the largest of these being about 60 yards in width and 700 yards in length, the first mine having reached a depth of 100 yards. Nor is this all, for in the same mineral is found a considerable amount of sulphate of nickel, besides a certain quantity of the natural metal. One hundred and fifty thousand tons of mineral have been raised, giving an average yield of 27 lb. of quicksilver per ton, the whole of which is said to equal the best qualities found in the cinnabar mines of Almaden, Spain, and the New Almaden mines of California. Sixty miners and an engineer are constantly at work, the operations going on both day and night, now showing a daily raising of 15 tons. Four kilns and 10 retorts, with a powerful steam-engine, seem at present to constitute the principal working plant of the mine. At Avala the extraction of the metal from its ore is effected by oxidation and reduction, a process which appears to differ from that in use at Almaden, where great waste occurs, owing to an imperfect method of condensation, while at the Servian mines a loss of 6.6 per cent. only is sustained. Twenty-five bottles of quicksilver are produced weekly, each bottle containing 70 lb. net weight of the metal. These bottles have a similar form and style to those used in England for the nitrous oxide gas. Five hundred of them recently found a ready sale on the London market, while 200 have been despatched to China. At present, however, the company seems disposed to limit its sales to Vienna, where prices range somewhat higher than elsewhere, besides the great economy obtained in the matter of carriage, as compared with London, &c. It is not to be supposed that the company in question has been without competitors, but these, it would seem, from some unexplained reason, have not been successful. The principal one was the Kipanj syndicate. A former English concern, too, which worked the copper mines at Meidenpeck some years ago, came to grief; this was the first, and up to now the only, attempt by capitalists from this country to develop the mineral resources of Servia. We have searched in the United States and Spanish courts, consulted the officials, and perused the catalogues, but can hear of no other quicksilver exhibit. This is a matter of regret, as it would undoubtedly have been interesting to give some information from other sources.—*Chemist and Druggist.*

PATENTS.

Improvements in the Manufacture of Metallic Alloys. G. A. Dick, London. Eng. Pat. 2481, May 25, 1882. (Second Edition.) 6d.

See this Journal, 1883, 285.—H. S. P.

Improvements in or Relating to the Treatment of Ores for Facilitating the Extraction and Recovery therefrom of Gold and Silver, and in Apparatus therefor. W. P. Thompson, Liverpool. From H. F. Julian, Johannesburg, South Africa. Eng. Pat. 8332, June 7, 1888. 8d.

The finely pulverised ore is rotated in an air-tight barrel with water and chlorine, under a pressure of 60 to 80 lb. per square inch, produced by "air, steam, or other fluid."

Mercury is then introduced into the same or another barrel with the mud, and the whole again revolved under pressure. The contents are then run over copper plates to retain the amalgam, and, finally, the tailings are washed through a series of electrolytic cells in which the cathodes are mercury and the anodes carbon or other suitable material. These cells are arranged at different levels and overflow into each other. They are said to remove the last traces of gold, and catch any floured mercury or amalgam. Drawings are given.—A. W.

Improvements in Carburising and Coating Iron and Steel in the Form of Sheets, Hoops, Wrought or Cast Plates, Bars, or Manufactured Articles. J. Summerhill, St. Georges. Eng. Pat. 9848, July 6, 1888. 6d.

THE steel or iron articles are heated in an annealing furnace or muffle to as high a temperature as it is possible to attain without occasioning oxidation of the metal, and are then withdrawn and dipped into a bath of carbonaceous material, such as tar, pitch, or oil. The metal thereby becomes carburised and likewise coated with an adherent carbonaceous protective coating, which has a glazed appearance similar to Japan black when dried in the ordinary atmosphere, or a dull surface when artificially dried by heat. The most suitable bath is composed of approximately pure tar, containing 1 per cent. of Val de Travers rock. The time of immersion varies with the thickness of the material, and also with the desirability of carburisation with or without the production of the carbonaceous coating.

—A. W.

Improvements in Certain Metallic Alloys. E. L'Homme, Paris, France. Eng. Pat. 2722, July 19, 1888. 6d.

THE patent relates to the production of bronze or brass that possesses great hardness, toughness, and tensile strength, and which is capable of being rolled or otherwise worked in either the hot or cold state. The alloy consists of copper, iron, manganese, zinc, nickel, silicon, and carbon. The method of procedure is as follows:—In a suitable crucible or furnace are melted copper, nickel, ferro-manganese, ferro-silicon, and ferrocyanide of potassium, zinc is then introduced and thoroughly incorporated with other metals. The draught is then lowered and about 2 per cent. by weight of carbonate of soda is added, and a few minutes later the metal may be run off into moulds. The novelty consists in using ferrocyanide of potassium, whereby carbon is introduced into the alloy, and in the addition of a minute proportion of nickel to alloys of this class, which has the effect of lowering the melting point of the mass and increasing the homogeneity of the alloy. The proportions used are, to every 100 lb. of copper, 34–62 lb. of zinc, 4–6 lb. of ferro-manganese (containing 84 per cent. of manganese), 1–2 lb. of ferro-silicon (containing 44 per cent. of silicon), 2–4 oz. of nickel, and 10–30 oz. of ferrocyanide of potassium.—H. S. P.

Improvements in the Manufacture of Sodium and Potassium and the Apparatus therefor. W. G. Forster, London. Eng. Pat. 10,785, July 25, 1888. 6d.

THE patent is for apparatus used in the following process for making potassium or sodium. A reducing agent, such as carbon or carbon and iron mixed, is introduced gradually and from time to time, and preferably in a heated condition, into a bath of fused incandescent alkali, such alkali being either a carbonate or hydrate, or wholly or partially deprived of its hydrogen and oxygen by the use of finely-divided iron while in a fused condition. The invention consists of a contrivance for mixing the carbon with the fused alkali and preventing it from floating at the top of the bath. The alkali is fused in an upright cylindrical iron vessel *a*, fitted with a cover *g*. Into this vessel is placed a perforated iron disc *b*, of nearly the same diameter as the vessel. The disc is curved downwards at its rim and is attached to a hollow handle *c*, longer than the vessel. This handle passes through a stuffing box *f*, in centre of the cover, and by attaching it to

a chain and pulley or to a lever the disc may be moved up and down in the vessel, thus submerging the carbon and agitating the charge of alkali and carbon. The vapours and

gases generated in the process pass away by a pipe *i*, let into the cover of the vessel. The hollow handle of the disc is fitted with a loose cover and serves as a pipe for introducing the charge of alkali and the additions of carbon. It may also be used for discharging the waste alkali at the end of the reduction. For this purpose the loose cover of the hollow handle is removed and a short bend attached. The escape pipe for the vapours is then closed and the disc lowered nearly to the bottom of the bath. The confined gases then force the liquid residue up through the handle and through the bend into a suitable receptacle. Or, if preferable, coal gas may be forced into the vessel through inlet-pipe *j*, under sufficient pressure to expel the liquid residue. *k* is the stop-cock for pipe *j*. One of the chief advantages of the invention is that much larger vessels may be employed than those usually used in the manufacture of potassium and sodium.

The claims are:—1. In the manufacture of sodium and potassium, keeping the carbon submerged in the fused incandescent alkali by mechanical means. 2. The use of

apparatus, as described and shown, for the above purpose and for agitating the carbon with the heated liquid alkali, and allowing escape for the vapours produced in the process.
3. The improved apparatus.—H. S. P.

Improvements in Metallic Alloys. P. M. Parsons, Blackheath. Eng. Pat. 11,512, August 9, 1888. 4d.

THE patent relates to alloys of copper and zinc, or copper and tin, or copper, zinc, and tin together with steel, iron, and manganese, which last may be added as ferro-manganese or spiegeleisen, as described in Eng. Pat. 482 of 1876. The patentee now adds aluminium to such alloys, whereby their strength is increased, they are rendered more fluid when molten, and oxidation is diminished so that from such alloys very sound and sharp castings can be made. He finds that one-eighth of one per cent. of aluminium has an appreciable influence on the character of the alloy, and this amount may be increased with advantage to about two to three per cent. A still larger quantity of aluminium may be used if a very hard refractory metal is wanted, but at the same time the alloy becomes more brittle. These qualities may both be modified by reducing the tin or the zinc as the aluminium is increased. The aluminium may be added in any convenient way. For instance, after fusing all the other ingredients, pieces of aluminium may be introduced into the fused mass by means of a pair of tongs or other suitable appliance, and then, by stirring, the aluminium becomes melted and combines with the other metals.

—H. S. P.

A New or Improved Process for Extracting Gold, Silver, and other Metals from Refractory Ores, Sands, and Residues. E. de Rotterdam, Bludow, Russia. Eng. Pat. 12,074, August 21, 1888. 8d.

THE process consists of five operations:—(1.) Roasting; (2.) The extraction of the secondary metals; (3.) The removal of the protoxide salts; (4.) The extraction of the fine gold; and (5.) The final washing of the residue to collect the coarse gold. The roasting is carried on by preference in a Mueckell furnace, and is modified according to the nature of the ore. The roasted material is then leached with warm dilute sulphuric or muriatic acid, which "transforms the protoxides and salts at minimum of oxidation into oxides and salts at maximum of oxidation." The liquor obtained is treated with scrap iron by which the copper, silver, &c. are precipitated. The residue is submitted to the action of nascent chlorine by running in a solution of chloride of lime simultaneously with dilute hydrochloric acid, whereby a solution of chloride of gold is obtained which is at once run off to prevent further contact with the ore, "which would tend to reduce again to the metallic state the gold contained in the said solution." The solution also contains some silver, both which and the gold are extracted by ordinary methods. Any coarse gold remaining in the residues may be separated by mechanical means. The feature of this process is stated to be that only the most finely-distributed gold or that which is unobtainable by mechanical means is extracted by the chlorine, after which the coarse gold is recovered.—A. W.

Improvements in the Manufacture of Artificial Cryolite and similar Compounds. C. Netto, London, From C. Winkler, Freiberg, Germany. Eng. Pat. 12,135, August 22, 1888. 6d.

SLAG from the manufacture of aluminium from cryolite is melted with dehydrated sulphate of alumina in the proportion of 100 parts of the former to 32 parts of the latter, whereby the fluoride of sodium is decomposed with the formation of the double fluoride of sodium and aluminium according to the following equation:—

The sulphate of sodium is separated by lixiviation. Artificial cryolite can thus also be prepared from sodium or potassium fluoride in the first instance.—A. W.

A Method of Utilising Flux Skimmings from Galvanising Works. H. J. Kirkman, Swansea. Eng. Pat. 17,623, December 3, 1888. 4d.

ON treating the flux skimmings from galvanising works with water, zinc chloride and ammonium chloride pass into solution, leaving an insoluble residue containing zinc. The zinc may be recovered from this residue by any of the known processes. To the aqueous solution obtained as above described, lime (in the form of milk of lime), gas liquor, magnesia, sodium hydrate, sodium carbonate, or ammonia, is added in sufficient quantity. The precipitate of zinc hydrate or carbonate, as the case may be, thus formed, is separated from the solution, washed, dried, and, if need be, calcined. It may then be used as a pigment or the zinc may be recovered from it by the ordinary means. The solution, containing ammonium salts, may be treated by any of the known methods for the recovery of ammonia. Should any of the above mentioned substances, when added to the solution of the flux skimmings, decompose the ammonium salts and cause the evolution of ammonia, the solution may be treated in closed vessels and the evolved ammonia recovered by any of the known methods.—H. S. P.

Certain Improvements in the Amalgams, and Method of Applying the same, used in Amalgamation of Gold and Silver. M. Johnson, W. E. Field, and J. S. Beeman, Saint Kilda, Australia. Eng. Pat. 1602, January 29, 1889. 6d.

THE object of the invention is to prevent the "sickening" or "flooding" or "floating" of the mercury or amalgam used in extracting gold or silver, and in cases where the amalgam used has "sickened" or "floored," to cause the particles to remite or "quicken." The invention consists in adding a small quantity of zinc (or cadmium or magnesium or other suitable metal, sodium and potassium excepted) to the mercury to be used, and after mixing the zinc amalgam thus formed with the auriferous or argentiferous ores under treatment, pouring upon the mixture dilute sulphuric acid or hydrochloric acid or an aqueous solution of caustic potash or other suitable alkali, or of chloride of ammonium or any other suitable salt, so as to generate hydrogen on or from the surface of the amalgam. The proper proportion of zinc to be used with a given quantity of mercury so as to form the zinc amalgam varies according to the nature of the ores or material under treatment, and can only be determined by experiment. For many classes of ores it has been found that 1 part of zinc to 90 of mercury forms a suitable amalgam. The process may also be carried out by amalgamating the gold or silver first and then adding the pieces of zinc and the acid, alkali, or suitable salt, to the mixture in the amalgamating pan or after removal from the pan. Or by mixing the mercury and the ore and the acid or alkali and allowing the whole to flow over, on or under plates or "rilles" which are covered with zinc amalgam. Or the ore and mercury together with the acid or alkali may be mixed and triturated in a pan of zinc or covered with zinc.—H. S. P.

Improvements relating to the Galvanising of Metals and to Apparatus therefor. T. Midgley, Beaver Falls, U.S.A., and W. B. Nye, Boston, U.S.A. Eng. Pat. 8255, May 17, 1889. 6d.

THE material to be coated with zinc such as iron wire, sheets, pipes, &c., is made to pass, after having been cleaned with acid, through a bath of molten lead and upwards through a small body of melted zinc floating on the surface of the lead and confined within a small area by suitable moveable partitions. Drawings are given. The advantages claimed are: less oxidation of the zinc; less waste of zinc from the action of acids; a more flexible material, as the iron is not cold when it enters the zinc; and the prevention of the destruction of the pans usually employed for melting the zinc by confining the latter between partitions on the surface of the lead.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

PATENTS.

Improvements in Secondary and other Electric Batteries. H. Pieper, Liege, Belgium. Eng. Pat. 11,569, August 10, 1888. 6d.

To increase the capacity and efficiency of batteries they are subjected to a pressure considerably greater than that of the atmosphere, while in use; in the case of some gases, chlorine for example, sufficient pressure is maintained to liquefy them as they are formed by the electrolytic action. Sometimes the pressure is produced artificially by air, and at others by the gases themselves as they are given off in an hermetically sealed vessel.—B. T.

Improved Cell or Containing Vessel for Electric Batteries. H. G. C. Serrin, Paris, France. Eng. Pat. 12,163, August 23, 1888. 11d.

THE new cell is formed by making any number of cavities of the required size in a piece of natural wood of suitable size, and using each of these cavities as one cell of a battery. The battery can be used for any of the ordinary purposes, and can also have any desired apparatus mounted upon it.—B. T.

An Improvement in Electrical Batteries. W. Clark, London. From L. Maiche, Paris, France. Eng. Pat. 13,215, September 12, 1888. 4d.

A SOLUTION of citrate of ammonia, of varying strength according to circumstances, is used as the improved exciting agent.—B. T.

Improvements in or relating to Galvanic Batteries. G. C. Dymond, Liverpool. From C. Gassner, Mainz, Germany. Eng. Pat. 18,754, December 22, 1888. 4d.

AN isolated coal electrode is placed in a vessel of zinc, and the space is filled up with an exciting compound made by dissolving one part of sal-ammoniac and one of chloride of zinc in two parts of water, and then adding four parts of plaster powder, thus forming a thin pulp-like mass, which hardens in a short time.—B. T.

Improvements in Galvanic or Primary Batteries. C. Maltby-Newton, Croydon. Eng. Pat. 7356, May 3, 1889. 6d.

THE positive plates are made up of oxide of lead and syrup of sugar or molasses, the oxide of lead used consisting preferably of a mixture of flake litharge and powdered litharge.

The syrup and oxide are mixed up to a stiff paste, spread over each side of a perforated iron, copper, or lead gauze support, and baked. The negative pole consists of a plate of zinc, tin, or lead, and the whole is immersed in a solution of caustic soda contained in a vessel preferably made of iron.—B. T.

Dry Galvanic Cells. C. H. Mehner, Berlin, Germany. Eng. Pat. 7597, May 7, 1889. 4d.

A "MINERAL gelatin," which is in itself an excitant, is combined with the exciting solutions to form a pasty jelly-like mass suitable for a dry cell. This mineral is formed by adding magnesia to a concentrated solution of chloride of magnesium.—B. T.

Improvements in and connected with Electric Batteries. W. J. S. Barber-Starkey, Bridgnorth. Eng. Pat. 7619, May 7, 1889. 6d.

PLASTER of Paris is mixed with a suitable salt, such as the sulphates of sodium, potassium, or magnesium, soluble in the electrolyte, the mixture is quickly gauged and, while in the plastic state, placed in the cells between the plates. Upon the addition of water or the electrolyte the salt is dissolved out, leaving a very porous mass of plaster capable of absorbing a considerable quantity of the electrolyte and, at the same time, keeping the plates in one unalterable position. Porosity may also be gained by using some finely-divided fibrous material instead of the salt.—B. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Manganese Oxalate as a Drier. J. Castelaz. Chem. Ind. 12, 163.

MANGANESE oxalate, best obtained by treating the carbonate with oxalic acid solution, on heating with an oil to about 150° decomposes into carbonic acid, carbonic oxide, and oxide of manganese. By such treatment the oil gains in a high degree the capacity of drying. Whilst most of the driers hitherto used, when boiled with the oils, colour the latter, manganese oxalate can be used so as to yield almost colourless drying oils.—W. S.

Fatty Oil from Cyperus Esculentus. C. Hell and S. Twerdomedoff. Ber. 22, 1742—1745.

THE tubers of *Cyperus esculentus* contain, besides sugar, a considerable amount of fatty matter. The fat was extracted by means of petroleum ether, and was found to average 27.1 per cent. of the tubers. The oil is fluid at ordinary temperatures, yellow in colour, and possesses a smell somewhat similar to that of burnt sugar. When cooled below zero, a small quantity of solid glyceride separates. On saponification, the fatty acids were found to consist of oleic and myristic acids only, the bulk being oleic acid. The oil, therefore, seems to consist of the glyceride of oleic acid mixed with a little myristic glyceride.—H. T. P.

Improvements in the Manufacture of Soap and Detergents. J. J. Bowley, Battersea. Eng. Pat. 9857, July 6, 1888. 4d.

THE object of this invention is to render soap more cleansing and non-corrosive to the material washed. For this purpose kerosene, petroleum, or shale oil is added to ordinary soap.—E. J. B.

Improvements in Soap and Plasters. Edith Emily Gillam, South Kensington. Eng. Pat. 10,294, July 16, 1888. 4d.

THE object of this invention is to produce a disinfecting, antiseptic, anti-rheumatic, and antifebrile soap, by mixing together ordinary curd soap and from 10 to 20 per cent. of eucalypt oil.—E. J. B.

Cooling or Refrigerating Lubricating Oils, and Apparatus therefor. D. Crawshaw, Sale. Eng. Pat. 10,803, July 26, 1888. 6d.

WHEN heavy bearings are lubricated, the practice is to cause a copious flow of oil through the journal, the escaping oil being collected and pumped back to the journals. The re-use of the oil is open to the objection that it soon becomes excessively heated, and thus loses its viscosity and lubricating power. This is obviated by the use of a cooler consisting of a number of tubes immersed in cold water.

—E. J. B.

Improvements in or appertaining to Composition or Soap used for Cleansing and Disinfecting Purposes. J. Crossley, Liverpool. Eng. Pat. 12,001, August 20, 1888. 4d.

This improved composition consists of a mixture of soda crystals or ash, ordinary soap, and petroleum.—E. J. B.

A Blue Soap for Laundry Washing. G. R. B. Kempton, West Ham. Eng. Pat. 5680, April 3, 1889. 4d.

The object of this invention is to produce a blue soap, the use of which renders the subsequent employment of blue in laundry work unnecessary.

The inventor incorporates with ordinary soap a solution of aniline green in strong acetic acid. By the action of the alkali of the soap, the green is converted into blue, uniformly colouring the mass.—E. J. B.

Improved Apparatus for Rectifying Glycerin. R. O. Unglaub, Pendleton. Eng. Pat. 8196, May 16, 1889. 6d.

GLYCERIN vapour is made to pass through the cylinder A in the direction of the arrows. It is first made to

traverse the cylinders *b, c, d, e*, at the tops of which are the baffle plates *h, i, j, k*. Above these cylinders is a series of pipes *l*, fitted at the top with bonnets *m*. There is also a double row of pipes *n*, fitted with bonnets *a*, and traps *p*. The upper end of the cylinder is furnished with a safety valve *r*, opening inwards, and a pipe *s*, for drawing off the vapour.

The action of the apparatus is as follows: The impurities in the glycerin vapour condense on the surface of the cylinders, baffle plates, and pipes, and fall down to the bottom of the cylinder, where they are run off by the pipes *u, v, w*, the purified vapours being drawn off at the top and subsequently condensed.—E. J. B.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

On the Green Ultramarine. J. Szilasi. Ann. 251, 97—111.

According to the researches of J. Philipp, R. Hoffmann, and K. Heumann, blue ultramarine is a definite chemical compound. The author has tried to prove first by analysis and afterwards by preparing derivatives from the green ultramarine that the latter also is a chemical compound and not a mixture. He analysed three kinds of this substance obtained from two different sources. Under the microscope they appeared entirely homogeneous, they contained no free sulphur or iron, and were free from other admixtures. The results of the analyses were remarkable for the fact that all three agreed very well together. The author describes further some derivatives prepared from the *Green ultramarine*, *Silver ultramarine*, *Lead ultramarine*, and *Zinc ultramarine*. From these experiments he draws the conclusion that green ultramarine is a definite chemical compound.—A. L.

Painting on Cement Plaster. Sels. Chem. Zeit. 13, 696.

It is to be applied direct to plaster the caustic alkalis in the latter destroy the paint and make it peel off. Sulphate of iron (copperas) has been used to effect the so-called "killing" of the cement, the sulphuric acid of the copperas converting the caustic alkali or lime into sulphates, and thus destroying alkalinity, but a more efficient treatment is to soak the plaster with linoleic acid. When plaster so treated becomes dry any paint can be used with impunity.—E. E. B.

PATENTS.

New or Improved Composition or Liquid applicable for Preventing the Accumulation of Scale in Steam Boilers. J. W. C. Hamilton, Liverpool. Eng. Pat. 9324, June 26, 1888. 4d.

The composition is made by adding from two to eight ounces of the following mixture to one gallon of purified paraffin.

	Per Cent
Essential oil of citronelle	49
" " cassia	25
" " lemon	9
" " eucalyptus	17

In some cases about four per cent. of crude camphor may be added.—E. J. B.

An Improved Method or Process of Treating Steel, Iron, or any Combination of such Metals, to Prevent their Oxidising, Rusting, or Corroding. T. W. Helliwell, Brighouse. Eng. Pat. 9570, July 2, 1888. 4d.

The metal to be treated is heated "to about 600 degrees," whereby its "pores are opened," and immersed in a mixture composed of six pints of boiled oil, one "pint of fat," and one "pint of turpentine" for 5—15 minutes, then removed and either allowed to dry spontaneously or in an oven at "400 degrees." A second coating may be applied if desired. Metal treated thus is said to be protected from rusting or corrosion.—B. B.

Improved Coating or Preservative Material for Iron, Steel, and other Structures, or for Coating the Bottoms of Iron and Steel Ships or other Vessels, and Process for Manufacturing the same and other Products from Gas Tar. J. H. Eastman, Liverpool. Eng. Pat. 10,192, July 13, 1888. 4d.

Gas tar is freed from "ammonia and certain acids" alleged to militate against its employment as a preservative coating, by agitating it, heated to about 100° F., with water and calcium sulphate in the proportion of 20 gallons of water

and 10 lb. of calcium sulphate to 100 gallons of tar. The phenols form lime compounds, and the ammonia yields ammonium sulphate; the former are recovered by acidulating with sulphuric acid and extracting with light tar oils, and purified by re-solution in caustic soda, removal of the neutral oils, and reprecipitation by sulphuric acid; the latter is obtained from its aqueous solution by evaporation.

The purified tar is mixed with one-tenth of its bulk of light petroleum, or coal-tar naphtha, and used as a preservative material for iron and steel.—B. B.

An Improved Compound for removing Paint from Painted Surfaces. P. Brentini, London. Eng. Pat. 11,398, August 7, 1888. 4d.

Four pounds of Irish moss, 3 lb. of methylated spirit, and 3 lb. of fuller's earth are mixed with 30 lb. of water, the whole boiled, and a solution of 16 lb. of caustic soda and 16 lb. of caustic potash dissolved in 28 lb. of water added, after which the product is stirred until it is cold and has solidified to a brownish gelatinous mass. The proportions of the ingredients may be varied. The compound is used by applying it to the painted surface with a brush, allowing it to remain thus for 20 minutes to one hour, and then washing it off together with the paint that has been disintegrated by its action.—B. B.

An Improved Varnish for Cleaning and Preserving Harness and other Leather Goods. S. B. Reswick, Birkenhead. Eng. Pat. 11,579, August 11, 1888. 4d.

Four ounces of shellac, half an ounce of camphor, and one ounce of rosin are dissolved in one pint of methylated spirit and shaken at intervals for 48 hours. The mixture is then coloured according to the kind of leather with which it is to be used. Other rosins, solvents, and proportions may be adopted.—B. B.

XVI.—SUGAR, STARCH, GUM, Etc.

The Amylodextrin of W. Nägeli, and its Relation to Soluble Starch. H. T. Brown and G. H. Morris. Chem. Soc. J. (Trans.) 55, 449—461.

AMYLODEXTRIN was first described by W. Nägeli in 1874. He obtained it by the long-continued action of dilute acids upon ungelatinised starch in the cold, when the residue was found to consist of amylo-dextrin. It was obtained in a pure state by treating this residuum with hot water and precipitating the solution with alcohol. Nägeli describes amylo-dextrin as separating from its solutions in crystalline spherules, made up of minute needles arranged radially. He assigned to the pure substance a rotatory power of $[\alpha]_{175}^{\circ} 175^{\circ}$ — 177° , and stated it to be non-diffusible. Of late years chemists have taken it for granted, mainly on the authority of Musculus and Gruber, and of A. Meyer, that amylo-dextrin is identical with soluble starch and the so-called starch cellulose.

The authors have now submitted this substance to a careful examination, and whilst failing to confirm in all respects Nägeli's statement regarding its properties, they have shown that it is a body of definite chemical composition, and have determined its relation to soluble starch, with which it certainly is not identical.

The authors show that when ungelatinised potato starch is treated in the cold with hydrochloric or sulphuric acid of about 10—12 per cent., little or no change can be observed in the microscopical appearance of the granules during a period of about 21 days. Notwithstanding this fact, the starch has been profoundly modified in its properties. Within about 24 hours of the commencement of the experiment the granules are found to have lost their power of forming a viscid paste with hot water; they dissolve to a perfectly limpid solution, and the substance which separates out on evaporation and cooling is found to have all the

properties of the soluble starch prepared by the limited action of diastase or dilute acid upon starch-paste at elevated temperatures. It is entirely without structure, and in the solid state has no influence on polarised light. It is coloured intense blue by iodine, both in solution and in the solid state, and it has a specific rotatory power in solution of $[\alpha]_{333}^{\circ} = 216^{\circ} 0'$, and no cupric reducing power. When the digestion with acid has proceeded for a few days, the altered starch substance is found to have a gradually decreasing optical activity, whilst at the same time it acquires the property of reducing Fehling's solution, a property which goes on steadily increasing up to a certain point. Meanwhile the iodine reaction of the granules changes from a deep blue, through purple, reddish-purple, and reddish-brown to a final pale yellowish-red. After about three weeks' digestion the starch granules commence to disintegrate, and this action, which takes place principally along their lines of stratification, is complete in about three months. Chemical alteration of the residue continues for some time longer, but a point is ultimately reached beyond which no further change takes place.

The residue left after some months, representing about 60 per cent. of the starch originally taken, consists almost entirely of the so called amylo-dextrin. Purified by solution in water and precipitation with alcohol it gave the following numbers on analysis:—

$$[\alpha]_{336} = 206^{\circ} 25'$$

$$K_{336} = 9^{\circ} 07'$$

The authors then show that its composition can be expressed in terms of maltose and dextrin; it thus conforms to the rule previously established by them (Chem. Soc. J. (Trans.) 47, 538) for all starch transformation products. Its composition is:—

Maltose	-	14.87	which requires	$[\alpha]_{336} = 205.4$
Dextrin	-	85.13		$K_{336} = 9.07$
		100.00		

Brown and Morris state that one of the best marked properties of amylo-dextrin is that of forming spherocrystals, which are very beautiful in form when the substance is slowly separated out from solution. These spherocrystals resemble in their appearance so closely those of inulin that it is impossible by mere microscopic examination to distinguish between the two. That amylo-dextrin is really a homogeneous substance, and not a mixture, was proved in the following ways:—

- (1.) It is absolutely unfermentable, and therefore cannot contain free maltose.
- (2.) It cannot be differentiated by fractionation of its solutions with alcohol, nor by methods of partial solution.
- (3.) The same is true with regard to dialysis. Contrary to Nägeli's statement, the authors find that amylo-dextrin is sensibly diffusible, and passes through the dialyser unchanged.

These facts, coupled with its distinctly crystalline nature, convinced the authors that they had to do with a perfectly definite substance, and a critical examination of the various stages in the production of this substance showed that it is derived from the partial or limited hydrolysis of soluble starch, the first product in the reaction. This partial hydrolysis of the starch ceases when a certain point is reached, the final product being amylo-dextrin.

Amylo-dextrin closely resembles in constitution and properties the malto-dextrin described by the authors in 1885 (Chem. Soc. J. (Trans.) 47, 538). Thus when treated with diastase or malt-extract both these substances are completely hydrolysed to maltose, whilst the authors have shown in their previous papers that starch, even under the most favourable conditions, leaves a residue of one-fifth of highly stable dextrin. Malto-dextrin was represented by Brown and Morris as consisting of one amylin- or maltose-group united to two anylin- or dextrin-groups. Thus:—

Amylodextrin can be represented in the same manner, and the authors' results show that it is made up of *one* amylin- or maltose-group united to *six* amylin- or dextrin-groups. Thus:—

$$\left\{ \begin{array}{l} C_{12}H_{22}O_{11} \\ (C_{12}H_{20}O_{10})_6 \end{array} \right\}$$

Calculated. Found.

which requires $[\alpha]_{D}^{20} = 206.11$ 206.25

$K_{D}^{20} = 9.08$ 9.07

whilst a determination of the molecular weight by Raoult's method gave—

$$\begin{aligned} \Lambda \text{ (coefficient of depression)} &= 0.0086 \\ M \text{ (molecular weight)} &= 2220.0 \end{aligned}$$

The above formula requires $M = 2286$.

Amylodextrin is differentiated from the two substances with which it has been confounded—soluble starch and the so-called starch cellulose—by its solubility, its iodine colouration, its crystalline structure, and its behaviour with diastase and with acids.—G. H. M.

The Determination of the Molecular Weights of the Carbohydrates. Part II. H. T. Brown and G. H. Morris. Chem. Soc. J. (Trans.) 55, 462–471.

THE authors first draw attention to the fact that the results given in their first paper on this subject have been confirmed by Tollens and Mayer (Ber. 21, 1566 and 3503), and by de Vries (Compt. Rend. 106, 751); they then give their later experiments in which a thermometer graduated to one-fiftieth of a degree, and capable of being accurately read to 0.004° C., was used.

Galactose, $C_6H_{12}O_6$, $M = 180$.

—	Calculated for $C_6H_{12}O_6$	Found (Mean).
Λ (coefficient of depression) ..	0.106	0.1073
M (molecular weight)	180.0	177.0

Inulin, $n C_6H_{10}O_5$ or $C_{36}H_{62}O_{31}$.

It has been generally considered that the formula $n C_6H_{10}O_5$ expressed the constitution of inulin, but the recent researches of Kiliani indicate that a formula whose simplest expression is $C_{36}H_{62}O_{31}$ or $6 C_6H_{10}O_5 + H_2O$ is more probably correct. The numbers obtained by Raoult's method were:—

—	Calculated for $2 C_{36}H_{62}O_{31}$	Found (Mean).
Λ	0.0006	0.0088
M	1980.0	2150.0

From all the facts, and the great similarity between inulin and amyloidextrin (see preceding abstract) the authors attribute the following formula to the two substances—

Inulin, $M = 1980$. Amyloidextrin, $M = 2286$.

The amylin- and amylin-groups in the two compounds possess very different optical properties, and behave differently with regard to cupric reduction. The ultimate products of hydrolysis with dilute acids are also very different, being in the one case levulose, and in the other dextrose.

Amyloidextrin, $\left\{ \begin{array}{l} C_{12}H_{22}O_{11} \\ (C_{12}H_{20}O_{10})_6 \end{array} \right\}$, $M = 2286$.

See preceding abstract.

Maltodextrin, $\left\{ \begin{array}{l} C_{12}H_{22}O_{11} \\ (C_{12}H_{20}O_{10})_2 \end{array} \right\}$, $M = 990$.

This substance was described by the authors in 1885. Submitted to Raoult's method it gave the following numbers:—

—	Calculated for $\left\{ \begin{array}{l} C_{12}H_{22}O_{11} \\ (C_{12}H_{20}O_{10})_2 \end{array} \right\}$	Found (Mean).
Λ	0.0131	0.0197
M	990.0	965.0

Starch, $n (C_6H_{10}O_5)_n$.—The authors found it impossible to apply Raoult's method to starch-paste; solutions of soluble starch produced so slight a depression that no reliable results could be obtained; a number of concordant results pointed, however, to a molecular weight of 20,000 to 30,000. In order to ascertain whether the failure in this case was due to a high molecular weight, or to the inapplicability of the method to colloid substances, the authors examined an arabic acid, having a rotatory power of $[\alpha]_D = +61.16$; this gives results pointing to a value for M of 717, thus rendering it most probable that the small influence exerted by soluble starch on the freezing point was due to its high molecular weight.

Indirect evidence of the size of the soluble starch molecule was then sought from an examination of the dextrins. In former papers the authors have shown that when starch is broken down by diastase, a resting-stage in the reaction is reached when the amount of dextrin present in the conversion corresponds to one-fifth of the weight of the starch taken, and they have also shown from this and other facts that the molecule of soluble starch must be five times the size of the molecule of this stable dextrin. Determinations of several preparations of this dextrin gave the following numbers:—

—	Calculated for $20 C_{12}H_{20}O_{10}$	Found (Mean).
Λ	0.0029	0.0030
M	6180.0	6221.0

Consequently the value of soluble starch would be five times this, namely, its formula would be $5 (C_{12}H_{20}O_{10})_{20}$ and its molecule weight 32,400.

The size of the starch molecule having been as far as possible determined in this indirect way, the authors turned their attention to the dextrins. It is usually considered that these substances constitute a polymeric series, and it was endeavoured to apply Raoult's method to the solution of this question. A number of the higher dextrins were prepared from starch transformations stopped at an early stage of hydrolysis, and examined. All the results obtained show that the freezing method affords no evidence of there being any difference in molecular size between the so-called high and low dextrins, the numbers being, in fact, almost identical with those given above.

From a consideration of the results obtained with soluble starch, and with dextrins of varying position in the series, the authors conclude that the evidence points to the conclusion that the dextrins are metameric, and not polymeric compounds, as was suggested by O'Sullivan in 1879. They therefore abandon their former working hypothesis of the hydrolysis of starch by diastase, and now consider the starch molecule to consist of four complex amylin-groups, arranged round a fifth similar group, which constitutes a molecular nucleus. When hydrolysis takes place this complex is broken up, four amylin-groups being liberated; these are capable in turn of undergoing further hydrolysis into one or more malto-dextrins, and ultimately into maltose, whilst the fifth amylin-group, which constituted the nucleus of the original molecule, resists the action of hydrolysing agents, and forms the stable dextrin of the No. 8 equation.

The authors therefore assign to each amylin-group of the five, the formula $(C_{12}H_{20}O_{10})_{20}$ corresponding to a molecular weight of 6,480; the molecule of soluble starch being thus represented by the formula $5(C_{12}H_{20}O_{10})_{20}$ which corresponds to a molecular weight of 32,400.—G. H. M.

Pentacetyl-dextrose. E. Erwig and W. Koenigs. Ber. 22, 1464—1467.

Up to the present time the only crystalline derivatives of grape-sugar known, which prove the presence of five OH-groups in the carbohydrate are aceto-chlorhydrate, $C_6H_5OCl(OC_2H_5O)_4$ and acetonitrose $(OC_2H_5O)_4C_6H_7O$, (ONO_2) , neither of which crystallises very readily.

The authors have succeeded in obtaining a pentacetyl-dextrose by boiling pure grape-sugar (5 grms.) for 10 minutes with acetic anhydride (20—22 cc.), and a trace of zinc chloride; the yield is good.

As pentacetyl-dextrose crystallises well, and can be easily obtained in a pure state, its formation can be employed for the identification of grape-sugar.—F. S. K.

The Inversion Products of Melitose (Raffinose). C. Scheibler and H. Mittelmeier. Ber. 22, 1678—1686.

According to the observations of different chemists, it seems probable that melitose yields on inversion a mixture of three glucoses: galactose, dextrose, and levulose. The inversion may take place either in one or two stages, as shown by the following equations:—

I.

II.

By the action of very dilute sulphuric acid, melitose is split up according to the first equation under II. That the reaction takes this course was shown by the fact that the osazone prepared from the inversion products could be separated into two portions, one soluble, the other insoluble in hot water. Now, according to E. Fischer, the osazones of the simple glucoses are all insoluble in hot water, whilst the diglucoses, such as milk sugar, yield an osazone soluble in hot water. The glucose formed was levulose. The diglucose produced has apparently the composition of milk sugar, but a closer examination proved it to be a new body. Its specific rotatory power, as calculated from the optical activity of the products of inversion, is considerably higher than the specific rotatory power of lactose. Its osazone is a yellow powder, melting, when quickly heated, at 176° — 178° C. Lactosazone melts at 200° C. The new osazone is fairly soluble in hot alcohol, but separates slowly on cooling. It is difficultly soluble in ether, chloroform, and benzene, easily soluble in warm strong acetic acid, forming a dark red solution. So far the authors have been unable to obtain the new sugar in the crystalline state. They propose to name it "melibiose." The complete inversion of melitose requires protracted heating with sulphuric acid, the solution becoming very yellow in colour, and a small quantity of humin substances being separated. The mixed osazones prepared from the products of inversion were practically insoluble in hot water, and melted at 200 — 201° C. (Compare this Journal, 1887, 445).—H. T. P.

The Oxidation of Rhamnose (Isodulcitol) by Nitric Acid. W. Will and C. Peters. Ber. 22, 1697—1704.

MALIN obtained, by the oxidation of rhamnose with strong nitric acid, an acid of the formula $C_6H_{10}O_8$. This result is incompatible with the present view of the constitution of rhamnose, which is considered to be an aldehyde of the formula $C_6H_{12}O_5 + H_2O$. The authors have, therefore, re-investigated the subject, and find that the chief product

of the oxidation of rhamnose by nitric acid is trihydroxy-glutaric acid. The potassium salt of the acid was prepared, and found to be in every respect identical with the potassium salt of trihydroxyglutaric acid, as described by Haushofer. The calcium salt, $C_6H_7O_8(Ca + 3H_2O)$, is prepared by mixing a strong solution of the potassium salt with calcium chloride. The barium compound is prepared in a similar way. On adding lead nitrate to a dilute solution of the potassium salt, a white amorphous precipitate of the lead salt is obtained. The silver compound obtained in a similar manner is a voluminous, colourless precipitate, rapidly changing to the crystalline state. The formation of this acid settles any doubts as to the constitution of rhamnose, and proves it to be $CH_3.CHOH.CHOH.CHOH.CHOH.CO.H$.

In a former paper the authors described a lactone, $C_6H_{10}O_5$, obtained by the action of bromine and water on rhamnose. This body was very similar to Kiliani's meta-saccharin. The authors have prepared crystals of the body, and find it to be totally different to meta-saccharin.

PATENTS.

Process and Apparatus for obtaining Sugar Liquor from Sugar Cane, or for obtaining Extracts. H. A. Hughes, Rio Grande, N.J., U.S.A. Eng. Pat. 7131, April 29, 1889. 8d.

THE main feature in this invention is the manner in which sugar cane, or sorghum, is subjected to the process of diffusion. In this case the diffusion battery consists of a series of shallow round cells placed in an annular tank provided with a cover, to which the cells are attached, the annular tank serving as a steam or hot-water jacket to the cells. By means of a crane with horizontal arms arranged round a vertical shaft placed in the centre of the battery system, baskets made of perforated sheet copper, and containing the cane chips, are placed in the cells, which contain water, in rotation, the chips being exhausted when they leave the last cell. When the liquor in the first cell is sufficiently dense it is drawn off and the cell refilled with water, the process being carried out in the well known systematic manner. To avoid the gradual removal of water from the first cell, if the chips were introduced dry, the baskets containing the chips are first dipped into another tank of strong sugar liquor before being introduced into the regular battery cells. Apparatus is also described for removing the leaves from the canes and cutting and shredding the stalks. Detailed drawings accompany the specification.—W. M.

Apparatus for Refining Loaf Sugar in the Moulds. C. Steffen, Vienna, Austria. Eng. Pat. 8052, May 14, 1889. 8d.

THE apparatus consists of "a series of moulds with or without sieves at their apex according to the kind of sugar used, that is sugar in hard crystallised form, or in the form of granular pulpy mass, arranged one above the other so as to form an air-tight fitting column-like battery, into the upper mould of which the lixiviating fluid, consisting of a saturated solution of pure sugar, is led, from whence the said fluid descends through all the moulds in the said battery, and leaves the last mould as an impure syrupy fluid, the moulds in the said battery being exchanged by removing the uppermost mould containing perfectly refined sugar, and inserting a fresh mould, charged with sugar to be treated, at the lowermost end of the battery."

Compressed air is used to force the liquor out of the uppermost mould when it has been sufficiently refined. Drawings accompany the specification clearly showing the mechanical carrying out of this process.—W. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

PATENTS.

Improvements in the Rectification of Alcohol. A. T. Christophe, Paris, France. Eng. Pat. 12,642, September 1, 1888. 6d.

PREVIOUS to distillation the spirit is treated in the cold with sodium amalgam, or with an alloy of sodium with tin, lead, or other suitable metal. Calcium hypochlorite (bleaching powder) is also added. The operation is best conducted as follows: The spirit is placed in a large vat provided with stirring apparatus, and diluted with water to about 10 per cent. strength. Bleaching powder is then stirred in at the rate of 1 gram. per litre of the diluted spirit. After standing some minutes the sodium amalgam or alloy is added in such quantity that about 15–20 grms. of sodium are present per 100 litres of the spirit. The stirrers should be kept in motion for half an hour or more. After some time the spirit is transferred to the rectifier and distilled in the usual manner. It will be found that the good spirit comes over at an earlier stage than usual, and the yield is larger and better in quality.—H. T. P.

A Process for Producing Extract of Hops, and for the Preparation of a Beverage or Beverages therewith. L. Groezinger, Stuttgart, Germany. Eng. Pat. 13,212, September 12, 1888. 6d.

THE resinous matters are first removed by means of spirits of wine. The extraction is carried on in wooden or tinned vessels provided with false bottoms and taps for drawing off the liquor. The hops are tightly packed in and covered with four parts of alcohol to one of hops. After two days the extract is run off and the hops pressed. The hops are next boiled with water in a copper boiler. The hops are placed on three trays made of woven tin wire stretched over tin hoops. These trays rest on projections inside the boiler and can be removed at will. The pressed hops are shaken out and placed between the divisions of the boiler and boiled with 15 parts of water for every one part of original hops. After half an hour the extract is run off, and the extraction continued with a fresh portion of water, and so on. The decoction so made can be clarified with gelatin, albumen, &c., in the usual way. To make beer from this extract, malt-sugar and colouring matter are added, and the mixture is filtered and aerated with carbonic acid gas. The extract may also be employed to improve fermented beer at any stage of its preparation. For this purpose a stronger extract may be made by mixing the spirit infusion with the first and second decoctions, and taking only 6–8 parts of water in the preparation of these decoctions.—H. T. P.

Improvements relating to Apparatus for the Pasteurisation of Beer, Wine and other Liquids. W. Kuhn, Clermont-Ferrand, France. Eng. Pat. 15,261, October 23, 1888. 11d.

THE apparatus consists of a large copper cylinder surrounded by a sheet iron jacket or outer cylinder, the whole being arranged horizontally. The ends of the two cylinders can be easily taken off, so as to allow of the apparatus being cleaned. A large copper coil occupies the whole length of the inner cylinder. One end of the coil passes right outside the apparatus; the other end communicates with the space between the two cylinders. The apparatus is provided with a pressure gauge, two thermometers, and a number of taps for the entrance and exit of beer, gas, and heating and cooling water. The whole is supported on iron feet. The beer to be pasteurised is filtered and forced into the apparatus at the bottom. When full, the tap is closed, and hot water is circulated through the coil and jacket. When the beer has been brought to the desired temperature and pressure, it is again rapidly cooled by passing cold

inconvertible liquid through the coil. Pure air or carbonic acid gas is then forced into the apparatus, and the beer transferred to sterilised and hermetically closed casks. These cylinders may also be combined in sets of three, the liquid to be sterilised being heated in the first, partially cooled in the second, and completely cooled in the third. An arrangement is described in which the coils are placed vertically. It consists of three copper vessels superimposed and provided with coils, casings, &c. as before. The beer is heated in the top vessel, and passes through the middle and bottom vessels, in which it is cooled. A third apparatus is described, by means of which a continuous flow of sterilised beer may be obtained, without loss of gas. It consists of three vertical cylinders with coils, &c., each preceded by an additional coil. Between each set of two coils, and also at the beginning and end of the apparatus, there is a pump. Beer is forced continuously through the apparatus. It is sterilised in the first two vessels, and cooled in its passage over the second and third set of coils. No escape of carbonic acid can take place at any stage, for the pump-valves are so arranged that when one is open the preceding and following ones are closed.—H. T. P.

Apparatus for Supplying Carbonic Acid Gas to Liquors in Casks or other Receptacles. H. Hürtter, Coblenz, Germany. Eng. Pat. 5940, April 6, 1889. 6d.

THE apparatus consists of a wrought-iron gas cylinder, open at one end, in which a valve is screwed. A narrow passage connects the reservoir with the valve chamber. A screw spindle passes through a stuffing box into the valve chamber. The spindle terminates outside in a triangular head, so that by means of a key it can be screwed right down on the narrow opening leading from the reservoir, closing it. The valve chamber is provided with a lateral opening, by means of which the reservoir is filled and emptied. To provide means for fixing the apparatus in cask, the nut at the top of the valve chamber carries a tube, which is screw-threaded outside. Having filled the cylinder through the side passage, the valve is screwed down and protective caps screwed on the lateral opening and over the valve. The apparatus may be kept filled for an indefinite time. To insert the apparatus in a barrel, the latter is provided with a screw bung, having an opening closed by a screw plug. The bung is unscrewed, the apparatus screwed in place of its inner plug, so that the head of the valve may be reached through the opening in the bung: the apparatus is passed into the cask, and the outer bung now carrying the apparatus screwed fast. By turning the spindle from the outside by means of the key, the gas will escape inside the cask.—H. T. P.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

PATENT.

An Improved Manufacture of Cattle and other Food. A. W. MacIlwaine, Kingston-on-Hull. Eng. Pat. 10,488, July 19, 1888. 4d.

By extracting the residue from the preparation of mustard from mustard seed, by means of volatile solvents and steam, the inventor renders it fit for admixture with cattle and other food.—E. J. B.

(B)—SANITARY CHEMISTRY.

PATENT.

Improvements in the Method of applying Soluble Disinfectants and Antiseptics, and in means therefor. R. Le Neve Foster, Manchester. Eng. Pat. 7602, May 7, 1889. 4d.

SOLUBLE disinfectants in a solid form, e.g., carbolic, cresylic or other tar acids, are enclosed in a cage of wire work or perforated metallic sheeting, such cage being either floated on the liquid to be impregnated or fixed at the normal fluid level thereof.—C. C. H.

(C)—DISINFECTANTS.

PATENT.

Improvements relating to the Utilisation of Peat for Antiseptic and other Purposes. C. Rutten, Grivepécé, Belgium. Eng. Pat. 11,465, August 8, 1888. 6d.

PEAT has long been used as a dressing for wounds, but though it possesses surprising healing qualities it has not been largely used on account of its inconvenient character. The present invention remedies this by producing a peat wadding. After dessication the raw peat is heckled to remove knots, then beaten and mixed with a small quantity of cotton, hair, or wool, or other suitable material, to give more cohesion to the finished mass; it is carded. Finally, it is slowly boiled in water, with or without the addition of antiseptics, such as corrosive sublimate, and carded into a uniform nap of wadding; this renders it soft, pliable, and absorbent, without detracting from its valuable properties as a surgical bandage.—C. C. H.

XIX.—PAPER, PASTEBOARD, Etc.

Aluminous Cake: Its Composition and Use in Paper Making. Chemical Trade Journal, 5, 158.

SULPHATE of alumina is extensively used in the sizing of paper pulp in the beater engine. There is a large home consumption of aluminous cake, and also a large export trade between this country, the Continent, and America. Its application is confined to the manufacture of cheap printing papers. For finer grades of paper it might also be used providing not too much per ton of paper were required and that it were free from iron. Its mode of preparation is as follows:—

The china clay is first of all calcined by being heated on the bed of a reverberatory furnace until all hygroscopic, and practically the whole of the combined water has been driven off. The calcined clay is now withdrawn and cooled, and consists essentially of an anhydrous silicate of alumina, together with other substances which, in our particular case, may be looked upon as impurities, namely, a small percentage of lime, and a little silicate of iron, a portion of which, however, is doubtless decomposed during the calcining operation. The calcined clay is then removed when cold, and is finely ground in a mill suitable for the purpose, the ground portion being riddled upon a very fine sieve. The coarse granules of clay, which do not pass through the sieve, return to the mill and are re-ground, whilst the sieved portion is used for mixing with the oil of vitriol. This mixing of the clay with the oil of vitriol is the most important operation in the preparation of aluminous cake, and is generally carried out according to exact measurement in large cast-iron vessels or vessels of other material lined with lead and fitted with agitators with which the mixture is stirred. The clay is introduced into the "mixer" simultaneously with the acid in suitable proportions, the acid being of suitable strength. A very violent reaction takes place, in which the sulphuric acid splits up the silicate of alumina

(clay), liberating the silica, and combining with the alumina to form sulphate of alumina. Any lime, and indeed the greater part of the silicate of iron, also oxide of iron, which are present in the calcined clay, are also acted upon, forming soluble salts, which, as a matter of fact, constitute the impurities of aluminous cake. After the violent action has subsided, and the thick putty-like mass begins to get stiffer, the charge of clay and acid is dropped through a door in the bottom of the mixer into a large iron waggon with moveable sides, where it is kept warm and allowed to remain for twelve or more hours to enable the chemical action to cease. After the lapse of this time the moveable sides of the iron waggon are removed, and the mass of aluminous cake, which is still hot and comparatively soft, is loosened, and by means of a screw worked automatically with suitable machinery, is pushed forward about half an inch at a time underneath the knife of a huge guillotine, which cuts the face of the block in a vertical direction as the knife descends, the aluminous cake falling in fragments into a waggon placed immediately underneath. The cut cake is then stored in heaps until it appears dry, or until all further possibility of the acid acting upon the clay has ended. In this state it is placed in bags and sold to the paper makers. Its composition is fairly regular, and may be represented by the following analyses of the English-made article:—

ANALYSES OF ALUMINOUS CAKE.

	"A."	"B."
Sulphate of alumina	Per Cent. 41.80	Per Cent. 39.49
Free sulphuric acid	84	2.65
Sulphate of peroxide of iron	45	50
Silica, undecomposed clay, &c., or substances insoluble in water	24.90	20.48
Water, lime, magnesia, less, &c.	32.01	36.97
	100.00	100.00

The quality of "A" is superior to that of "B," because it contains considerably more sulphate of alumina, less free sulphuric acid and sulphate of peroxide of iron, and more insoluble matter. The amount of free acid in "B" is very high and is really unusual. Where it contains this ingredient in such quantity the aluminous cake is somewhat soft and appears damp and dull in colour.

Aluminous cakes seldom contain much sulphate of lime, and if they do, this impurity does not affect their applicability in the manufacture of paper. Nor, indeed, does the presence of a small quantity of free acid such as that contained in "A," because it can always be neutralised by the soda contained in the resin size used along with aluminous cake in the process of sizing paper pulp. Excepting dirt, the sulphate of peroxide of iron (ferrie sulphate) is the only impurity which the cake usually contains, and it is this towards which the paper maker has such an objection. As a matter of fact, however, the purposes for which aluminous cake is used are such as not in most cases to be influenced by the presence of a small quantity of sulphate of iron like that which exists in ordinary aluminous cake. The iron salt will, of course, have a telling effect upon the finished paper, should it be present in abnormal quantity, say to the extent of four or five per cent., but as a general rule it does not contain anything like this quantity. The amount of anhydrous sulphate of alumina which it usually contains is from 40 to 42 per cent. (equal to from 11.93 to 12.52 per cent. of alumina (Al_2O_3)). This sulphate is the real sizing material, and that for which the cake is used, and in practice its percentage amount should always be regular or within certain limits.

The distinguishing feature of aluminous cake when compared with other aluminous compounds used by paper makers for sizing, lies in the fact that it always contains

a certain percentage of silica and undecomposed clay which are insoluble in water, but serve as loading material when it is added in the crude solid state to the pulp in the beater engine. In the manufacture of common news- and cheap printing-papers, when loading substances are used, this insoluble matter in the aluminous cake remains with the fibre, and appears in the finished sheet of paper, representing so much ash.

By virtue of this fact, the insoluble matter possesses a value of its own, corresponding to its equivalent in weight and the value of china clay, which, as is well known, is the most commonly used loading material in the paper trade.

Aluminous cakes should be free from grit and dirt of any kind, and it is usually added directly to the pulp in the beater engine, no care on the part of the paper maker being taken to free it from these impurities before use. The insoluble matter consists of varying quantities of silica and undecomposed clay. Although these are in a fine state of division, they do not possess the same properties as china clay. Neither of them feel so soft or soapy when rubbed between the fingers. The silica is in a state of very fine powder, but nevertheless does not possess the power of communicating that body and surface frequently required in finished paper, and any lack of surface on papers sized with aluminous cake is very likely due to the presence of this ingredient. The requirements of the printer demand that paper, when used on the high-speed printing machines of the present day, will not yield any dust, and as it is difficult to fix silica within the fibre when in a very fine state of division on soft size paper, especially when starch cannot be or is not used, the probability is that this silica, and indeed the undecomposed clay as well, is thrown off on unwinding the reel as it enters the printing machine and causes the trouble referred to, besides stopping up the type. A common basis of comparison of the amounts of ferrie sulphate in aluminous cakes offered in the market, is generally adopted. If the amount of sulphate of iron be calculated on 100 parts of anhydrous sulphate of alumina in each of the analyses of the foregoing samples, the relative quantities of iron salt are strictly comparable. Anhydrous sulphate of alumina is really the useful ingredient to paper makers in the aluminous cakes they buy, and hence to compare one sample with another, all impurities should be calculated on, say, 100 parts of sulphate of alumina. In the case of the impurity, viz. ferrie sulphate, in analysis "A" we have thus, 1.076 parts, and in "B" 1.269 parts on 100 of anhydrous sulphate of alumina. This example may be extended of course to comparison with the other impurities.—W. S.

PATENTS.

Bleaching Paper Pulp by Electricity. E. H. M. Andreoli, Brixton. Eng. Pat. 8161, June 4, 1888. 6d.

THIS process relates to the bleaching of paper pulp, &c. by means of an electrolysed solution of common salt or sea water. The inventor claims in addition: The construction of anodes and cathodes by fusing, casting, reducing, and peroxidising chloride of lead alone (for cathodes) and in combination with other metallic salts, such as chloride of manganese (for anodes); the use of an alternating current; the treatment of paper pulp in bleaching tanks where the electrolyte, raised to its proper degree of bleaching power by the action of oxygen or ozone in its nascent state, in combination with chlorine and hydrogen, circulates and is maintained at the required chlorometric standard by the influx of freshly electrolysed solution to replace the corresponding quantity of exhausted electrolyte which flows out of the tank by a pipe, and also of a large peroxidised anode and a spongy lead or carbon cathode through which an electric current passes. He also claims the whole process for bleaching paper pulp by the action of hypochlorite of sodium electrolytically generated by means of plates made of a cheap conductive material not easily attacked and corroded by chlorine or oxygen, such as wood charcoal, either for both cathode and anode, but specifically for anode, in the electrolytic tank where chlorine is generated

and combines with hydrogen and oxygen in a more or less active state. It is advisable to heat the liquid to be electrolysed to 60° C.—E. J. B.

Improvements in Machinery or Apparatus for Coating Paper or other Fabric with Glue, Gum, Paste, or other Fluid or Semi-fluid Material. G. J. Feldon, Lambeth. Eng. Pat. 18,066, December 11, 1888. 8d.

A CYLINDER is fixed upon a shaft mounted so as to revolve in a bath of the coating material, so that the underside of the periphery of the cylinder is immersed in the bath. The fibre to be coated is drawn across the cylinder from between nipping rollers covered with india-rubber.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Myrtle Oil and Myrtol. E. Jahns. Arch. der Pharm. 27 [3], 174.

THIS oil as used medicinally begins to boil at 160° and about 80 per cent. distilled over up to 240° C. The residue consisted of high-boiling terpenes partly resinised and partly polymerised. From the portion boiling between 160° to 240° C., by repeated fractional distillation the following constituents were separated:—

A Terpene, $C_{10}H_{16}$, boiling between 158° and 160°, and having a specific rotation $[\alpha]_D^{20} = +36.8^\circ$. Its properties led the author to believe it to be right-handed *Pinene*.

Cineol, $C_{10}H_{18}O$, which purified by Wallach's method, boiled constantly at 176°.

A Camphor, probably of the formula $C_{10}H_{16}O$, in small quantity, boiling at 195° to 200° C. The therapeutic value of the *Myrtle Oil* is to be traced to the amount of cineol present in it, the latter substance being identical with eucalyptol and eucalyptol.—W. S.

Some New Compounds of the Quinine Alkaloids. J. Hesse. Pharm. Zeit. 1889, 191.

THE compound of phenol with some salts of the quinine alkaloids of left-handed polarisation have long been known and are much used as febrifuges, as e.g., quinine phenol sulphate, $(C_{20}H_{21}N_3O_2)_2 \cdot SO_3 \cdot C_6H_5O + 2 H_2O$. The author has recently prepared a new compound of phenol with quinine bisulphate. If carbonic acid be added in equivalent proportion to a hot aqueous solution of quinine bisulphate, on cooling at first an oily mass separates out, above which delicate white needles are gradually formed, of the composition $C_{20}H_{21}N_3O_2 \cdot SO_3 \cdot C_6H_5O + 3 H_2O$. This compound is very unstable. If it be dissolved in hot water, on cooling the first-named normal salt crystallises out. Quite in accordance with this is the behaviour of the acid Quinine resoreinol sulphate, the acid Quinine quinol sulphate, the acid Quinine pyrogallol sulphate, and the acid Cinchonidine pyrogallol sulphate, for one and all they separate out the normal salts when the attempt is made to recrystallise them from hot water. The author further prepared and describes the normal Quinine oreinol sulphate, Quinine catechol sulphate, Cinchonidine quinol sulphate, as well as the Quinine resoreinol, Quinine catechol, and Quinine pyrogallol hydrochlorides. They are beautifully crystallised compounds and some of them excellent febrifuges.—W. S.

Mercury Benzoate. E. Lieventhal. Pharm. Zeit. Russl. 28, 310.

ONE hundred and twenty-five parts of mercuric oxide are dissolved in 250 parts of nitric acid (1.20 sp. gr.), the solution diluted with 4,000 parts of water and filtered; to this a solution of 188 parts of sodium benzoate in 4,000 parts of water is gradually added with agitation. The voluminous precipitate of mercuric benzoate obtained, after washing, pressing and drying, forms a light, white powder, soluble with difficulty in ether, alcohol, chloroform and water.—O. H.

Macassar Oil. L. v. Itallie. Apoth. Zeit. 1889, 4, 506.

Schleichera trijuga is one of the *Sapindaceæ* and bears red-brown seeds averaging 0.5 grm. in weight; these contain about 36 per cent. of a buttery fat which is "Macassar oil." It has a specific gravity of .924 at 15° C., melts at 28° C., has an iodine number of 53, a saponification equivalent of 219 (1 grm. requires 230 mgm. of potash for saponification), contains 91 per cent. of insoluble fatty acids and 6.3 per cent. of glycerol. The fatty acids present include acetic, butyric, lauric, arachidic and oleic acids.

—B. B.

Macassar Oil. K. Thümmel. Apoth. Zeit. 1889, 4, 518.

A SAMPLE examined by the author had a melting point of 21°—22° C. instead of 28° C. given by Itallie (see preceding abstract). The presence of hydrocyanic acid was detected and 0.047 per cent. obtained by steam distillation. Benzaldehyde was recognised in the distillate by its transformation into benzoic acid by the action of potassium permanganate. These substances might have owed their origin to sophistication with bitter almond oil; an examination of the seeds would settle this point.—B. B.

Compounds of Mercury with Phenols. E. Merck. Apoth. Zeit. 1889, 4, 651.

Mercury phenate, Hydrargyrum phenolicum, is obtained by precipitating corrosive sublimate with sodium phenate. According to the conditions of precipitation a more or less basic salt is obtained which is used for injections in the treatment of syphilis.

Mercury thymylate is obtained by precipitating mercuric nitrate with sodium thymylate and forms a greenish-violet precipitate of the formula $C_{10}H_{13}HgOH$.—E. E. B.

Distilled Perfumes and Essential Oils. Report by Consul Mason, United States Consulate, Marseilles, 602.

THE process of distillation varies but slightly for all varieties of lavender, and the same apparatus is often used successively for each kind of plant as its season of flowering and harvest arrives. The necessary machinery includes as its principal feature a copper alembic, usually about 6 ft. in height by 4 in. diameter, the beak of which is carried over and terminates in a spiral coil immersed in cold water. Each alembic has, near the top, an opening closed by a man-head, secured by bolts as in ordinary steam machinery. Through this opening the mass of fresh plants is packed into the interior until it is completely filled. Near the bottom of the alembic another similar opening is provided through which the spent material may be withdrawn with a pronged hook like a manure fork with curved tines. The bottom is covered with a perforated copper diaphragm, under which lies a flat coil of pipe, likewise perforated, through which steam is introduced from a boiler in which a pressure of from 5 to 7 atmospheres is maintained. The alembic being thus charged with raw material—either freshly gathered or dry—and the man-heads closed, the steam is turned on and forces its way upward through the mass, absorbing and carrying the perfume over into the submerged coil, where the oil condenses and trickles out with the distilled water, upon which it floats by reason of

lighter gravity. In about three hours the perfume is exhausted, when the alembic is emptied and recharged. Three hundred pounds of dried lavender plants, or 220 lb. of *Aspic*, are required to produce 1 lb. of essential oil.

There are two species of the absinthe plant—the large and small—which are used respectively in the manufacture of absinthe liqueurs and vermouth. In manufacturing the liqueur the upper leaves and twigs of the plant are macerated with hyssop, calamus, citronelle, anise, fennel, diadane, and other vegetable substances. The decoction thus obtained is distilled, and the product treated with alcohol, sugar, and various colouring matters.—A. J. S.

Report on New Drugs and Fine Chemicals. Merck's Bull. 2 [6].

Chromic Acid.—This acid has been known as an escharotic in the nasal and pharyngeal cavities as far back as 1885. Danger had hitherto been found in the use of this stringent means of topical causticisation, of cauterising the adjacent healthy parts. This danger has been traced to the usual presence of sulphuric acid in the preparations offered. This sulphuric acid makes the chromic acid (anhydride) deliquescent and causes it therefore to run upon adjacent parts and so spread the action too far. If but traces of sulphuric acid are present the action may be injurious, and hence the Prussian War Department ordains that only chemically pure chromic acid may be used in the treatment of foot-sweat among the troops.

Pyrodiene or Acetyl-phenyl-hydrazine.—Guttmann's researches (Berliner Med. Ges. May 1, 1889) fully confirm the results of Dreschfeld of Manchester.

Antiseptic (Brominated Antifebrine or Parabromophenyl Acetamide), $C_6H_4(Br)NH.COCH_3$, is devoid of smell or taste. It crystallises in small, pearly prisms, melting at 164.5° C. It is insoluble in cold, with difficulty in hot water, only slightly in glycerol, but easily in alcohol or ether. A one per cent. alcoholic solution may be treated with twice its volume of water or thrice its volume of glycerol, without turbidity ensuing.

Evalgine (Methylphenylglucetamide or Methylated Antifebrine), $C_6H_5N(CH_3)CO.CH_2$ —It appears in the form of white plates or fine white needles, melting at 101° C. Compare this Journal, 1889, 412 and 567.

Methacetine (Orymethyated Antifebrine or Para-acetamidine), $C_6H_4(OCH_3)NH.COCH_3$.

As might have been suspected, from its chemical constitution, so analogous to that of Phenacetine, it appears that Methacetine has developed physiological properties quite similar to those of the former substance. Its action is antithermic, without untoward accessory symptoms, though frequently, according to Mahner, heavy perspirations ensue. The antiseptic properties of Methacetine are proved by the fact that a 1 per cent. solution arrests the decomposition of milk, and prevents the ammoniacal fermentation of urine.

Chloral Urethane, CC_l3.CH(OH)NH.CO.OC₂H₅ is obtained by the union of 1 mol. of chloral (not the hydrate) to 1 mol. of urethane, thus:—

It is a crystalline mass, insoluble in cold water, and decomposed by boiling water into its two components. Alcohol and ether dissolve it readily, and water separates it from these solutions. Its melting point is about 103° C.; it attains this point only, however, after partially decomposing from 100° C. upwards. Chloral-urethane was first investigated as to its therapeutic properties by Hübner and Sticker (*Deutsche med. Wochenschr* 1886 [14], 236), and compared with ethylidene-urethane and methyl-urethane. The last two compounds were found to be entirely inert in doses of 1

to 4 grms., whilst chloral-urethane produced hypnotic effects like ethyl-urethane, although in a less certain and persistent degree. Mairet and Combemale (*Mondpellier med.*, 1886, 149) concluded that the toxic effect outweighed the hypnotic in prominence and importance of symptoms. The sleep induced was always attended with paralysis of the hinder parts in the case of animals.

Nicotine Bitartrate (Acid tartrate).—The manufacturing method for preparing this salt was invented by Dr. Dreser, of Strasburg. It is a beautifully crystalline substance, and perfectly stable, whilst on the other hand all the remaining known simple salts of nicotine are very difficult to crystallise, and hence the strengths of their solutions become variable and unreliable. Also the solutions of the free alkaloid have the tendency to resinify, thicken, and darken, and to become therapeutically unavailable. The *Bitartrate* (Dreser) crystallises in fine white tufts of needles, and is very readily soluble in water. Its composition, on analysis, shows the proportions $C_{10}H_{11}N_2$ (nicotine) = 32.53 per cent.; 2 $(C_4H_4O_6)$ tartaric acid = 60.51 per cent., and 2 H_2O = 7.34 per cent. The physiological experiments (*Archiv. der Pharm.* 1889, 269) showed that the well known specific effects of the pure alkaloid are all produced likewise by this salt, and in like degree.—W. S.

Synthesis of Active Coniine. A. Ladenburg. *Ber.* 22, 1403—1405.

SCHORLEMMER ("Rise and Development of Organic Chemistry") has stated that the complete synthesis of active coniine has not yet been accomplished, but the author has previously shown that the alkaloid in question can be obtained from its elements.

Acetic acid can be prepared synthetically, and from it acetone, isopropyl alcohol, and glycerin can be successively obtained. Glycerin can be converted first into bromallyl, and then into trimethylene bromide, and from the latter piperidine and finally pyridine can be produced. α -Picoline can be obtained from pyridine (Ladenburg and Lange, *Ann.* 247, 5), and can be converted into coniine (Ladenburg, *Ann.* 247, 80). (This Journal, 1887, 224.)

The dextro-tartaric acid, which is necessary to the production of the active base, can also be prepared from its elements.—F. S. K.

Acetyl Derivatives of Quinic Acid. E. Erwig and W. Koenigs. *Ber.* 22, 1457—1464.

Triacetylquinide—

is obtained when quinic acid (10 grms.) is boiled with acetic anhydride (70 cc.). After distilling most of the acetic anhydride and acetic acid the residue is repeatedly evaporated with absolute alcohol on the water-bath, washed with cold ether to remove resinous impurities, and recrystallised several times from boiling alcohol with addition of animal charcoal. The yield of pure substance is 8 grms. Triacetylquinide melts at 132°, is almost insoluble in cold dilute sodium carbonate and only sparingly soluble in cold water and cold alcohol, but readily in the boiling solvents. The conversion of quinic acid into the crystalline and easily-purified triacetylquinide can be employed as a most characteristic reaction for the identification of small quantities of the acid.

When triacetylquinide or quinic acid is heated with acetic anhydride at 240° an isomeric triacetylquinide (isotriacetylquinide) melting at 139° is formed. The yield of pure substance, isolated as described above, is 50 per cent. of the quinic acid employed. Isotriacetylquinide is almost insoluble in cold dilute sodium carbonate, and is similar to triacetylquinide in its behaviour towards solvents.

When quinic acid is boiled with acetic anhydride and sodium acetate the principal product is the triacetyl derivative, melting at 132°, but when a small quantity of anhydrous zinc chloride is employed instead of sodium acetate, tetracetylquinic acid is formed in almost theoretical quantities.

Tetracetylquinic Acid. $(OC_2H_3O)_4 \cdot C_6H_7 \cdot COOH$, melts at about 130°—136°, and is readily soluble in hot water and sodium carbonate, but only sparingly in carbon bisulphide, and almost insoluble in light petroleum.

When quinic acid is heated with acetic anhydride at 170° a mixture of triacetylquinide and tetracetylquinic acid is obtained.

The two triacetylquinides are probably γ - or δ -lactones of quinic acid. Quinic acid seems to contain two OH-groups in the γ - and δ -position to the carboxyl-group for, when an aqueous solution is evaporated with bromine, protocatechuic acid is formed. The formation of meta-chlorobenzoic chloride by heating quinic acid with phosphorus pentachloride also indicates the presence of a γ -OH-group. A third OH-group seems to be in the α -position, as quinic acid, like other α -hydroxycarboxylic acids, evolves carbonic oxide and yields hydroquinonedisulphonic acid when treated with concentrated sulphuric acid.—F. S. K.

Lapacholic Acid and its Derivatives. S. C. Hooker and W. H. Greene. *Ber.* 22, 1723—1727.

The authors have obtained lapacholic acid from a South African wood called *Bethabana*. The substance is identical with that got by Sievert from the lapacho-wood of South America and examined by Paterno. Amongst the derivatives of lapacholic acid obtained by the latter is a body formed by the action of concentrated sulphuric acid, which crystallises in red needles, and to which the name lapachon was given. Paterno assigned the formula $C_{15}H_{11}O_3$ to the acid, regarding it as hydroxyamylene naphthoquinone—

and looked upon lapachon as consisting of two molecules of the acid united by the oxygen atoms of the ketone groups, and as having the formula $C_{30}H_{22}O_6$. The authors have examined this latter body further and find that it possesses all the characteristic properties of a quinone; also its molecular formula as determined by Raoult's method is $C_{15}H_{11}O_3$, and not the double of this. To account for this change it is assumed that lapacholic acid when treated with strong acid first takes up a molecule of water to form an intermediate compound, which is then acted upon by the acid with the elimination of water and the formation of lapachon, which is regarded as a derivative of naphthofurfuran. The following equation expresses the change, using Paterno's formula for the acid:—

Lapachon is not affected by treatment with alkalis or with alkaline carbonates in the cold, but it dissolves in the former on heating, and from this solution acetic acid separates a red oil which solidifies to a yellow crystalline mass melting at 125° C. when pure, and which gave on analysis numbers agreeing with the formula $C_{15}H_{10}O_3$. This is regarded as hydroxyhydrolapacholic acid, the intermediate product in the above reaction. The barium and silver salts of this acid are characteristic.

Other derivatives of lapacholic acid obtained by Paterno are regarded as derived from naphthofurfuran.—C. A. K.

Pseudo-ephedrine. A. Ladenburg and C. Oelschlägel.
Ber. 22, 1823—1827.

NAGAI extracted an alkaloid *Ephedrine* from the plant *Ephedra vulgaris*, the physiological properties of which have been examined, but there is very little known of its chemical nature. From the same genus *Ephedra*, Merck has isolated a second alkaloid by extracting the leaves with alcohol, and to this the name of pseudo-ephedrine is given. This substance has been examined by the authors. It is obtained in the pure form as the hydrochloride by treating the alcoholic extract of the leaves with ammonia, shaking out with chloroform, and after distilling off the latter converting the residue into the hydrochloride and recrystallising this repeatedly from ether-alcohol. This salt is readily soluble in water and alcohol; it melts at 176° and has the formula $C_{10}H_{15}NO \cdot HCl$. The free alkaloid is a crystalline body possessing a slight and very pleasant smell. It dissolves readily in alcohol and ether, slightly in hot water, and melts at 114°—115°. An analysis and a molecular weight determination by Raoult's method agree with the formula $C_{10}H_{15}NO$. Of the salts the picrate, periodide, and the double salts with platinum chloride, cadmium iodide and bismuth iodide are not crystallisable. The gold double salt forms crystalline needles; the hydrobromide melts at 174°—175°, the hydriodide at 165°, and both crystallise well.

Treated with potassium nitrite the hydrochloride yields a nitroso-compound, $C_{10}H_{13}N_2O_2$, showing the base to be a secondary amine. On oxidation with potassium permanganate pseudo-ephedrine yields only benzoic acid; the hydrochloride heated with strong hydrochloric acid in a sealed tube yields a product boiling at 130°—150°, and which on oxidation also yields benzoic acid. At the same time an amine which, from the analysis of its platinum double salt, appears to consist of methylamine together with an amine richer in carbon, results. From these facts the authors regard the following constitutional formula for pseudo-ephedrine as probable:—

The product got by treatment with hydrochloric acid would most likely be a mixture of benzyl-alcohol and phenyl ethyl carbinol, from which benzoic acid would result on oxidation. That there are two replaceable hydrogen atoms is proved by treatment with benzoyl chloride when a crystalline body, $C_{10}H_{13}NO(C_6H_5 \cdot CO)_2$, is obtained.—C. A. K.

Betaine and Choline from the Seeds of Vicia Sativa.
E. Schulze. Ber. 22, 1827—1829.

BETAINE and choline can be extracted from the vetch (*Vicia sativa*) by treating the finely powdered seeds with 90—95 per cent. alcohol, distilling off the latter and then adding tannic acid and lead acetate to the turbid aqueous solution of the residue. After removing the lead in the filtrate by sulphuretted hydrogen and evaporating down the solution obtained after filtering off the lead sulphide, a syrup remains, and this on being extracted with first absolute and then 95 per cent. alcohol after acidifying with hydrochloric acid, yields an extract from which the cholin and betan are precipitated as double chlorides on the addition of an alcoholic solution of mercuric chloride. By decomposing the double salts with sulphuretted hydrogen and filtering off the sulphide of mercury, the chlorides of betaine and of cholin remain in solution, and can be separated by fractional crystallisation from cold absolute alcohol.

11—12 grms. of betaine and 3—3½ grms. of choline were extracted from 20 kilos. of the seeds. Some betaine remains in the residue after extracting the above-mentioned syrup with alcohol; this residue also contains the nitrogenous substance vicin previously isolated from vetch seeds by Ritthausen (J. Prakt. Chem. [2], 24, 202).

It was incidentally remarked by the author that the double platinum chloride of choline crystallises in regular octahedra as well as in prisms.—C. A. K.

Advantage of Santoninoxime over Santonin. F. Coppola.
Rep. de Pharm. 1889, 45, 257.

SANTONIN often produces symptoms of poisoning owing to the large amount of lactic acid formed in the bowels when it is used as a vermifuge, the acid effecting the solution of the santonin. Cannizaro has obtained crystallised santoninoxime by the action of hydroxylamine hydrochloride on santonin in an alkaline solution. This is not poisonous, and is just as efficacious as santonin when given in doses two to three times as large.—E. E. B.

Growth of Quinine in Java. Nederl. Tijdschr. v. Pharm. Chem. en Toxicol. 1889, 1, 152.

THE yield in 1888 was 700,000 lb., of which 603,845 lb. were sent to Batavia. The yield for 1889 is estimated at 900,000 lb. the small yield of 1888 being attributed to prolonged drought.—E. E. B.

Crude Cocaine.

IN the current number of *Ephemeris* it is stated that it is highly probable that the importation of coca leaves into the States and Europe for the manufacture of cocaine is nearly at an end. For more than a year past crude cocaine has been sent from Peru to the States and Europe in rapidly increasing quantities, and of better and better quality than in 1885, when it was first made. During 1888 the quantities exported from Peru became very large, and the quality reached 90 to 96 per cent., and occasionally even 98 per cent. There are now at least four manufacturers in Peru, and the chief market for their products is Hamburg, and, curiously enough, their products can be had better, cheaper, and in a shorter time from Hamburg than from Peru. Besides this, there is a combination of the makers now to keep up the price and to confine the sales to Hamburg. Some idea of the very large quantities produced may be had from the circumstance that one maker has a single contract with a European house for 70 kilogs., or about 154 lb. per month. Another curious circumstance connected with this young industry is that one of the largest and most successful makers is by trade, and was by occupation, a bricklayer when Dr. Squibb's processes were published, and simply took them up as a better and more promising trade for making money. The advantages of exporting the crude alkaloid rather than the coca leaves are many and important. As cocaine is transported in the treasure chests of the steamers the difference in freight is about as ½ lb. to 100 lb. of the leaves. But a much more important economy is shown by a comparison of the yield of alkaloid, by the same process from the same leaves, as worked here and in Peru, the yield there being 13 to 15 per cent. greater. This is owing to the fact that the leaves in transport undergo deterioration. Crude cocaine comes either in granular powder or in fragments of press cake of all sizes and forms up to an inch or two in superficial area, and from a quarter of an inch to an inch in thickness. The general colour is a dull, creamy-white, but is rarely quite uniform throughout any package, varying from a dirty or brownish white to very nearly white. But in this matter of colour it is constantly improving. The fragments vary more in consistence than in colour. A large proportion are hard, compact, and slightly horny when cut or scraped, while others are softer, more porous and chalk-like, and easily cut or scraped, the general density being lighter than the softest, lightest chalk. In Hamburg crude cocaine is nearly all sold upon assays which have generally been in fair accord with each other, and the New York Custom house has generally accepted them in adjusting the duty.—*Chemist and Druggist.*

Discovery of Podophyllin in the Himalayas.

Allen's *Indian Mail* for the 12th August last, quoting from a Lahore paper with reference to a discovery of podophyllin in the Himalaya, says:—

“Dr. George Watt has made a discovery which seems likely to provide the hill tribes of the higher Himalaya

with a lucrative trade, and to supply the medical profession with an abundance of podophyllin, a drug which, as many Anglo-Indians have good reason to know, is a valuable specific in disorders of the liver. Hitherto America has enjoyed a monopoly of the podophyllin plant (*Podophyllum peltatum*), but the researches of Dr. Watt and the analysis by Dr. Hooper, quinologist to the Madras Government, demonstrate that the Himalayan variety (*Podophyllum emodi*) yield three times as much of the valuable resin as the American root, and that it possesses the same medicinal properties. This valuable plant grows wild in the higher, rich, and shady temperate forests from Sikkim to Simla, Kashmir, Hazara Tibet, the Kuram Valley, and Afghanistan. It is fairly plentiful on the northern forest-clad slope of the familiar Shalai hill, seen from Simla; on the almost equally well-known Nagkanda hill and in the Chumba State there are many mixed forests with their glades almost exclusively covered with this prony-rose-like herb. In his notes on the subject Dr. Watt remarks that it is surprising that the natives of India, who have discovered so many drugs, should have failed to detect the properties of the podophyllum root."

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Ammonia in the Gelatin Emulsion. Photogr. Wochenbl. 1889, 15, 132.

In preparing an emulsion by the cold process with ammonia, Belitzki recommends that most of the ammonia be neutralised with sulphuric acid towards the end of the process. An excess of acid must be avoided, as the least trace of free acid diminishes the sensitiveness of the emulsion. If some aurin-collodion be placed on a glass plate and the emulsion added to it, a rose-red colour will be produced if the emulsion is alkaline.—E. E. B.

Preparation of Plates Sensitive to Colour. E. Obernetter. Photogr. Wochenbl. 1889, 15, 133.

The emulsion is made with little gelatin and poured over the plates thin. It is not advisable to add the colouring material to the emulsion at once. If a bath be used for dipping the coloured plates, it has the disadvantage of becoming weaker after the immersion of every plate, so it is preferable to pour the colouring material in an extremely dilute solution over each plate separately, after washing it thoroughly. A good recipe for the colour solution is:—50 parts erythrosin solution (1:1,000), 50 silver nitrate solution (1:1,000), 3 ammonia. The plates may be exposed with or without a yellow screen, but in the former case more than twice as long an exposure is necessary. For developing, an alkaline solution of pyrogallol acid or a hydroquinone solution is used.—E. E. B.

Use of Sodium Sulphite in the Fixing-Bath. Photogr. Archiv. 1889, 30, 161.

When a gelatin dry plate, which has been developed by means of pyrogallol acid, is placed in the fixing-bath of sodium hyposulphite, unless the pyrogallol acid solution has been perfectly removed by washing, the plate will become yellow. To obviate this, William Bell recommends the addition of sodium sulphite to the sodium hyposulphite (proportion 1:5). Negatives fixed by this solution have the tone and character of collodion negatives prepared by the wet process, and the bath can be used much longer.

—E. E. B.

Citric Acid in the Hydroquinone Developer. Thomas. Photogr. Archiv. 1889, 30, 162.

The developer consists of two solutions, which are mixed in equal volumes immediately before use. No. 1 consists of 5 parts hydroquinone, 32 sodium sulphite, 2 citric acid, and 1 potassium bromide in 128 parts of water. No. 2 consists of 5 parts caustic soda in 128 of water. This is eight times as powerful as the ordinary pyrogallol acid developer.—E. E. B.

Theory of the Hydroquinone Developer. Phot. Rundschau. 1889, 3, 119.

HYDROQUINONE, $C_6H_6O_2$, is prepared by the action of sulphurous acid on quinone, $C_{10}H_6O_4$. By the action of the former on exposed silver bromide two atoms of hydrogen unite with the bromine liberated and silver is set free, which forms the picture—

Quinone is thus formed again, and the hydrobromic acid combines with the alkali which is necessarily always present in the developer. The alkaline bromide retards development, and on this account old solutions always develop more slowly. The sulphurous acid in the sodium sulphite is supposed to prevent or diminish the rendering of the gelatin brown by the action of the quinone.—E. E. B.

Intensifying by Means of Hydroquinone. Phot. Rundschau, 1889, 3, 194.

If a gelatin negative has been treated with mercuric chloride to intensify it until it has become quite white, instead of then treating it as usual with ammonia it is advised by Dr. Mallmann to wash the plate quite free from any adhering mercuric chloride, and then pour over it a solution of hydroquinone containing sodium sulphite or dip the plate into this solution. The result is an intense negative of a bluish-black tone.—E. E. B.

PATENT.

Improvements in Photometers for Measuring the Intensity of Light in Photographic Camera. J. Decoudun, Paris, France. Eng. Pat. 11,578, August 10, 1888. 8d.

By means of this apparatus the intensity of the light focussed on the screen of the camera, and from that the time of exposure, may be determined. The photometer consists of a series of translucent sectors of a rotary disc, or, as in a modification, of a stationary disc divided into squares or spaces of different degrees of translucency, each bearing a letter or other sign indicating the period of exposure. In the former case the disc is rotated to bring "the gradually darkening luminous points" opposite a lens and eye-piece, while the stationary disc is mounted in a tube also provided with eye-piece and lens. When placed against the focussing screen and viewed through the lens, the letter which is least visible indicates the time of exposure.—O. H.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENTS.

Improvements in Explosive Compounds. A. V. Newton, London, From A. Nobel, Paris. Eng. Pat. 10,722, July 24, 1888. 4d.

This invention relates to the manufacture of an explosive consisting of nitrate of ammonia and picrate of ammonia in the proportion of three parts of the former to one part of the latter.

Gum arabic, dextrin, or an analogous substance is added in the proportion of about $\frac{1}{2}$ per cent. of the material, with a view of hardening it.—C. N. H.

Improvements in Protecting and Preserving Explosives.
C. Lamm, Stockholm, Sweden. Eng. Pat. 11,751,
August 15, 1888. 6d.

THE object of this invention is to protect and preserve explosives which contain hygroscopic salts.

In carrying out the invention, carnauba or other palm wax is employed mixed with Japan wax, naphthalene, paraffin, &c. as a waterproof coating for the explosive when made up into blocks or cartridges.—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

On a New Hydrometer. W. Láska. Zeits. f. Instrumentenkunde, 9, 176.

IN consequence of capillary action, measurement by the hydrometer is not certain.

If p be the weight, α capillary constant, ω the angle of contact (Randwinkel), r the radius of the hydrometer, v the volume immersed, d the density of the liquid, u the volume of the instrument in the air, and δ the specific gravity of the air, then—

$$p + 2\pi r \alpha \cos \omega = v d + u \delta$$

or when $u \delta$ is very small and can be neglected—

$$p + 2\pi r \alpha \cos \omega = v d.$$

If, now, p be largely increased, while α and r remain the same, then—

$$p_1 + 2\pi r \alpha \cos \omega = v_1 d$$

$$p_1 - p = (v_1 - v) d; \text{ or } d = \frac{p_1 - p}{v_1 - v}.$$

By means of the instrument shown in the figure which is based on this formula, the influence of capillary action can be avoided. To the upper part of A the tube B is fused. Its use is obvious. The instrument is placed in the liquid and the height read off; a known weight of mercury is then run into B and the height again read off (best by a cathetometer). The difference of height in mm. in weight of mercury in milligrams represents the specific gravity of the liquid.—O. H.

Arsenic in Glycerin (Glycerol). L. Siebold. Pharm. Conference, Newcastle-on-Tyne. Pharm. J. 1889, 205.

THE author has investigated colourless and odourless samples of glycerin sold for toilet and pharmaceutical purposes (this Journal, 1889, 639—640). The majority of the samples tested were found to contain arsenious acid varying in proportion from 1 part in 4,000 parts to 1 part

in 6,000. A few samples exceeded this proportion, and one contained as much as 1 part in 2,500. Some samples free from arsenic were traced all to one process of manufacture, described as being that by which, as a rule, glycerin used for dispensing purposes is understood to be used. The process followed in testing, which was demonstrated by the author, was a modification of one recently recommended by Vulpinus and Flückiger, which depends upon the action of the gas given off by a mixture of the glycerin with zinc and very dilute hydrochloric acid in a test tube upon a paper cap that has been touched with a drop of a solution of mercuric chloride, a yellow spot being the result of the presence of minute traces of arsenic. A further observation by the author was consistent with arsenic being sometimes introduced into glycerin from the glass of the containing bottle, and it is proposed to further investigate this point; but there was a general agreement among the speakers that such quantities of arsenic as those found in some cases were more probably introduced during the manufacture.—W. S.

Solidification of Nitrogen Trichloride. F. Birhans. Compt. Rend. 109, 63.

NITRIC oxide and oxygen in the proportions of 6—8 volumes of the former to 1 volume of the latter were passed through a U-tube cooled to 54°. The large excess of nitric oxide is necessary to prevent the formation of any nitrogen peroxide. The gases must be well dried previously by passing over pumice stone moistened with sulphuric acid, dry baryta, and lime. The blue liquid which collects in the U-tube may be solidified by a mixture of methyl-chloride and carbonic acid with snow, that is to say, at a temperature of -82°C . —A. R.

Wiborgh's Volumetric Process for the Estimation of Sulphur. A. Vosmaer. Chem. Zeit. 13, 695.

THE author substitutes twill for white calico for the collection of the cadmium sulphide, but otherwise performs the analysis as described by Wiborgh. The standard iron is prepared by fusing cast iron with sulphide of iron. Half a gram of a sample is ample for analysis.—E. E. B.

Volumetric Estimation of Sodium Carbonate in the Presence of Sodium Hydrate in Commercial Caustic Soda. H. Goebel. Chem. Zeit. 13, 696.

A DROP of an alcoholic solution of phenol phthalein is added to the cold solution and standard acid added till the colour is destroyed; a drop of Porrier's blue (C. L. B.) is added and then more acid till the solution becomes purple (the colour of an ammoniacal solution of copper). The difference between the first and second titration corresponds to half the sodium carbonate present.—E. E. B.

On the Absorption of Atmospheric Gases by Water.
O. Pettersson and K. Söndén. Ber. 22, 1439—1446.

THE authors have determined the quantity of dissolved gases in water from the Baltic and in the town's water of Stockholm. The results obtained differed so materially from the coefficients of absorption calculated by Bunsen, that it was found advisable to repeat Bunsen's experiments with pure water. The apparatus used is shown in the figure. The side tube of flask A is Y-shaped. One limb is in connexion with the reservoir C, the other with the vessel F, which contains mercury. The caoutchouc tubing between F and D is surrounded by a coil of copper wire. Before introducing the water, F is entirely filled with mercury and the stopcock y is closed. A and B having been filled with water, x is opened and y closed. All the air is now expelled by vigorous boiling of the water in A and of that portion which has passed into F. The operation takes half an hour. In one experiment N and O may be determined, but not CO_2 .

Sulphuric acid should not be added to the water, otherwise mercurous salt is liable to be formed at the cost of the oxygen expelled. After removing CO_2 with caustic soda, oxygen is absorbed by a solution of pyrogallic acid. The great advantage of this apparatus is that constant and almost perfectly accurate results are obtained with it, as the water to be analysed is shut off from contact with the outer air by mercury. Boiling may be continued indefinitely. It is of the greatest importance that the water used should be kept as nearly as possible at the same temperature while it

stress should be laid upon the determination of these gases in water analyses than has hitherto been done. Thus, to find a water abnormally deficient in oxygen, would point to the influence of animal or vegetable life. Attention is drawn to the fact that spring water often contains marsh gas dissolved along with nitrogen. These two gases are obtained together during analysis, and if the volume be larger than is noted down for nitrogen at the given temperature in the above table, the mixture must be further analysed by combustion with oxygen. Thus the authors have found as much as .7 cc. CH_4 per litre in a spring water. Sometimes however there is really an excess of nitrogen, due to the high air-pressure in the regulators of the waterworks, which leads to supersaturation so far as nitrogen is concerned, but not in regard to oxygen.

The town's water was richest in oxygen in September (about 3 cc. over the average); the lowest amount was found in February (about $1\frac{1}{2}$ cc. under the average). The variations in the amount of carbonic acid were just in the reverse order. The maximum of CO_2 was in September (29 cc.) the minimum in March (18 cc.), which facts are probably due to more favourable conditions for oxidation at the summer's heat.—A. R.

The Solubility of Oxygen in Water. L. W. Winkler. Ber. 22, 1764—1771.

In a former paper (Ber. 21, 2843) the author showed that Bunsen's determination of the absorption coefficients of oxygen, nitrogen, and air required correction. The present paper is devoted to the more accurate determination of the solubility of oxygen in water.

The oxygen was estimated in water saturated with air at different temperatures (0° — 30° C.) by the iodometric method described by the author in a former communication, and from these values the absorption coefficients were calculated.

The analytical method was also improved, regard being had to the fact that under ordinary conditions the reagents themselves contained oxygen in solution. This source of error was overcome by employing almost saturated solutions of the reagents, viz., 80 grms. MnCl_2 , 4 H_2O dissolved and made up to 100 cc. The caustic soda and iodide of potassium were about 12 times normal strength.

The hydrochloric acid was freed from oxygen by passing carbonic acid through it and then boiling, whereby the carbonic acid was expelled, carrying the oxygen along with it. This process was repeated several times, and the author lays special stress on the necessity of boiling the acid to get rid of the last traces of oxygen. The following apparatus was used: (Fig. 1).

Fig. 1.

is being saturated with air. The authors were only satisfied when no change greater than 1 C. was observable in 5—6 hours.

The following figures were obtained, corresponding to cc. in 1 litre of water, saturated with air, by frequently pouring from one vessel into another:—

Tem- perature of the Water.	Found.			Calculated for Absorption at 760 mm. Pressure.		Per- centage of Oxygen.
	Baro- meter.	N.	O.	N.	O.	
0	772	19.85	10.15	19.53	10.01	38.88
+ 6.00	771	16.58	8.30	16.34	8.28	33.60
+ 6.32	741	16.20	8.18	16.60	8.30	33.55
+ 9.18	729	14.96	7.60	15.58	7.90	33.60
+ 13.70	771	14.37	7.24	14.16	7.14	33.51
+ 14.10	770	14.35	7.15	14.16	7.05	33.24

As the relative quantity of oxygen, nitrogen, and carbonic acid contained in a natural water gives important indications concerning its origin and condition as well as to its suitability for drinking purposes, it is desirable that greater

Two boiling flasks of about 100 cc. capacity containing 20 per cent. hydrochloric acid are employed. In one of them the carbonic acid is washed, after which it passes into the second flask. The second flask is provided with a syphon tube for withdrawing the solution of hydrochloric acid after it had been freed from oxygen. The results of the experiments are given, showing that the reagents thus prepared were free from oxygen. Another point is that the amount of oxygen which water is capable of absorbing from the air is influenced by the height of the column of water. Consequently it is best to calculate the solubility of gases in terms of a column whose height is = 0. It suffices to add half the pressure of the water column to the barometer reading and take that as the atmospheric pressure. The estimations were made as follows: A 4-litre flask (Fig. 2)

Fig. 2.

was half filled with carefully di-tilled water, and the neck closed with an india-rubber stopper through which passed two short straight tubes and one long bent one. Thoroughly purified air was led through the long tube and the contents of the flask shaken from time to time. The flask was kept at constant temperatures. When the water was thoroughly saturated with air the height of the barometer was noted, and by means of the arrangement shown in Fig. 3, some

Fig. 3.

of the water was carefully transferred to a carefully calibrated flask, one of the short tubes being meantime connected with the gas-holder supplying the pure air. The calibrated flask was taken out of the water-bath and the temperature of its contents carefully determined, the necessary reagents were then added, and the whole thoroughly mixed. The titration took place after 24 hours.

During this time the flask was closed against air entering by placing it stopper downwards in a beaker full of water. Detailed results of the determinations are given, and from

these have been calculated the solubility and absorption coefficient of oxygen. "That quantity of a gas reduced to 0° and 760 mm. which is dissolved by unit volume of a liquid at 760 mm. is the *solubility* (β') of the gas. On the other hand, the quantity which is taken up by a liquid when the pressure of the gas itself, without the tension of the liquid, amounts to 760 mm. is called the *absorption coefficient* (β) of the gas. In both definitions a column of liquid height = 0 is understood."

In the following table the results of the author's determination of the *absorption coefficient* (β') and the solubility of oxygen in water under normal pressure are compared with Bunsen's figures, and the last column (β' 209°6) gives the quantity of oxygen in cc. in 1,000 cc. of water saturated with air.

t degree C.	Bunsen's Absorption Coefficient.	β .	β' .	β' 209°6

—C. N. H.

Proceedings of the Austrian Society of Chemical Industry.
Meeting of June 1, 1889. Chem. Zeit. 13, 781.

J. Stoklasa drew attention to the solubility in water of crystallised calcium tetrahydrogen phosphate. According to the volume of water employed, the salt is more or less

decomposed into monohydrogen calcium phosphate and phosphoric acid, as shown below :—

Ratio of Salt to Water used for Solution.	Percentage of Salt Decomposed.
1 : 1	25
1 : 25	12.5
1 : 50	6
1 : 56	3
1 : 200	0.1

One part of calcium tetrahydrogen phosphate, therefore, requires 200 parts of water for complete solution. The liberated phosphoric acid was estimated by titration with decinormal soda and methyl orange, the total amount of phosphoric acid being determined with molybdic acid. The quantity of undecomposed phosphate in the filtrate from the monohydrogen calcium phosphate was calculated from the amount of calcium found.

The same chemist further mentioned a method of determining phosphoric acid in superphosphates, &c. 10 grms. of the superphosphate are brought into a litre flask and the flask filled to the mark. The solution is filtered, and 50 cc. of the filtrate are treated with ammonium citrate and magnesia mixture and shaken up for 5–6 minutes; then a volume of ammonia equal to one-fourth the volume of the mixture is added. The precipitated magnesium ammonium phosphate is collected, ignited, and weighed as pyrophosphate. The ammonium citrate solution is made by dissolving 250 grms. of citric acid in 500 cc. of water; 20 cc. of this solution, after neutralisation with ammonia, are used for the test. The following results show the accuracy of the method :—

Material Analysed.	Percentage of Phosphoric Acid.		
	Found by Ammonium Citrate Method.	Found by Molybdic Acid Method.	Calculated.

On Schützenberger's Process for the Estimation of Dissolved Oxygen in Water. Sir H. E. Roscoe and J. Lunt. J. Chem. Soc.

THE authors have lately made the above method the subject of careful investigation, and have succeeded for the first time in placing this important estimation on a satisfactory footing.

As the measurement of the amount of dissolved oxygen in waters, whether pure or impure, has an important bearing on many technical processes, it may not be unfitting to give a short account of this investigation in the Journal of the Society of Chemical Industry.

The method depends on the reducing action of sodium hyposulphite, Na₂S₂O₅,* on a blue solution of indigo-carmin. A dilute solution of hyposulphite added to the blue liquid turns it yellow; in this condition the liquid is a most delicate test for the presence of free oxygen, either gaseous or dissolved.

The process hitherto used may be given shortly as follows :—A large Woulff's bottle is filled with hydrogen, and about 30 cc. of water introduced into the vessel. To this liquid is added indigo-carmin sufficient to colour it

blue. Hyposulphite solution is now added from a burette until the blue is turned to yellow. The water to be examined is now added to the reduced solution, with an immediate restoration of the blue colour, due to oxidation by the dissolved oxygen contained in the added water. The amount of oxygen is estimated by noting the volume of hyposulphite required to restore the yellow colour, or in other words, that required to counteract the oxidation produced by the amount of oxygen added. Two curious observations had previously been made by Schützenberger and confirmed by other observers.† One was that after the estimation was effected as above described, the reduced yellow liquid quickly regained its former blue colour, and this, if again decolourised, repeatedly returned to blue until about double the previous amount of hyposulphite had been used.

The other observation was, that if a much larger quantity of indigo-carmin be employed, the amount of dissolved oxygen found is about double that obtained when only a small amount of indigo is used. Schützenberger's explanation being that the reaction between hyposulphite and dissolved oxygen is a different one to that taking place between hyposulphite and indigo-carmin; that in the former case half the oxygen became latent as hydroxyl, with subsequent slow liberation of oxygen, whilst in the latter reaction no hydroxyl was formed. Hence, in the first case, only half the total oxygen is obtained, whilst in the second the whole is found.

The authors explain these observations as follows :—

Low Result when the Water has been exposed to Hydrogen.—The cause of these anomalous results was indicated by an experiment in which the water to be analysed, contained in a Winchester quart bottle, was allowed to stand in an atmosphere of hydrogen overnight, estimations being made before and after such exposure. The results obtained show that diffusion is the disturbing influence, for when aerated water is introduced into an atmosphere of pure hydrogen it immediately begins to lose oxygen by diffusion into the hydrogen until an equilibrium is established. This is a fact hitherto overlooked by the experimenters with this process.

Explanation of the previous Experiments.—This explains the previous observations, viz., that the highest results are obtained when the hyposulphite is added quickly and immediately after the introduction of the water into an atmosphere of hydrogen, because the oxygen is estimated and combined before it has had time to diffuse to any great extent, the slight difference in the time of exposure between a quick and a slow titration being quite sufficient to give a marked loss of oxygen by diffusion during the slower addition of hyposulphite. The variation in the results of the apparently identical experiments first given, being explained by the slightly longer or shorter time taken over each titration, and the consequent greater or less facility for diffusion.

Results less in proportion to the amount of exposure to Hydrogen.—This conclusion, that diffusion is the disturbing influence, is borne out by further experiments easily suggested by the preceding.

Conditions influencing the Amount of Diffusion.—The rapidity and amount of the diffusion of dissolved oxygen depend on (1) the surface area of water exposed to hydrogen, influenced by the size and shape of the vessel and the degree of agitation during titration. (2) The volume of the atmosphere of hydrogen. (3) The time of exposure, up to the point of equilibrium (under the law of partial pressures). (4) The volume of water.

The authors show that the large size of the vessel hitherto recommended for the estimation is greatly conducive to the rapid loss of oxygen by diffusion, and by using the same solutions in a smaller titration vessel a greatly increased amount of oxygen was obtained.

Reason for the Return of the Blue Colour.—In carrying out the oxygen estimation in the usual manner, the blue colour after having once been destroyed by the hyposulphite almost immediately returns, and if this subsequent colouration be destroyed the colour will again return, and so on

* Prepared by the action of zinc dust on a strong solution of sodium bisulphite saturated with sulphur dioxide, with subsequent neutralisation by lime.

† Dupré, The Analyst, 10, 156; and Ramsay and Williams Chem. Soc. J. (Trans.) 49, 751.

for a long time. The blue colour returns even when the hydrogen used is perfectly freed from all traces of oxygen by passing through the two long tubes filled with beads moistened with the alkaline solution of potassium pyrogallate used in all our experiments.

No Return of the Blue Colour when Free Oxygen is Absent.—If the liquid containing indigo-carminc and also the atmosphere above it are perfectly free from uncombined oxygen, and hyposulphite be added until the blue is turned yellow, no return of the blue colour takes place.

Proof of the Diffusion of Dissolved Oxygen into Hydrogen.—A positive proof that when pure hydrogen comes in contact with aerated water it is contaminated with oxygen, has been obtained as follows:—

A large flask was filled with a fairly strong indigo-carminc solution which was decolourised carefully with hyposulphite. Matters were so arranged that pure hydrogen, freed from all traces of oxygen as before stated, could be passed through aerated water, and thence into the large flask, driving out the sensitive yellow liquid through a tube passing to the bottom of the flask. In this way the hydrogen, contaminated with oxygen from the aerated water, is imprisoned above a solution which will indicate the presence of oxygen by the formation of a blue colour. This blue colour was observed at the surface of the liquid, and after a few minutes it became very intense and unmistakable.

Influence of the Amount of Indigo-Carmine used.—These experiments explain a singular observation made by Schützenberger, namely, that by using a small amount of indigo-carminc only half the dissolved oxygen is estimated,

when the first decolourisation of the solution is effected; whilst when a much larger quantity of indigo-carminc is employed the whole of the dissolved oxygen is found. The explanation given by him being that the reaction between reduced indigo and dissolved oxygen is a different one from that taking place between hyposulphite and dissolved oxygen, inasmuch as in the latter reaction half the oxygen becomes latent as hydroxyl with subsequent slow liberation of oxygen, whilst in the former no hydroxyl is formed.

His observation, however, will bear another interpretation, namely, if more reduced indigo be present than is sufficient to combine with all the dissolved oxygen contained in the added water, this oxygen is immediately combined by the reduced indigo and its diffusion prevented. Hence all the oxygen is obtained. The use of so large a quantity of indigo, however, so disturbs the end-reaction, from the presence of so much of the yellow compound, that "it is difficult to fix the point at which the last trace of blue has been discharged with any degree of accuracy." (Dnpré.)

A new method must satisfy the following conditions:—

(1.) The aerated water must not at any time expose its uncombined oxygen to an atmosphere of hydrogen.

(2.) Precautions must be taken to ensure the use of an atmosphere perfectly free from oxygen, and the apparatus used must not permit any ingress of air.

(3.) When the vessel in which the analysis is made is first filled with water to expel air or to obtain the sensitive yellow liquid, the first portion of gas, having been in contact with aerated water, is contaminated with oxygen and must be entirely driven out.

Apparatus adopted.—Fig. 1 shows the apparatus adopted by us for carrying out the estimation.

Fig. 1.

It consists essentially (1) of an apparatus for the continuous generation and purification of hydrogen, by the action of dilute sulphuric acid on zinc; (2) a 200-cc. wide-mouthed bottle fitted with three burettes with glass taps, inlet and outlet tubes for a current of hydrogen, and an outlet tube for the titrated liquid; (3) Winchester stock-bottles of hyposulphite, indigo (not shown), and water, communicating with their respective burettes by glass siphons.

The hydrogen generated in A passes through two wash-bottles containing caustic potash, thence through two Emmerring's tubes filled with glass beads moistened with an alkaline solution of potassium pyrogallate, an arrangement being made whereby the beads may be re-moistened with fresh pyrogallate from the bottles beneath, the liquid being forced up by hydrogen pressure.

Pure hydrogen is supplied continuously (1) to the stock-bottle of hyposulphite, (2) to the hyposulphite burette, and (3) to the titration bottle.

The New Method.—A sample of water is examined as follows:—

(1.) 20 cc. of the water is introduced into the small bottle and about 3 cc. of indigo solution added.

(2.) A moderate current of hydrogen is passed through the blue liquid by a very fine jet for three minutes to free both water and supernatant gas from free oxygen.

(3.) Hyposulphite is now carefully added, during the flow of hydrogen, until the change from blue to yellow occurs, taking care not to overstep this point.

(4.) A further measured quantity of hyposulphite is now added (say 10 cc.) sufficient to combine with all the dissolved oxygen in the volume of water, 50–100 cc., proposed to be used in the estimation.

(5.) The important point now is, that the water is run in from a burette by a capillary tube passing *beneath the surface of the liquid* to the bottom of the vessel. Thus we introduce the water into a liquid which will at once combine the free oxygen, and thus prevent its diffusion on coming in contact with the hydrogen, the reduced indigo acting as an indicator for the complete oxidation of the hyposulphite. The liquid is kept in constant motion during the addition of the water, which is shut off the moment a permanent blue colour appears.

(6.) The blue is decolourised by a further slight addition of hyposulphite. The volume of water used, and the total hyposulphite, minus the first addition, are noted, and the estimation repeated for confirmation.

When the water contains very little oxygen the second addition of hyposulphite may be omitted, the reduced indigo-carmin being sufficient to take up all the dissolved oxygen. In this case, care must be taken that the oxygen added should require not more than half the hyposulphite first added to decolourise the indigo-carmin.

Standardisation of the Hyposulphite.—In order to complete the estimation it is necessary to know the strength of the hyposulphite solution employed. This has entailed a very considerable amount of labour, inasmuch as of the two methods hitherto adopted for this purpose, the first was found to be fundamentally wrong, and the second to depend on erroneous data.

The authors examine the copper method of standardisation, depending on the decolourising effect of hyposulphite on a standard solution of ammonio-cupric sulphate.

They adopt the method of standardisation depending on a titrating of fully aerated distilled water, aerated at a known temperature and pressure, but find, on investigation, that the oxygen value of such water is inaccurately given by Bunsen's coefficients of absorption, previously used for the standardisation, and they substitute the following values which they have determined by using apparatus specially constructed for the purpose of extracting the dissolved gases by boiling the water *in vacuo*, and subsequently measuring the volume of oxygen.*

Method of Aeration.—Before giving the results of the estimations made with distilled water saturated with air, it is necessary to describe the method of aeration.

Freshly distilled water adjusted to the required temperature was aerated by vigorous agitation in two Winchester

quart bottles half full of water, the air being renewed five or six times by emptying the contents of one bottle into the other and again dividing into two portions, which were repeatedly agitated with fresh air.

When aerated, one bottle was filled and allowed to stand, stoppered, for half an hour to an hour, to get rid of minute air-bubbles. Then the gases were extracted and analysed, the barometer having been read to obtain the pressure at which the water was aerated.

The numbers obtained indicate close agreement between the several experiments at each temperature, and also throughout in the ratio between the oxygen and total oxygen plus nitrogen, a ratio always between 33 and 34 per cent.

They show a wide discrepancy from Bunsen's numbers, but agree well with Dittmar's determinations.†

The following table has been constructed, giving the oxygen values for fully aerated distilled water for each half degree between 5 °C. and 30 °C., and for an *observed*‡ pressure of 760 mm.:—

OXYGEN DISSOLVED BY DISTILLED WATER. 5°–30° C.

Indigo Standardisation.—When once the hyposulphite has been carefully standardised by distilled water, this rather troublesome aeration may be avoided by finding the oxygen-value of the indigo-carmin solution. This solution, remaining constant may be used for the subsequent standardisation of the hyposulphite.

* "Challenger" Reports, Vol. I., Pt. I, p. 160.

† In this table the results are calculated for aeration at an *observed* barometric pressure of 760 mm. When the observed pressure is *below* 760 mm., the value must be *subtracted* for every 10 mm. diff. The same value must be *added* when the pressure is *above* 760 mm.

It is only necessary to take a suitable quantity of indigo solution, diluted with water if necessary, free it from all dissolved oxygen by a current of pure hydrogen continued for five minutes, they carefully decolourise with hyposulphite, the value of which has been carefully found by using aerated distilled water. The hyposulphite solution slowly loses strength even when kept in hydrogen, and should be standardised daily when required to be used.

Comparison of the New Method with the Volume of Gas found.—We next proceed to apply the volumetric process as thus modified to the examination of samples of water from different sources, and to compare the results with the absolute volume of gas obtained by boiling out the same water *in vacuo*.

A further comparison was made with very impure Thames water collected at Crossness, opposite the southern outfall for London sewage, 12 miles below London Bridge.

These in like manner indicate that the method gives good results, even with an impure water of this character.

The process thus applied to waters of such varied character, and containing such widely different amounts of oxygen, with a mean difference of only 0.5 cc. from the value obtained by extracting and measuring the gases, shows that, although perfect accuracy cannot be guaranteed for the process thus improved, yet the results obtained are not far removed from the truth, and certainly give very valuable indications as to the oxymetric condition of samples of water submitted to its operation.

Influence of Acidity and Alkalinity.—Although the method is applicable to pure and impure waters, and even to brackish waters, this is not the case if the water contains even small quantities either of free acid or alkali. Thus, if $\frac{1}{1000}$ th part of sulphuric acid be added to pure water, not only is the oxygen value obtained a different one, but the whole reaction is disturbed. The volume of hyposulphite required for the first decolourisation is greater; this only produces a light straw-yellow, instead of the fine deep yellow of a normal titration. The delicacy of the reaction is altogether destroyed, a much larger volume of water than usual only slowly producing a light blue colour, instead of the distinct colouration produced by even half a cubic centimetre of pure water in a normal titration. Oxalic acid has a similar action. The same proportion of ammonia has an entirely opposite effect. The oxygen value is raised instead of lowered, and the delicacy of the reaction is not impaired, although the colour reaction is very much modified.

Sodium bicarbonate has no effect.

Of course, when other substances than oxygen, which decompose hyposulphite, are present in the water, the accuracy of the method is proportionately disturbed.

Delicacy of the Reaction.—With pure water, the change of colour is a very highly sensitive reaction and the most delicate test for the presence of free oxygen we possess, one part of oxygen in two million parts of water being sufficient to bring about a distinct change of colour.

Diffusion of Oxygen through India-rubber.—The delicacy of this reaction may be employed to show the rapid diffusion of atmospheric air through india-rubber tubing. The experiment is made as follows:—

100 cc. of water and 3 cc. of indigo-carmin are freed from oxygen and decolourised in the usual way. The liquid is then forced out by hydrogen pressure on opening A.

When the liquid has flowed through B, C, D, E, for a few seconds, the pinch-cock A is closed.

The liquid is seen to be yellow at F, B, and D, and is allowed to remain in the india-rubber tube C for five minutes. If now A be carefully opened, so as to allow the former contents of C to be seen in the glass tube D, it will at once be observed that whilst the liquid in F, B, and D had remained unchanged, that in C had turned quite blue, from the absorption of atmospheric oxygen diffused through the india-rubber. Even one minute's exposure is sufficient to give an indication.

This experiment has a practical bearing on the construction of the apparatus as figured in Dupré's paper and in Sutton's work on volumetric analysis, 5th edition, in which the hyposulphite solution is made to pass through several

feet of india-rubber tubing before reaching the titration vessel, its strength, of course, diminishing with the time of remaining in contact with the india-rubber.

Fig. 2.

In the form adopted by the authors, the hyposulphite is conveyed from the stock-bottle to the titration vessel by a glass syphon, and only sufficient india-rubber used to accommodate a pinch-cock and to make one other connexion necessary for the free motion of the titration vessel.

Suggested Applications of the Method.—This process is perhaps most applicable to water analysis. It is well known that organic and bacterial contamination most frequently exist side by side, the one calling forth the other. The activity of these micro-organisms shows itself in the diminution of the dissolved oxygen, which is used up by the bacterial forms during their active life in changing the organic impurities present in the water. Then, again, the process might be used in the brewery, more especially at the fermentation stage of the wort. The deleterious effect of a sluggish fermentation is often felt by the brewer, and this may be due in part to the low state of aeration of the wort.—J. L.

Estimation of Ferrocyanogen in Spent Material from Gas Purification. O. Kumblauch. Jour. f. Gasbeleuchtung, 1889, 450—459 and 493—500.

The author points out that the difficulties surrounding the estimation of ferrocyanides in spent gas purification material arise from the impurities present, and he asserts that neither titration with copper sulphate nor with permanganate give reliable results, inasmuch as, in the latter case, the material in question always contains substances other than ferrocyanides which are readily oxidised by permanganate, even after the removal of thiocyanates. Whilst in the former case the impurities interfere either by directly reacting with the copper sulphate or by impairing the delicacy of the end reaction. Moreover, neither the amount of iron nor cyanogen present can be regarded as an accurate measure of ferrocyanides; for according to our present knowledge of their composition it cannot be stated with certainty that these constituents are really present in the form we assume them to be—in fact, the author has come across compounds which resemble, but which are not identical with ferrocyanides. Attention is drawn to the difficulty of removing all the iron not in the form of ferrocyanide in the presence of the different kinds of organic matter present; the author has also observed the decomposition of ferrocyanides with the deposition of iron hydroxide. In both these cases the iron numbers would give incorrect results. In fact, the author has come to the conclusion that

there is no method by which the commercial value of the spent material can be accurately gauged, and therefore he suggests that a method ought to be adopted which will give some insight into the technical value of the material, and involve processes similar to those used in its technical application. And with this object in view, he has devised a method on the following scheme:—Conversion of the insoluble ferrocyanogen into soluble ferrocyanides, purification of the extract, and then estimating the ferrocyanide direct by titration with copper sulphate. Having ascertained, in a series of special experiments, the temperature at which the drying might be conducted without decomposing the material; the conditions under which the conversion of insoluble into soluble ferrocyanides might be effected with the smallest production of substances which would interfere with the titration, such as the quantity and strength of the potash duration of, and temperature during contact; best means of removing interfering substances; modes and accuracy of testing—after completing these investigations, the author incorporated the results in, and adopted the following method:—The whole sample of 200–250 grms. is dried at 50–60° C. until of constant weight, taking from 5 to 6 hours. The dried sample is pulverised, and passed through a sieve with 360 meshes to the square centimetre; if any sawdust is present it remains on the sieve, and is weighed separately. 10 grms. of the sifted stuff is treated in the cold with 50 cc. of a 10 per cent. solution of potassium hydroxide in a flask marked at 250 cc., and at 255 cc., either for 15 hours with frequent agitation, or for 16 hours agitating only during the first and last two hours, the flask is then filled to the 255 cc. mark, and the contents filtered. 100 cc. of the filtrate is run into a hot solution of ferric chloride, containing 60 grms. of ferric chloride, and 200 cc. of hydrochloric acid (sp. gr. 1.19) per litre, and the whole filtered hot (at about 80° C.) through a folded filter covered over in a hot water funnel, the precipitate is washed with hot water, but not for too long a time. The filter is spread in a porcelain dish, and treated with 20 cc. of 10 per cent. potash, taking care that none of the Prussian blue escapes decomposition; the liquid is washed into a quarter litre flask, and tested for hydrogen sulphide with sodium nitroprusside. If there is not an immediate and distinct reaction, the liquid is filtered, 50 to 100 cc. acidified with 2.5 or 5 cc. of sulphuric acid (1:5), and titrated with copper sulphate. If hydrogen sulphide is present, the unfiltered liquid is treated with 1 to 2 grms. of lead carbonate, filtered quite clear, and then titrated. The copper sulphate solution contains 12 to 13 grms. per litre, and is standardised by titrating with a solution of pure potassium ferrocyanide containing 4 grms. per litre. To test the completion of the reaction either the spot or filter test is employed; in the former a drop of the liquid is placed on filter-paper, and a drop of ferric chloride is placed near it; then, as the drops spread and come in contact, the appearance of a blue colouration where the liquids meet indicates incomplete reaction; but where this formation of the blue ceases to be observed the action is completed according to this test. In the filter test a portion of the liquid is carefully filtered through a minute filter, and the clear liquid tested with ferric chloride; this is the more delicate test, and therefore always registers slightly higher results than the spot test. Care must be taken to always use the same proportion of acid in the titration, and to allow, in all cases, the same time for the copper sulphate to react, and also for the appearance of the blue colouration in testing: 2 minutes for the spot test, and $\frac{1}{4}$ to $\frac{1}{2}$ minute for the filter test. Calculations may be based on either the spot or filter litre except when lead has been used, then the latter only must be used for the calculations, which are simple enough. Multiplying by 0.541 converts percentage of potassium ferrocyanide into hydroferrocyanic acid; by 0.678 into Prussian blue; by 0.369 into cyanogen; by 0.383 into hydrocyanic acid.

As a rule the spot and filter titrations only differ from 0.2 to 0.6 cc. when from 8 to 12 cc. of the copper solution of the above strength is used, and the addition of the last $\frac{1}{10}$ cc. of copper solution is sufficient to dispel the blue colouration which gives way to a brownish hue or to a colourless state. Another point is that most filter-papers contain sufficient

iron to give the blue colouration without any further addition of iron, and with pure ferrocyanides and most samples of spent material from gas purification, the titrations obtained by the spot test with and without the addition of iron are alike. But the author observed that sometimes instead of the blue colour giving way readily in the usual manner, the solution in the filter test remained persistently green or greenish-yellow, the consequence being that the filter test registered much higher than the spot test; moreover in such cases the spot test with iron registered higher than the spot test without iron. A number of experiments were instituted to inquire into this matter, and it appears to be due to those substances already referred to, which apparently contain iron and cyanogen in varying quantities; they also contain sulphur. They appear to undergo decomposition and gradually yield ferrocyanides. They are dissolved by potash, and are apparently precipitated by ferric chloride, but are not, it seems, of the same value as ferrocyanides, but as they undergo conversion they ought to be estimated. In fact, on keeping for some time they disappear, and material containing them will after some months cease to show indications of them, and the spot and filter titrations will be normal; so also material which has been stored or regenerated does not contain them. The author suggests, as the outcome of his experiments, the following method of correcting for these impediments:—Add to 200 or 300 cc. of the solution slightly more copper sulphate solution than is required by the spot titration, too little copper sulphate causes decomposition even with pure ferrocyanide; filter, pour the filtrate into hot ferric chloride, decompose and titrate the Prussian blue formed, and, if it is thought desirable, the filtrate from this precipitate is treated in the same manner. The numbers obtained in this way are added as corrections to the numbers obtained in the usual manner, and it is then found that the spot and filter titrations approximate more and more, the latter becoming less the former increasing. It therefore seems that in these cases the spot test shows too little and the filter test too much, and therefore an alternative for the fractional titration would be an agreement between the parties concerned to adopt some mean result for the basis of valuation; for instance, mean of the spot test without iron and the filter test. Tables of analytical results of the examination of some purification materials are given. It is pointed out that in valuing material the ferrocyanogen as well as the hydrogen sulphide absorbing power must be considered.

The Separation of Copper from Antimony. Finkener. Mith. Königl. techn. Versuchs. 1889, 76–86.

Fine separation is effected in two stages: first by the precipitation of the bulk of the copper, as cuprous iodide in an acid solution, and then by the removal of the remainder as sulphide in an ammoniacal solution. The author has established the following facts, serving as a basis for his method:—

- (1) Cuprous iodide carries down antimony even in the presence of tartaric acid from a nitric acid solution of the two metals, but does not do so if the antimony be first converted into a double salt of antimony pentafluoride and an alkaline fluoride by the addition of the latter.
- (2) Free iodine in the presence of an alkaline fluoride converts antimony trifluoride into the pentafluoride, though somewhat slowly; the process is hastened by heat and the addition of sulphuric acid.
- (3) Sulphurous acid reduces antimony pentafluoride slowly in the presence of potassium iodide; the addition of hydrochloric acid hastens the reaction, but the presence of potassium fluoride almost completely inhibits it.

From this the following method is derived:—If the solution to be treated contain the antimony as a pentad compound all that is necessary is to add an alkaline fluoride, then potassium iodide and sulphurous acid, heat gently, filter off the bulk of the copper as cuprous iodide, and wash with boiling water made acid with sulphuric acid. In the event of the antimony being in the triad state the

solution may be first treated with chlorine or bromine water, or oxidation may even be effected by the iodine liberated by the action of the cupric salt also present on the potassium iodide, provided time be allowed for it before the addition of sulphurous acid.

The filtrate containing all the antimony and a little copper is oxidised by bromine water, and the metals precipitated together by sulphuretted hydrogen, the mixed sulphides dissolved in hydrochloric acid with the addition of potassium chlorate, ammonium tartrate added, and ammonia in excess: the resulting solution is heated on a water-bath and sulphuretted hydrogen water added little by little until no further precipitation occurs. By thus minimising the quantity of ammonium sulphide present, re-solution of cupric sulphide is avoided.

The filtrate containing only the antimony is acidulated with sulphuric acid and sulphuretted hydrogen passed through; the antimony is determined in the sulphide thus precipitated by heating it, together with its filter, with hydrochloric acid, and determining the sulphuretted hydrogen evolved by standard iodine solution. The author has established that antimony sulphide precipitated in the presence of sufficient ammonium tartrate to convert all chlorine present into ammonium chloride is of normal composition, and yields the theoretical quantity of sulphuretted hydrogen when heated with hydrochloric acid. (Rose, *Analyt. Chem.* 6th edit., II., 478.)

The analytical results quoted show the method to be reliable, if potassium or sodium fluoride in the proportion of about 1 gm. to 0.275 gm. of antimony be used, and the solution in which the first stage of the separation is effected be about 200 cc.

The process is also stated to be equally applicable to the separation of copper and arsenic.—E. E. B.

Analysis of Crude Tartrates. N. v. Lorenz. *Chem. Zeit.* **13**, 693—694.

THE author defends the statements made by him in a former criticism upon Goldenberg's original process for analysing tartrates (this *Journal*, 1888, 136 and 239).

—E. E. B.

On the Sulphate and Carbonate of Lithium. F. Kobbé. *Pharm. Zeit.* **34**, 312.

IN most text-books it is stated that lithium sulphate is soluble in alcohol. This, according to the author, is not correct, as lithium sulphate is insoluble in strong alcohol, though it is taken up, according to the quantity of water present, by dilute alcohol. On this account the following method adopted by the German Pharmacopœia for testing the freedom of lithium carbonate from potassium, sodium and magnesium salts is not satisfactory:—"0.1 gm. of lithium carbonate dissolved in a few drops of dilute sulphuric acid must yield a clear solution on addition of 4 grms. of alcohol." Under these conditions even the purest carbonate gives a marked precipitate, on account of the insolubility of the lithium sulphate. The author suggests the following:—

A solution of 0.5 gm. of lithium carbonate in 10 grms. of dilute sulphuric acid must remain clear on addition of 20 cc. of alcohol; 3 per cent. of potassium carbonate or 0.5 per cent. of calcium carbonate produces a turbidity.

—O. H.

The Presence of Pyridine in Amyl Alcohol; a New Compound of Picric Acid. H. von Asbóth. *Chem. Zeit.* **13**, 871—872.

A NUMBER of specimens of amyl alcohol were found to yield, when used as a solvent for picric acid, crystals of what proved to be pyridine picrate, thus pointing to the presence of pyridine in the samples tested, none of which had been denaturated. Hungarian amyl alcohol was found to be free from pyridine, and this is considered by the

author to be due to the fact that in Hungary the spirit is distilled by steam (Bohm-Fredersdorf or Ilges' method is employed), whilst in many parts of Germany from which the samples containing pyridine were got, Dorn's or Pistorius' distillation apparatus is in use. In these the flame comes into direct contact with the boiler containing the alcohol, and any insoluble matter contained originally in the mass would probably be carbonised, yielding pyridine as a decomposition product. Recently the steam distillation apparatus has been more extensively in use in Germany than heretofore, and samples of amyl alcohol obtained in 1888 were found to be free from pyridine. The pyridine picrate forms needle-shaped crystals which are difficultly soluble in alcohol and in cold water. They melt at 141.5°, and are decomposed by strong acids or bases with separation of pyridine. Heated gently they are partially decomposed; strongly heated they explode. Their formula is $C_5H_5N.C_6H_2(NO_2)_3.OH$. To employ this picrate as a test for the presence of pyridine in amyl alcohol, picric acid is dissolved in the sample, the solution filtered and the crystals which separate on cooling recrystallised from hot water.—C. A. K.

Distinction of Resorcinol from Carboic Acid and from Salicylic Acid. H. Boddé. *Nederl. Tijdschr. v. Pharm. Chem. en. Toxikol.* 1889, **1**, 163.

A SOLUTION of resorcinol, either in water or in alcohol, gives a violet colouration on addition of a drop of sodium hypochlorite which soon turns yellow, and which on warming or on further addition of hypochlorite becomes dark yellow, red, or dark brown. One part of resorcinol in 10,000 parts of water can be detected by the violet colouration. Carboic acid, salicylic acid, benzoic acid, and allied bodies do not give the violet colouration, the solution either remaining colourless or showing a slight fluorescence; on warming it turns slightly yellow. A solution of resorcinol treated with a few drops of ammonia and then with a few drops of sodium hypochlorite gives a red-violet colouration which turns yellow on standing and dark green on boiling. Salicylic acid, benzoic acid, and antifebrin give no colouration with this reagent; phenol gives a blue-green colouration.—C. A. K.

The Flashing Point of Mineral Lubricating Oil. Holde. *Mitth. Königl. techn. Versuchs.* 1889, 64—75.

THE objections that are now conceded with respect to the methods of determining the flashing point of kerosene, formerly in use, are valid in the case of mineral lubricating oils. An apparatus on the lines of the Abel instrument is what is needed. A modification of the Pensky apparatus (Schädlér's *Fette u. Oele d. Fossilien*, p. 443) was devised and is shown in the accompanying figure. The chief point in which it differs from the Abel oil-tester is the presence of an agitator with two sets of blades, so that both the oil and the atmosphere in the cup immediately above it are kept homogeneous. By this means local inequalities in the heating are obviated, a result which is also favoured by the even distribution of the hot gases from the lamp shown beneath the vessel itself. On this account there is little fear of arriving at an erroneous result by moderately rapid heating, a risk attending the use of the older forms. A rise of 12° C. per minute towards the close of the experiment may safely be adopted.

Some oils contain much water and give very irregular values for their flashing points. The presence of moisture may be recognised by heating the oil in a test tube in a clear oil-bath kept at about 140° C. As its temperature approaches 120° C. it begins to froth and may even "bump," while the film of it on the walls of the test tube is seen to be an emulsion of water and oil, and does not become clear even at 150° C. It is easy to distinguish these indications of the presence of water from those of entangled or dissolved air which is sometimes present. It is of course necessary in making this experiment (as in sampling the oil) to avoid even a trace of moisture in the vessels used.

Section through the Middle.

The results of numerous experiments demonstrating the closeness of the agreement of the figures obtained by the use of this apparatus, and the unreliability of more primitive methods, are recorded in voluminous tables.—B. B.

Detection of Mineral Oil in Fatty Oils. Holde. Mith. Königl. techn. Versuchs. 1889, 75.

BENEDIKT'S process ("Analysen der Fette und Wachstern," p. 102), which consists in saponifying the oil with alcoholic potash, and adding ammonia to the solution, thus producing a turbidity if mineral oil be present, needs attention to be paid to his prescription, as a too weak alcohol fails to yield a clear solution, even with pure fatty oils; a large excess of ammonia, too, causes in any case a precipitate, the potash soap being thrown down.

The author describes and recommends the following method:—A piece of caustic potash the size of a pea is heated in a test tube with about 5 cc. of absolute alcohol until dissolved; three or four drops of the suspected oil are then added, the heating continued for one minute and 3 or 4 cc. of distilled water added. If the solution remain clear a fatty oil only is present. Any little flocks of soap visible before the addition of water dissolve afterwards; even 1 per cent. of mineral oil causes the formation of a distinct turbidity.—B. B.

Estimation of Lime in Soils. F. Reverdin and C. de la Harpe. Chem. Zeit. 13, 726.

The lime present in soils serves different purposes. Not only does it act as a binding material for the soil and a promoter of the oxidation of the nitrogenous organic matters, but it also serves as an important plant food. And in these respects all lime salts do not act alike, for whilst, for instance, finely-divided calcium carbonate assists the formation of nitrates, calcium sulphate acts indifferently. It is therefore of importance to estimate the directly active lime in making an analysis of soil. P. de Mondesir does this by measuring the volume of carbonic acid gas which is liberated by treating the soil with tartaric acid. But this treatment causes the lumps of calcium carbonate to be dissolved, and as only the surface of the same is active, the method is unsatisfactory. The authors propose the following method: The sample of soil is digested on the water-bath for several hours with an excess of a mixture of equal molecules of sodium oxalate and carbonate. The sodium oxalate solution must have been standardised and the mixture be so concentrated that about 200 cc. will suffice for 20 grms. of the soil. The solution is filtered, the residue washed, the washings being added to the filtrate, and then the filtrate is acidified with hydrochloric acid. In most cases a precipitate of organic acids is produced, which must be filtered off. Sodium acetate is then added to the filtrate, and, after boiling, calcium chloride solution is added to precipitate the excess of oxalic acid, which is estimated with permanganate in the usual way. From the amount of oxalic acid which is found to be absorbed by the soil, may be calculated the quantity of active lime present. The carbonate of soda causes the magnesia to remain in the form of magnesium carbonate, whilst the sodium oxalate changes the finely divided calcium carbonate and other lime salts into calcium oxalate, but attacks only the surface of the lumps of calcium carbonate.—E. B.

Quantitative Determination of Methoxyl ($O.C_2H_5$). R. Benedikt and H. Grüssner. Chem. Zeit. 13, 872—873.

The method is a modification of that proposed by Zeisel (see this Journal, 1886, 335).

The substance (0.2 to 0.3 gm.) is placed in the flask A, the capacity of which is 30—35 cc., and there treated with 10 cc. of hydriodic acid of sp. gr. 1.70. A current of carbon

dioxide is passed through the flask, the heating of the latter being effected by a glycerol bath. The methyl iodide formed passes through the three bulbs I., II., and III. I. is empty, II. contains water, and III. water containing red phosphorus in suspension. These bulbs are surrounded by water, the temperature of which can be kept at 70° C. by passing in hot water; this is necessary in the determination of ethoxyl ($\text{O.C}_2\text{H}_5$). After passing the bulbs, the methyl iodide, which is quite free from hydriodic acid and iodine, is absorbed in the flask B by 5 cc. of a 40 per cent. solution of silver nitrate and 50 cc. of 95 per cent. alcohol. D is a safety flask containing 1 cc. of silver solution and 10 cc. of alcohol, but it was never found to contain a weighable quantity of silver iodide. The alcoholic solution is diluted with water, acidified with nitric acid, and the silver iodide filtered off and weighed.—C. A. K.

Volumetric Determination of Carbon Dioxide. F. Fuchs, Chem. Zeit. **13**, 873.

The flask A is partially filled with dilute hydrochloric acid and this then saturated with carbon dioxide either by passing

the gas into the acid or by adding sodium carbonate. In this way the space above the acid becomes entirely filled with carbon dioxide at the end of the determination, thus avoiding any error due to the varying composition of the gaseous layer above the acid. The exit tube B is filled with dry air and inserted in the stopper C. The substance is placed in the small bottle D and held in a hole in the stopper, from which it is liberated by pressing down the glass rod above it. The liberated gas is measured as usual. Results varying from 0.07 to 0.37 per cent. from the theoretical value are given.—C. A. K.

Simultaneous Determination of Hydrogen and of Nitrogen. C. Gehrenbeck. Ber. **22**, 1694-1696.

The combustion is carried out in an ordinary combustion tube open at both ends, in which the substance, intimately mixed with cupric oxide or with lead chromate, is placed. The stopper at the one end of the tube is furnished with a tube provided with a two-way cock, one passage of which communicates with an ordinary drying apparatus for air and oxygen, the other with a carbon dioxide generator. The calcium chloride tube is connected to the other end of the combustion tube, and attached to it is the apparatus for collecting the nitrogen (Schiff's apparatus was used). A second small calcium chloride tube is interposed between the two to prevent any sucking back of the liquid from the nitrogen apparatus into the calcium chloride tube. To conduct the analysis the whole apparatus is first filled with carbon dioxide (dried by means of sulphuric acid) and the

nitrogen determination made in the usual way. The two-way cock is then turned and the combustion completed in oxygen, this last being finally displaced by air.

Several test analyses are given with satisfactory results.
—C. A. K.

A New Method for the Quantitative Determination of Nicotine. M. Popovici. Zeits. f. Physiol. Chem. **13**, 445.

FIFTY grms. of the tobacco powder are moistened with 10 cc. of alcoholic soda solution (6 grms. of caustic soda in 40 cc. of water, with 60 cc. of 95 per cent. alcohol) and then extracted in a Soxhlet apparatus for 3-4 hours with ether. The extract is shaken with a moderately concentrated solution of nitrophosphomolybdic acid. The precipitate, which readily settles, after drawing off the ethereal layer is made up with water to 50 cc. and the nicotine set free by the addition of 8 grms. of finely-powdered barium hydroxide. The alkaline product containing free nicotine is filtered, and the rotary power of the filtrate determined in the polariscope; from this the quantity of nicotine can be found in a table prepared by the author, who employed ethereal solutions containing known amounts of nicotine, which was precipitated and treated as above, the rotary power being determined through a layer of the solution 20 cm. thick. Higher results are obtained by this process than by Kissling's; this is attributed by the author to the fact that some of the nicotine is lost in the latter process in distilling off the ether.—O. H.

New Books.

OEL- UND BUCHDRUCKFARBEN. Praktisches Handbuch für Firniß- und Farbendfabrikanten, von LOUIS EDGAR ANDÉS, Lack- und Firniß-Fabrikant. Mit 56 Abbildungen. All rights reserved. Wien, Pest und Leipzig. A. Hartleben's Verlag, 1889. London: H. Grevel and Co., 33, King Street, Covent Garden.

SMALL 8vo volume, bound in paper cover, price 4s. It contains 261 pages of subject-matter and 56 wood engravings. The treatment of the entire subject may be best exemplified by a summary of the contents, as follows:—Linseed oil; Purification and Bleaching of Linseed oil; Machinery and Apparatus used in purifying and bleaching oils. Chemical purification of Linseed oil. Oxidising agents for the conversion of Linseed oil into varnish. Theory of Varnish making. Manufacture of Linseed oil varnishes. The Colouring materials for paint—Artists' Oil—and Bright Printing Colours. The Colouring materials for Printers' black inks. Substitutes for Lampblack. Apparatus for Grinding and Triturating Colours. Mechanical arrangements for mixing the Binding materials with the Colours. Machines for grinding Colours. The Manufacture of Colours for Oil paints. Artists' Oil Colours. The Manufacture of Book Printing Colours. Composition Varnishes. Mixing the lampblack with the Varnish. Recipes for Printers' blacks. Improvements in the preparation of Book-printing Colours by Dr. H. Brackenbusch, &c., &c. The work closes with a full alphabetical index.

CHEMISCHE HOMOLOGIE UND ISOMERIE in ihrem Einflusse auf Erfindungen aus dem Gebiete der organischen Chemie. Eine patentrechtliche Studie von Standpunkte des Chemikers. Von DR. OTTO N. WITT. 1889. Berlin: Verlag von Rudolf Mückenberger. London: H. Grevel and Co., 33, King Street, Covent Garden.

THE object of this work (price 5s.) is briefly to discuss the relative positions of the organic chemist, discoverer, inventor, and patentee. It is an octavo volume of pamphlet form, containing 96 pages of text, and dedicated to Dr. H. Caro, the

well-known chemist, and Director of the Badische Anilin und Sodafabrik. It is subdivided as follows:—**PART I.** The Patent Laws of different Countries, and their Influence as regards Chemical Discoveries. **PART II.** Chemical Discovery and its Relations to Chemical Construction. **PART III.** Chemical Homology and Isomerism. **PART IV.** Homology and Isomerism as regards their Influence on the Patent System. **PART V.** Examples:—No. 1. Example of a Process which is distinguished from an already known Method by the Employment and Production of Homologous Substances. Consequences of this Homology. No. 2. Rejection of a Patent on the Ground of the Isomerism of the Ingredients used with Substances already known. No. 3. Granting of a Patent in spite of the Isomerism of the Products employed and produced with those of a Process already patented. No. 4. Granting of a Patent on the ground of the different Colour of the Isomerides obtained by the Process for which Protection is sought from that of already patented Isomerides. No. 5. Decision of the Government Jurisdiction of the 20th March 1889. **PART VI.** Final Conclusions.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von DR. EMIL JACOBSEN. 1888. *Zweites Halbjahr.*—*Erste Hälfte.* Berlin: R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder, London: H. Grevel and Co., 33, King Street, Covent Garden.

OCTAVO volume in paper cover; the first issue for the second half-year of 1888. It contains 160 pages of subject-matter, plentifully illustrated with wood engravings, and in the former the following subjects are treated of:—

Building materials, Cements, Artificial stone, Colouring Matters, Dyeing and Printing. Fats, Oils, Illuminating and Heating materials. Fermented liquors. Tanning, Leather, and Glue making. Textiles. Glass and Earthenware. Wood and Horn. India-rubber. Cements, Gums, &c. Lakes, Varnishes, and Paints. Metals.

Trade Report.

(From Board of Trade and other Journals.)

RAILWAY AND CANAL TRAFFIC ACT, 1888.

On page 249 of the *Board of Trade Journal* for September will be found the text of a memorandum issued by the Board of Trade on this subject on the 8th August last.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Franc = 9 ¹⁶/₁₀₀d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities during the month of July last:—

Fluoride of silicon and sodium (fluosilicate).—Category 17. Duty, 1 franc per quintal.

Paper used as blue for linen.—Category 38. Duty, 16 frs. per quintal.

Saccharin.—Category 246. Duty, 10 frs. per quintal.

Malt extract, in bottles or jars, with or without label.—Category 248. Duty, 10 frs. per quintal.

ITALY.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Lire = 9 ¹⁶/₁₀₀d.

The following decisions affecting the classification of articles in the Italian Customs tariff have recently been given by the Italian Customs authorities:—

Carbonate of lime obtained by precipitation.—Category 246a. Duty free.

Tanned hides, without hair, sewn.—Category 190d (5). Duty, 70 lire per quintal.

Pepsine acidulated with hydrochloric acid in the form of extract.—Category 62. Duty, 120 lire per quintal.

Non-alcoholic perfumeries, placed in little paper bags, are classified under "non-alcoholic perfumeries," the weight of the paper bags being included with the goods.

Vessels of celluloid for centrifugal machines intended for the bleaching of thread.—Category 226n. Duty, 11 lire per quintal.

UNITED STATES.

Recent Customs Decisions.

The following decisions affecting the classification of articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the United States Customs authorities:—

An article called "opium ashes," containing 6·02 per cent. of morphia, is dutiable at the rate of 10 dollars per pound under Schedule A. (T. I., 121).

Bauxite, ground or pulverised, is held to be free of duty under T. I., 604, on the ground of retaining its commercial designation irrespective of the condition in which it may be imported.

On the exportation of refined stearin, manufactured wholly from imported crude stearin, a drawback will be allowed of the duties paid upon a quantity of the imported material equal to the net weight of the exported article, less the legal retention of 10 per cent.

Bromo-fluoresceic acid, a derivative of coal tar, and itself a coal-tar colour, used in imparting colours to various fabrics, is classified under paragraph 82 (T. I., new), and dutiable at the rate of 35 per cent. *ad valorem*.

Ferro-silicon, ordinary pig-iron containing about 10 per cent. of silicon, and used in mixing with low grades of pig-iron to increase the percentage of silicon, and thereby strengthen the product, is dutiable as pig-iron at the rate of three-tenths of a cent per pound.

Fruit-juices, when containing over 20 per cent. of alcohol, should be classified under Schedule H. (T. I., 312), as "compounds or preparations of which distilled spirits are a component part of chief value," and subjected to a duty of 2 dollars per gallon.

So-called "jasmine water" is to be classified as a medicinal water under T. I., 93, and pay duty at the rate of 25 per cent. *ad valorem*.

Certain iron oxide used as a colour or paint to be classified under T. I., 87, for "colours and paints," and dutiable at the rate of 25 per cent. *ad valorem*.

Sylvénite is free as a manure salt.

Indian red (earth paint) is dutiable as colours at the rate of 25 per cent. *ad valorem*.

Albuminised paper is dutiable at 25 per cent. as paper not otherwise provided for.

"Chlorophyl" is dutiable as a vegetable colour at the rate of 25 per cent. *ad valorem*.

So-called creolen and ichthyol, products obtained from the distillations of English coal, are dutiable at the rate of 25 per cent. *ad valorem* as chemical compounds not otherwise provided for under T. I., 92.

So-called "primulin," a colour derived from coal tar, is dutiable under T. I., 82, at the rate of 35 per cent. *ad valorem*.

Certain Peruvian bark, not being in a ground state, but advanced in manufacture for the purpose of developing the alkaloid principle, is dutiable at the rate of 10 per cent. *ad valorem* under T. 1., 94.

Cherry juice, which is obtained from fruit in its natural condition, and which is simply charged with spirit to prevent fermentation, shall be classed under the special provision for "fruit juice," at the duty of 20 per cent. *ad valorem*.

Merchandise found, upon chemical analysis, to consist of a mixture of ground shellac and a ground turpentine gum, forming a fabricated mixture intended to take the place of pure ground shellac, was returned for duty as a manufactured article unenumerated under section 2513, Act of March 3, 1883, at the rate of 20 per cent. *ad valorem*.

TRINIDAD.

Tariff of Import Duties.

The following is a statement of the rates of import duty now levied in the island of Trinidad:—

Articles.		Rates of Duty.
		£ s. d.
Oleomargarine, butterine, or any preparation of fat other than lard or ghee.....	Lb.	0 0 1
Gunpowder.....	"	0 0 7
Earthen and glass-ware, for every 100l. of value.....		4 0 0
Leather manufactures, for every 100l. of value.....		4 0 0
Methylated spirits, admitted as such by the Collector of Customs.....	Lb.	0 1 6
All other spirits, strong waters, liqueurs, and cordials if not exceeding the strength of proof as ascertained by Sykes' hydrometer, except tinctures admitted by the Collector of Customs as being for medicinal purposes only, which shall be charged with duty at the rate payable by goods unenumerated..	Liquid gall.	0 9 0
And for every degree of strength beyond that specified above an additional duty of 1d. the liquid gallon.		
Oil, creosote, for every 100l. of value.....		4 0 0
Do., coconut.....	Gallon	0 1 0
Do., petroleum.....	"	0 1 0
Do., all other kinds.....	"	0 1 0
Oil meal.....	100 lb.	0 1 0
Opium, including all goods, wares, or merchandise mixed or saturated with opium or with any preparation thereof, except tincture of opium, admitted by the Collector of Customs as being for medicinal purposes only, which shall be charged with duty at the rate payable by goods unenumerated..	Lb.	0 10 0
Soap.....	100 lb.	0 2 1
All other goods, for every 100l. of value.....		4 0 0

Exemptions.—Arrowroot; bark; bones and horns, unmanufactured; charcoal; lime; manures; and starch.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

THE WEIGHTS AND MEASURES ACT, 1889.

A memorandum on the Weights and Measures Act, 1889, prepared by the Board of Trade, appears in the September number of the Board of Trade Journal, p. 322.

THE MANUFACTURING INDUSTRIES OF BRITISH INDIA.

The following information is extracted from the statement exhibiting the moral and material progress and

condition of India during the year 1887—88, ordered by the House of Commons to be printed on the 16th August last:—

The domestic industries of India, such as pottery and brass and iron work, continue to be practised after ancient methods all over India, but are giving way before the products of British factories.

The produce of the paper mills, of which there were four in the Bombay Presidency, and five in other parts of India, had increased in value from Rx. 177,995 in 1885 to Rx. 258,645 in 1887. There were 19 breweries at work, of which three were opened in 1887—88. They produced during the year 4,860,000 gallons of beer and porter.

Among other "large industries" which are shown in the Indian returns for 1887—88 may be mentioned:—

Soup factories.....	2
Tanneries (large).....	7
Sugar factories (large).....	9
Cutch and lac factories.....	50
Oil mills.....	28
Cement factory.....	1
Bone manure factories.....	2

It is reported that attempts are being made to improve the quality of the silk by inducing the natives to take more care of their worms, and by the judicious use of European mulberry seeds. With this view European seed has been distributed, and foreign cocoons have been introduced. Some experiments are also said to have been made successfully to get over the difficulty of spinning tussar by means of a chemical process.

Besides the large *sugar* mills at Cossipore, there are said to be 170 smaller factories in the district, at which sugar is refined according to the native method. In Jessore, sugar is manufactured all over the district. There is one manufactory at Kotechandpore, where 14,833 maunds of refined sugar were produced. It is observed, however, that the industry has declined since foreign sugar has been brought into the market.

There was a decrease in the manufacture of *salt* in all the Orissa districts except Pooree, where the out-turn increased from 5,000 maunds in the previous year, when the greater number of the manufacturers resigned their licences through objection to being placed under the Madras rules, to over 80,000 maunds, the manufacturers having resumed business. In Balasore the industry is fast dying out, owing to the competition of Liverpool salt.

The *brass* and *copper* manufactures of the Punjab depend for the raw material on importations, chiefly from Europe. In former times copper used to come from Cabul, but this has entirely ceased; and Chinese zinc has long been driven out of the market by the European spelter. Various copper and zinc ores exist in the Kulu Hills and other parts of the Himalayas, but the imported copper and brass are so cheap that there is no present hope of those ores being worked. The most noticeable feature in the more recent developments of the industry is its concentration in certain towns, which have acquired a reputation for the quality of their goods.

In May in conclusion he noticed that a native engineer, a man of considerable means and intelligence, has opened a *brass* factory at Moheshgunge, and it is said that the manufacture and trade in brass vessels are brisk.

There are various manufactories in the North-West Provinces and Oudh, of which the principal are 2,210 indigo factories, employing 66,530 hands.

There were three factories for the manufacture of *sugar*, one at Aska in Ganjam, and two in South Arcot at Nellikuppam and Iravallepet. The last-named factory was not worked during the year. The Behea sugar-cane mill was largely used in the western taluks of Bellary.

From Karachi it is reported that the introduction of *bone crushing* machinery has rendered it possible for ship-owners to convey bones at ordinary cargo rates, and that this fact may be expected to have a favourable influence on the largely expanding trade in the export of bones.

The *Reay paper mill* at Mundhwa, near Poona, with a capital of Rx. 50,000, commenced work during the year. It afforded employment to 180 persons on an average, and produced 130 tons of paper, valued at Rs. 5,460.

THE SALE OF MARGARINE IN RUSSIA.

A despatch, dated the 6th August last, has been received at the Foreign Office from Sir R. B. D. Morier, Her Majesty's Ambassador at St. Petersburg, enclosing a translation by Mr. Michell of a statement in the *Moscow Gazette*, describing the modifications adopted by the Council of the Empire in the scheme for the sale of margarine in Russia, which has now been returned to the Minister of Domains for further elaboration. The following is a copy of the translation in question:—

The Council of the Empire has considerably modified the scheme submitted to it by the Minister of Imperial Domains for the sale of margarine in Russia. The chief modifications consist in the prohibition to mix genuine butter with margarine; in the appointment of Government inspectors who will exercise strict supervision over margarine manufactories. Moreover, these manufactories must wind up their business in the course of the next five years, after which they will finally close, and permission to establish new margarine works will not be granted. The project has been returned with the above modifications to the Minister of the Domain for further elaboration, which, when completed, will be again discussed by the Council in its full assembly.

THE OLEOMARGARINE LAW IN THE UNITED STATES.

In July 1886 Congress passed an Act which was approved by the President August 2nd, imposing a tax on the manufacture, sale, importation and exportation of oleomargarine, and placing the whole matter under the control of the Commissioner of Internal Revenue. The system followed is very similar to that pursued in collecting the tax on tobacco.

The regulations to carry out the law have lately been revised, and go into effect September 1st. A brief résumé of the law and regulations may not be uninteresting at this time.

Section 8 of this Act provides: "That upon oleomargarine which shall be manufactured and sold, or removed for consumption or use, there shall be assessed and collected a tax of two cents per pound, to be paid by the manufacturer thereof; and any fractional part of a pound in a package shall be taxed as a pound. The tax levied by this section shall be represented by coupon stamps; and the provisions of existing laws governing the engraving, issue, sale, accountability, effacement, and destruction of stamps relating to tobacco and snuff, as far as applicable, are hereby made to apply to stamps provided for by this section."

Section 3 imposes upon manufacturers and dealers in oleomargarine special taxes, as follows:—

"Manufacturers of oleomargarine shall pay six hundred dollars. Every person who manufactures oleomargarine for sale shall be deemed a manufacturer of oleomargarine."

"Wholesale dealers in oleomargarine shall pay four hundred and eighty dollars. Every person who sells or offers for sale oleomargarine in the original manufacturer's packages shall be deemed a wholesale dealer in oleomargarine. But any manufacturer of oleomargarine who has given the required bond and paid the special tax, and who sells only oleomargarine of his own production, at the place of manufacture, in the original packages to which the tax-paid stamps are affixed, shall not be required to pay the special tax of a wholesale dealer in oleomargarine on account of such sales."

"Retail dealers in oleomargarine shall pay forty-eight dollars. Every person who sells oleomargarine in less quantities than ten pounds at one time shall be regarded as a retail dealer in oleomargarine."

Every manufacturer of oleomargarine is compelled by the regulations, in compliance with section 5 of the law, "before commencing business, and on the first day of May of each year before continuing business, to file with the collector of the district in which his factory is located a notice," on a prescribed form, stating the location, the character of the machinery and appliances used for manufacturing, the total capacity, in pounds, for producing oleomargarine each day of 24 hours, in his factory; to give "a

bond in an amount to be fixed by the collector, of not less than 5,000 dols., with two or more sureties satisfactory to him; and to file an inventory of all the materials that enter into the manufacture of oleomargarine, including all materials in process of manufacture, all finished products, and all other materials owned by him on that date." (See Forms 213, 214, and 215.)

He also keeps a book, which is open to the inspection of every Internal Revenue officer and agent, showing the amount of all materials used each day of the month in the manufacture of oleomargarine and all products, whether of oleomargarine, stearin, or other product; and makes monthly returns from his book on a prescribed form.

This monthly return, made out in duplicate (the original is placed on file in the office of the collector of the district in which the factory is situated, the duplicate is forwarded to the central office at Washington), shows the quantity and kind of material used for the production of oleomargarine, and the quantity of oleomargarine produced each day of the month; and also the quantity and kind of materials otherwise used during the month. It also gives in detail the quantity of oleomargarine sold, removed, or destroyed on each day of the month, with the serial number of the package, the name, place of business and residence of the persons to whom sold or consigned; together with a recapitulation showing the aggregate quantity on hand at the beginning of the month, the quantity produced, the quantity sold and removed, including losses, and the quantity on hand at the close of the month. The quantities of oleomargarine are stated in taxable pounds.

It sometimes happens that tax-paid oleomargarine is returned to the manufacturer. In this case he enters on his book and monthly return the serial number of the packages and the date when returned. In case it is worked over, it is credited on the material account, and if it is sold again intact, the date of the second withdrawal, and all other particulars, including the name and address of the new purchaser, are entered, in *red ink*, on his books and returns. (See Book, Form 60 and Form 216.)

Wholesale dealers are also required to keep a book and make a monthly return, showing in detail the quantity of oleomargarine received by them direct from the manufacturers, giving the date, from whom and whence received, by what manufacturer produced, together with the serial number of packages and number of taxable pounds; also the quantity of oleomargarine disposed of by them, with date, serial numbers of packages, taxable pounds, by what manufacturer produced, to whom sold or delivered, with name and address; also the quantity received from other wholesale dealers, the quantity disposed of to other wholesale dealers and the quantity disposed of to persons not known to be wholesale dealers. Oleomargarine disposed of by a wholesale dealer to himself as a retail dealer or consumer is included in such statements. (Book, Form 61 and Form 217.) Retail dealers are not required to keep books or make monthly returns.

Oleomargarine is put up in wooden packages, either solid packed, in rolls or in prints; and before removal from the factory is branded or stencilled with the serial number of the package, corresponding to the number on the stamp, the word "Oleomargarine," and the number of the factory and district: the packages also have a cautionary notice or label pasted on them. The stamp having been affixed is immediately cancelled. The face value of the stamp represents the tax on the number of taxable pounds of oleomargarine contained in the package.

The stamps are engraved and bound in book form, containing 200 stamps, each of the denominations 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 pounds. Attached to each stamp are nine coupons, each coupon representing one pound. The tax-paid stamp must be signed by the collector and have written thereon the date of the payment of the tax, the number of pounds, the number of the factory, the serial number of the package, and the name of the person by whom or for whom it was cancelled.

"Retail dealers in oleomargarine must sell only from original stamped packages, in quantities not exceeding ten pounds, and shall pack the oleomargarine sold by them in suitable wooden or paper packages." (Section 6.) These

packages must have, besides the name and address of the dealer, the word "Oleomargarine," and the quantity in pounds contained therein, written or printed upon them in letters not less than $\frac{1}{4}$ inch square, and must be so placed as to be plainly visible to the purchaser at the time of delivery to him.

The law makes provisions for testing substances suspected of being oleomargarine, and also "whether any substance made in imitation or semblance of butter, and intended for human consumption, contains ingredients deleterious to the public health." No samples, however, have ever been submitted under the latter clause.

Oleomargarine imported from foreign countries is not required to have the Internal Revenue stamps affixed thereto and cancelled unless it is withdrawn from the Custom house for consumption or sale in the United States.

Manufacturers of oleomargarine may export their product and be allowed credit for the taxable quantity exported according to law. The regulations go into minute details on the different steps to be pursued. (See Regulations, Series 7, No. 9, Revised, U.S. Internal Revenue.)

The law imposes heavy penalties for violations of its provisions. (See sections 4, 6, 7, 10, 11, 12, 13, 15, 17, 18, Act of August 2, 1886.)

From the manufacturers' and wholesale dealers' monthly returns a list is made, at the Washington Office, of the names and addresses of the different purchasers in each collection district, which list is sent to the several collectors of Internal Revenue. By this means a collector can verify his list of wholesale and retail dealers who have paid the special tax, and investigate and ascertain who may be dealers without having paid the special tax required by law.

The greatest trouble, in enforcing the national law and collecting the special taxes, has been met with in those States where the State law contains prohibitory features, which are enforced by arresting and imprisoning all dealers who have paid the internal revenue tax and whose names appear, therefore, in the collector's book, which is open to the public inspection: although beyond that these State officers do not appear to go. These State laws likewise prohibit the manufacture or sale of cheese containing foreign fats, and the use of oleomargarine at hotels, restaurants, or boarding houses; features of their laws which do not seem to be enforced. The consequence has been that dealers have abandoned the open sale of oleomargarine but continue to supply their customers, by placing their orders directly with the manufacturers, by whom the oleomargarine is shipped to the customers' residence, the dealers thus acting as the manufacturers' agents. The consumer of 10 lb. or more of oleomargarine has therefore no trouble in obtaining his weekly supply direct from the factory, but the large class of people in these prohibition States who want only a few pounds at a time are denied that privilege and are compelled to pay a great deal higher price for the lowest grades of poor rancid butter.

The following statements, showing the number of manufacturers, wholesale and retail dealers, from October 31, 1886, when the law first went into effect, to April 30, 1889, the end of the last special-tax year, engaged in the business each year; the quantity of oleomargarine produced, withdrawn from factories tax-paid, lost or destroyed, and exported, during the same period; and the receipts during the last two years, are compiled from the reports of the Commissioner of Internal Revenue:—

STATEMENT SHOWING NUMBER OF MANUFACTURERS AND DEALERS, AND OF THE QUANTITY OF OLEOMARGARINE PRODUCED IN THE UNITED STATES.

Special-tax Year.	Manu- facturers.	Wholesale Dealers.	Retail Dealers.	Quantity Produced.	Quantity withdrawn Tax-paid.	Lost or Destroyed.	Quantity Exported.	On Hand.
Oct. 31, 1886, to April 30, 1887	32	235	3,929	18,494,177	17,672,507	42,750	535,308	181,090 Nov. 1, 1886 2,531 April 30, 1887
May 1, 1887, to April 30, 1888	29	154	3,279	32,270,532	30,812,624	17,015	1,383,675	57,188 April 30, 1888
May 1, 1888, to April 30, 1889	23	169	3,906	37,409,064	34,981,909	2,917	2,065,849	358,398 April 30, 1889

STATEMENT OF THE RECEIPTS FROM OLEOMARGARINE DURING THE FISCAL YEARS ENDED JUNE 30, 1888 AND 1889.

Objects of Taxation.	Receipts during Fiscal Year.		Increase.	Decrease.
	1888.	1889.		
OLEOMARGARINE.	Dols.	Dols.	Dols.	Dols.
Oleomargarine, domestic and imported.....	653,355'10	677,302'40	23,947'30	..
Manufacturers of oleomargarine (special tax).....	17,150'00	12,400'00	..	4,750'00
Retail dealers in oleomargarine (special tax).....	123,258'54	134,631'51	7,372'97	..
Wholesale dealers in oleomargarine (special tax).....	79,376'24	73,914'00	3,537'76	..
Total.....	864,139'88	894,247'91	30,108'03	4,750'00

A peculiar but natural tendency, owing to the high rates of the special taxes, has been noted of dealers paying their special taxes for the last six months of the special tax year, viz., from November to May, and not for the whole year. In other words, during the spring and summer months, when dairy butter is cheaper than oleomargarine, there is no profit in selling the latter. The small manufacturer has been driven out of the business, for the reason that he could not produce enough to make it profitable with his limited plant.

It will be seen from the above statement that although the number of factories have been reduced from 32, when the law first went into effect, to 23 on April 30th last, the

domestic consumption and the exportation of oleomargarine has steadily increased. An average monthly increase of one-third of a million pounds in domestic consumption in the past year would seem to indicate that, notwithstanding the false impressions that were widely disseminated about oleomargarine, it has attained its permanent place among an increasing class of consumers as a cheap and wholesome article of food.

By the system pursued each manufacturer's package of oleomargarine can be traced from the time it leaves the factory duly stamped, branded, and labelled to the hands of the wholesale dealer, till it reaches the retail dealer and often the consumer. The retail dealers incur such heavy

penalties if they do not properly brand their packages with the word "oleomargarine," that the fraudulent sale of oleomargarine for butter, *i.e.*, at butter prices, is very limited.

A description of the American methods of manufacturing oleomargarine was printed in the Annual Report of the

Commissioner of Internal Revenue for 1888, p. clxi. (Abst. Jour. Soc. Chem. Ind. Vol. VIII., p. 408).

The following table, taken from the same report, p. clx., shows the extremes in composition of oleomargarine and its ingredients:—

EXTREMES OF COMPOSITION OF SAMPLES OF OLEOMARGARINE AND INGREDIENTS.

Oleomargarine.	Specific Gravity at 40° C.	Saponification Equivalent.	Vol. N ₁₀ NaOH for 2.5 Grms.	Ingredients.	Specific Gravity at 40° C.	Saponification Equivalent.	Vol. N ₁₀ NaOH for 2.5 Grms.

—U.S. Department of Internal Revenue.

THE ADULTERATION OF BUTTER AND LARD IN THE UNITED STATES.

A report to the Foreign Office, dated the 23rd August last, has been received from Captain W. F. Seagrave, Her Majesty's Consul at Baltimore, on the subject of the adulteration of butter and lard. The following is an extract from the report in question:—

Under the Act of Congress of August 1886 butter is defined as a "food product usually known as butter, and which is made exclusively from milk or cream, or both, and with or without salt or colouring matter."

Under the same Act, oleomargarine is defined as "certain manufactured substances, extracts, mixtures, and compounds, including such mixtures and compounds with butter, whenever made in imitation or semblance of butter. And when so calculated to be sold as or for butter."

Though the above may not be the strict chemical definition of oleomargarine, it is the legal one, and holds good throughout the United States, and for overlooking its provisions, certain members of a firm in the city of Baltimore had, not long ago, to serve a term of imprisonment.

Special attention, therefore, is called to it, because the dairymaid, who adds a little cotton-seed oil to her churning to make the butter come more quickly, is probably not aware that she is making oleomargarine, and infringing the law.

The analytic descriptions of oleomargarine in this part of the country, and which, anterior to present legislation, passed current as butter, are various.

In one case, three or four pounds of black grease drippings neatly covered with a layer of fairly good butter two or three inches deep, whether kneaded together or not, is now legally defined as oleomargarine.

Another sample contained 40 per cent. of tallow mixed with a similar preparation to that above described.

Another sample consisted of 50 per cent. of butter made up with water, casein, and boiled starch.

These various compounds, which now pass legally as oleomargarine, find their way from small country dairies to village shopkeepers, who take them in exchange for groceries, and so soon as they have accumulated two or three barrels of this stuff they despatch it to the large cities

and place it on the market, where it is readily disposed of for cooking. It is said that in the Western States this stuff undergoes some peculiar process of manipulation, and is turned into what is called "ladle-packed butter."

In these Eastern States, however, the manipulation of this class of so-called butter, even with the aid of chemicals, has not as yet proved a financial success. It was no doubt in referring to this so-called "ladle-packed butter" that the president of an agricultural college in the West, addressing an association of dairy farmers, described it in the picturesque and figurative language of the country as "a butter 40 per cent. below zero for badness, of a grizzly, white, brindled, streaked, cheesy sort, old enough to vote, and strong enough to stand alone under the influence of ice, and which had a flavour of its own, which it generously imparted to everything which it touched. To mention oleomargarine with so-called bakers' butter was, he said, an insult to the dead animal which furnishes the fat from which the oleomargarine is made." Yet there is plenty of this class of butter in every large city.

"Ladle-packed butter" is in the Eastern States presumably genuine butter which has been collected in small parcels from different farmers along a collector's route. At the end of his journey the collector mixes the different parcels together, gives it a uniform colour, and then packs it away in tubs, which are despatched to the commission merchant.

No doubt the packer mixes a small percentage of oleomargarine with his purchases, perhaps 10 per cent., though, if detected, he will most probably assure you that it got in accidentally at some farmhouse on his route.

If, however, sworn evidence is worth anything, there is little "ladle-packed butter" sold in the market in this State which does not contain about 10 per cent. of foreign fat, whether cotton-seed oil, or tallow, or stearin, or real oleomargarine.

In place of the old-fashioned churn, which is rapidly disappearing, the modern "creamery" is being everywhere established.

These creameries are, in other words, co-operative dairies where, instead of the antiquated methods, steam supplies the place of manual labour, and economy of manufacture is the prevailing characteristic, combined with care, cleanliness, and dividends.

The number of these creameries is already very great, and is daily increasing.

It is to them that the trade look for their supply of table butter, and the general verdict is that they produce a good article.

The adulteration of lard has assumed such huge proportions as to call for a special Act of Congress in order to protect the legitimate manufacturer and trader.

The new legislation assumes to have been based on sanitary grounds, but the real issue is the commercial injury done to the bona fide trader through wholesale adulteration. And no doubt it was high time that legal protection should have been extended to the latter.

About seven-eighths of the lard exported from the United States is termed "Western refined lard," or "compound lard," or "prime steam lard," and appears, according to the evidence laid before a committee of the United States Senate, to be compounded in the following manner. It was stated that the "packers went on until they began to put in the whole hog; head, trimmings, offal, everything went in making one 'straight brand,' known as 'steam lard.' Now the great packing houses in the West do not waste their time in cleaning the offal and pannich; they just throw everything into the tank—entrails, head, feet, and all."

The lard tank in a packing house is to-day a sort of receptacle for everything in the shape of grease on the establishment.

There is no longer any such article as No. 1 lard; everything goes in and it all forms "prime steam lard." For such lard, of course, some process of refining is necessary. For this purpose it is, when received from the packers, put into a large tank and open steam turned on, and the contents of the tank boiled for an hour or two, when it is allowed to settle, and the impure scum is skimmed off, and the skimmed lot allowed to stand for 10 hours, when, as it is alleged, all odour has disappeared.

One witness declared that regular refined lard contains approximately 50 to 75 per cent. of prime steam lard, 15 to 25 per cent. of pure cotton-seed oil, and about 10 per cent. of beef fat, or oleo, or stearin, the proportions being occasionally varied according to temperature and destination.

It is asserted that quite seven-eighths of the lard now sold in the United States is compounded after the above prescription.

Watered lard is by no means a novelty, about 30 per cent. of water is the limit that can be combined with lard without causing it to "spit" when used in cooking.

Cotton-seed oil is, as is expressed by its name, an oil pressed from cotton seed. The crude oil is of a red or even darker colour. It is refined by agitating crude oil with caustic soda, or, by another process, it is boiled with a solution of bleaching powder and subsequently agitated with sulphuric acid. The refined cotton-seed oil is of a pale-straw colour or almost white.

It does duty all over the United States as salad oil, and often as genuine olive oil; it is an extremely convenient product for the adulteration of butter, cheese, and lard, and is largely used for such purposes. Of course it is cheaper than any of the products with which it is combined, otherwise it is safe to say that valuable as may be its qualities as a food product it would never be used as an adulterant.

STATISTICS.

NOTES ON THE GERMAN DRUG TRADE.

(From Messrs. Gehe & Co.'s Semi-annual Circular.)

While German trade in general has had a fairly prosperous year in 1888, the drug and chemical industries have been touched by the general improvement to a very slight extent only. The imports of articles for use of the chemical industry and of pharmacy show a total of 243 millions of marks in 1888, against 219 millions in 1887, *i.e.*, an increase of 24 millions of marks; and if the average values of 1887 had been maintained there would have been exactly the same result, so that all the advances and declines of the

year have neutralised one another. The exports in the same category have been—in 1888, 236 millions of marks, against 226 millions in 1887. If the average prices of 1887 had also been maintained in this department, there would have been an increase of 17 millions, instead of 10 millions. The moral of these figures is that, while the Germans paid the same average prices for what they bought from abroad in 1888 as in 1887, they have had to sell their own products to the foreigner at a slight reduction.

MONTH ENDED 31ST AUGUST.

Articles.	Quantities.		Values.	
	1888.	1889.	1888.	1889.
Brass.....	6,196	9,882	£ 29,392	£ 39,984
Copper :—				
Unwrought	70,804	47,918	261,462	106,779
Wrought.....	5,463	35,389	24,969	100,099
Mixed metal	10,324	29,216	36,956	72,192
Hardware	250,916	220,984
Iron and steel.....	377,577	383,337	2,349,771	2,459,212
Lead	3,577	2,944	50,573	41,870
Plate wares....	32,756	31,782
Telegraphic wires	110,923	46,452
Tin	12,417	6,672	58,372	31,250
Zinc	18,447	4,421	12,849	3,945
Other articles .. Value £	150,504	171,914
Total value	3,381,848	3,329,443

EXPORTS OF DRUGS AND CHEMICALS FOR MONTH ENDED 31ST AUGUST.

Articles.	Quantities.		Values.	
	1888.	1889.	1888.	1889.
Alkali..... Cwt.	485,698	594,369	£ 122,961	£ 134,331
Bleaching materials ..	134,151	112,037	50,341	40,318
Chemical manure (% Foss)	..	38,714	168,787	174,359
Medicines..... Value £	78,750	74,036
Other articles	215,873	230,318
Total value	635,812	657,452

EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH ENDED 31ST AUGUST.

Articles.	Quantities.		Values.	
	1888.	1889.	1888.	1889.
Explosives:—			£	£
Gunpowder.... Lb.	943,700	604,600	24,363	14,212
Other kinds .. Value £	85,183	84,967
Candles..... Cwt.	606,209	1,231,003	12,067	21,547
Caoutchouc Value £	106,659	95,180
Cement..... Tons	53,420	38,404	165,195	74,504
Earthenware ... Value £	169,311	173,853
Stoneware "	94,72	12,037
Glass:—				
Plate..... Sq. Ft.	367,679	219,717	21,428	16,084
Flint..... Cwt.	11,849	8,402	23,936	19,488
Bottles..... "	79,543	75,251	33,728	35,295
Other kinds.... "	18,116	15,598	13,611	11,132
Leather:—				
Unwrought "	16,233	9,825	121,495	91,195
Wrought Value £	3,496	31,122
Seed oil..... Tons	5,765	4,057	114,927	110,986
Floor cloth Sq. Yds.	1,500,630	1,218,300	68,350	60,824
Painters' mate- rials Value £	128,839	121,339
Paper of all kinds. Cwt.	97,513	74,143	166,518	126,684
Rags..... Tons	4,143	4,069	32,149	31,947
Soap..... Cwt.	41,656	33,616	38,550	36,333
Total value of exports of miscellaneous articles	2,623,172	2,488,679

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 13,058. C. W. Guy. Evaporating apparatus. August 19.
 13,086. W. Burns. Arrangement for economising waste heat, and for consuming smoke from furnaces. August 19.
 13,212. R. Reichling. Evaporating apparatus, applicable for cooling or heating liquids, and for charging gases with vapours. August 20.
 13,239. W. A. Carlile. Blowers and exhausters. August 22.
 13,343. H. H. Lake.—From Kalle and Co., Germany. Improvements relating to the preparation of chemical compounds. August 22.
 13,363. J. Nicholas. Evaporating liquids. August 24.
 13,549. H. Bower. A certain new and useful process for facilitating chemical reactions. Complete Specification. August 27.
 13,584. J. R. Burgess and A. S. Williams. Pumps and pipes for chemical purposes and the like. August 28.
 13,598. H. McPhail, E. Simpson, and C. H. Simpson. Method and apparatus for generating steam and evaporating various liquids. August 28.
 13,761. J. Wach. Improvements in thermostats and apparatus operated by differences in the thermal expansion of metals. Complete Specification. August 31.
 13,814. W. Young. Apparatus for boiling brine and the like under a vacuum. September 2.
 13,815. W. Young. Apparatus for boiling brine and the like under a low heat in vacuum. September 2.
 13,816. W. Young. Apparatus for boiling brine and the like in a vacuum. September 2.
 13,875. A. Brimetti. Freezing apparatus. September 3.
 13,925. A. Crosbie and H. J. Mitchell. Carboy hampers. September 4.
 13,929. W. Bergh. Centrifugal apparatus for separating fluids of different specific gravities. September 4.
 14,229. H. H. Lake.—From T. G. B. de Ferrari di G. B., Italy. Method and apparatus for burning petroleum, naphtha, and other fuel in boiler and other furnaces. September 9.
 14,338. C. A. Sahlström and J. C. Bromfield. Furnaces for burning liquid fuel. September 11.
 14,381. F. Brighman. Bunsen burners. September 12.
 14,416. F. Radcliffe. Furnaces for melting and other purposes. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

14,683. R. Free and H. J. Pierce. Thermometers. September 18.

15,563. J. L. Stevenson. Improved valve for Siemens' gas furnaces. September 4.

1889.

900. Fleming's Oil and Chemical Co., Lim., and G. H. Fenner. See Class XII.

3705. R. Hollingdrake. Chilled firebars for burning smoke in all kinds of furnaces. September 11.

7203. H. Roeske. Improvements in filters. September 18.

9975. A. J. Boulton.—From P. Varin. Filters. September 11.

10,251. T. Gentzen and A. Wegener. Filters. August 28.

10,288. H. H. Lake.—From O. B. Peck. See Class X.

10,955. J. Johnston. Apparatus for heating, drying, &c. September 11.

11,466. H. H. Chapman.—From J. Donaldson. Attachment for indicating pressures and levels of fluids in vessels. September 4.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

13,129. C. B. Harris. An improved method of making incandescing elements for gas burners. Complete Specification. August 20.

13,143. G. Bower. Means or apparatus for carburetting air or gas. August 20.

13,195. W. F. K. Stock. Improvements in the manufacture of coal gas. August 20.

13,390. W. Fritsch. Improvements in coke ovens. August 24.

13,402. T. Blandford. Increasing the heating properties of fuel in furnaces for generating steam or heating and melting metals or other minerals. August 26.

13,436. P. Tyrer and L. Breeze. Heating water or other liquids noiselessly by the aid of direct contact of steam, to be called "Breeze's silent water-heater by steam." August 26.

13,653. W. P. Thompson.—From P. Marx and M. Notkin, Russia. A new or improved process for the purification of mineral oils, and for producing alcohol. August 29.

13,712. R. D. Bowman. Improved process for the production of oxygen gas. August 30.

13,763. E. Tatham. An improved gas, usable as an explosive, and, in admixture with other gases, as an illuminating and heating gas. Complete Specification. August 31.

13,933. R. B. Helliwell. Improvements in firelighters. September 4.

13,999. O. Brown.—From G. A. Goyder, Australia. Improvements in the manufacture of gas adapted for use in motor engines and otherwise, and in apparatus applicable for employment in such manufacture. September 4.

14,031. J. Loves. Improvements in apparatus for carburetting gas or air. September 4.

14,060. F. N. Mackay. Improvements in separating tar and ammonia from gases, and in apparatus therefor. September 6.

14,287. M. A. Morse. Improvements relating to the manufacture of gas, and to apparatus therefor. Complete Specification. September 10.

14,291. S. Pitt.—From C. B. Harris, United States. Apparatus for the manufacture of gas. Complete Specification. September 10.

14,424. H. Williams. Improvements in the manufacture of the gas commonly styled "water-gas," and in apparatus employed in such manufacture. September 13.

14,425. H. Williams. Improvements in carburetting gas, and in apparatus therefor. September 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

8559. The Gas Patents Syndicate, Ltd. Apparatus for the manufacture of gas. September 18.

14,105. W. T. Sugg. Improved mode of lighting by gas. September 4.

15,393. H. H. Lake.—From F. Honnay. Preparation of tar for use in the manufacture of artificial fuel. September 11.

15,410. L. W. Leeds and The Leeds Patent Floor Warming Stove Co., Ltd. Stoves for burning gas or liquid fuel. September 11.

1889.

90. S. G. Rhodes. Fireballs for use as artificial fuel. August 28.

1414. L'Agence Maritime Anglaise, Ltd.—From C. Audony. Apparatus for manufacturing artificial fuel blocks. August 28.

1637. J. Ewing. Combustion and economy of fuel, and bar preservation. September 11.

6659. J. von Langer and L. Cooper. Manufacture of water-gas. September 18.

7044. A. Harkness and W. T. Harkness. Method and apparatus for effecting the complete combustion of fuel in heating furnaces, and the abatement of smoke nuisance. September 18.

11,610. W. Hubbard. Manufacture of compressed fuel blocks. August 28.

11,899. C. Huelser.—From G. Kassner. Preparing plumbates of calcium, barium, and strontium, and employing the same for oxidising purposes and for producing oxygen, &c. September 18.

12,092. A. Weber. Coke ovens or furnaces. September 4.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATION.

13,861. A. H. Allen and W. W. Staveley. Improvements in the treatment of oils to be used for creosoting, pickling, or preserving timber. September 3.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

13,217. H. H. Lake.—From A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. August 20.

13,266. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brüning, Germany. An improved manufacture of basic colouring matters. August 22.

13,299. J. H. Chaudet. Improvements in and relating to the preparation or combination of aniline dyes and other like substances, and their application to dyeing animal or vegetable textile materials. August 23.

13,386. The Clayton Aniline Co., Ltd., H. Bull, and J. Hall. Improvements in the manufacture or production of colouring matters. August 24.

13,558. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in and connected with the manufacture of colouring matters suitable for dyeing and printing without the use of a mordant. August 27.

13,665. B. Willcox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in or connected with the manufacture and production of colouring matters or dyestuffs. August 29.

13,710. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brüning, Germany. Production of azo-colouring matters from dioxynaphthabimmonosulphonates. August 30.

14,207. The Clayton Aniline Co., Ltd., P. Brunner, and J. Hall. Improvements in the manufacture and production of colouring matters or dyestuffs. September 9.

14,222. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture and production of diazo-colouring matters. September 9.

14,230. B. Willecox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture, production, and application of colouring matters. September 9.

14,294. H. H. Leigh.—From R. G. Williams, United States. Improvements in dye colours. September 10.

14,303. A. G. Green and T. A. Lawson. The production of new azo-colouring matters. September 10.

14,304. A. G. Green and T. A. Lawson. The production of new azo-colouring matters. September 10.

14,388. R. Ashton. Improvements in the method of preparing colours for making writing inks. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,121. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of derivatives of alizarin-green for dyeing and printing. August 28.

15,258. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of diazo dyestuffs. August 28.

15,259. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of the sulpho-acids of a red basic naphthaline dyestuff. September 18.

15,260. B. Willecox.—From The Farbenfabriken vorm. F. Bayer and Co. Production of colouring matters from alizarin mono-sulpho acids. August 28.

15,849. A. G. Green. Manufacture of a β -naphthylamine sulphonic acid. September 18.

16,325. O. Inray.—From The Farbwerke vorm. Meister, Lucius, and Brünig. Manufacture of induline colouring matters soluble in water. September 18.

16,393. C. D. Abel.—From The Farbwerke vorm. Meister, Lucius, and Brünig. Production of colouring matters resembling the indulines. September 18.

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

13,127. W. Latimer. Improvements in and relating to a new and useful fibre produced from the leaves of needles of *Pinus Australis* and other coniferous trees. Complete Specification. August 20.

13,173. J. Holden and J. R. Jepson. Improvements in or relating to the manufacture of felt. Complete Specification. August 20.

13,237. E. Ogden. Improvements in means for ornamenting textile fabrics. August 22.

13,626. A. Ambler, S. Ambler, and F. Ambler. Improvements in the cleansing or washing of wool and like animal fibres, and in apparatus employed therein. August 29.

14,316. J. Grumbut, E. Gonty, and F. B. Gonty. A new or improved process for waterproofing materials or fabrics and the like. Complete Specification. September 11.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

13,299. J. H. Chaudet. See Class IV.

13,370. J. Murgatroyd. A new mordant for dyeing black and other colours. August 24.

14,246. A. Ashworth. Improvements in the production of an indigo vat. September 10.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

13,264. J. Farmer. Improvements in or connected with the manufacture of acetic acid, and in apparatus therefor. August 22.

13,398. F. M. Lyte. Process for the separation of sodic chloride from magnesic or calcic chloride. August 24.

13,543. R. B. Grüneberg. Improvements in apparatus for absorbing and rendering harmless the waste gases from the "Chance" sulphur recovery process. August 27.

13,575. M. N. D'Andria. Improvements in treating liquid acid residues containing iron to obtain products therefrom. August 28.

13,697. H. Grüneberg, H. Fleming, and W. Siepermann. Improvements in the preparation of cyanogen alkalis, and in apparatus therefor. August 30.

13,726. E. de Cuyper. An improved process for recovering valuable substances from the mother-liquor resulting from treatment of copper ores. August 30.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,236. J. Werber and G. Hendry. Rectification and concentration of acetic acid, and apparatus therefor. August 28.

14,333. M. Camon. Manufacture of acetic acid. August 28.

14,977. H. H. Leigh.—From F. T. Roniguières. Manufacture of caustic alkalis and their carbonates by means of their chlorides; applicable also to the dissociation of alloyed metals. September 4.

15,063. H. W. Deacon and F. Harter. Manufacture of chlorine. August 28.

15,173. C. F. Claus. Obtaining carbonic acid gas from mixtures with other gases, obtaining and utilising the residual gases, and production of carbonates of ammonia. August 28.

15,624. G. H. Bolton and J. R. Wyld. Concentrating caustic alkali and other liquors by multiple effect or Yaryan plant for preventing deposit in the tubes. September 18.

16,166. T. Turner. Treating waste liquors containing chloride of iron or chloride of iron and hydrochloric acid, and extracting therefrom oxide of iron and hydrochloric acid. August 28.

16,349. G. E. Davis. Construction of ammonia stills. September 18.

1889.

3338. A. Collingridge.—From V. Cornet and A. Jones. Manufacture of common salt, and apparatus therefor. August 28.

6118. H. H. Lake.—From J. L. Alberger, H. Williams, and L. R. Alberger. Apparatus for the manufacture of salt. September 11.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

13,036. A. Taylor. Improvements in the method of and apparatus for building up the inside of kilns for burning enamelled bricks and tiles. August 19.

13,051. J. Peirce and T. F. Luther. Enamelled metallic tessellated plates for hearths and floors. August 19.

13,128. A. G. Neville. Improvements in and relating to the construction of glass pots. Complete Specification. August 20.

13,262. H. Dudley-Cooper and J. Selby. An improved construction of connexions for glass or porcelain lined metal tubing. August 22.

13,197. J. Ferguson. Improvements in utilising and ornamenting rolled cathodal and all other rolled glass, and machinery for same. August 27.

13,577. M. Sugar. — From C. Lasalle and C. Mautter, France. Improvements in treating or ornamenting glass and glass-ware. August 28.

13,611. J. B. Goes and T. Evans. Annealing ovens. August 29.

13,880. M. W. Griswold and W. B. Atterbury. Improvements in the manufacture of sheet or window glass. Complete Specification. September 3.

13,994. S. Washington. Improvements in finishing glass-ware, and in apparatus therefor. September 4.

14,156. The Coalport China Company (J. Rose and Co.) and T. J. Bott. Improvements in ornamenting china, earthenware, glass and like ware. September 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,990. J. Colton and J. H. Lambert. Glass mosaic work. August 28.

15,485. J. Armstrong. Method of rolling glass, and apparatus therefor. September 4.

15,944. A. D. Brogan and A. M. Malloch. Apparatus for imparting surface ornamentation to glass. September 18.

1889.

3673. H. M. Ashley. Apparatus for manufacturing bottles and other hollow glass-ware. September 4.

3686. H. M. Ashley. Machinery for making bottles and like hollow glass-ware. September 4.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

13,050. T. Hyatt. Improvements in pavements and paving materials. August 19.

13,749. H. Aitken. Improvements in treating timber, more particularly such timber as is used for mining purposes. August 31.

13,888. P. Champion. An improved process and apparatus for the manufacture of "boiled plaster of Paris." September 3.

13,937. B. Mertelmeyer. Process and apparatus for producing an airless substance for artificial stones. September 4.

13,979. W. Darling. Improvements in and relating to the calcining of carbonaceous minerals for cements and other purposes. September 4.

14,281. S. Jørgensen. Improvements in the process of heating cements and hydraulic lime. Complete Specification. September 10.

14,343. W. A. Dixon. Improvements in the preparation of wood paving for streets. September 11.

14,515. A. J. Paris. Improvements in fireproof plaster cloths for ceilings, walls, partitions, and the like. Complete Specification. September 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

11,286. J. W. Ransome. Manufacture of artificial stone and concrete blocks. August 28.

14,853. G. Pankhurst. Improved brick, tile, or slab for building. August 28.

16,234. J. W. H. James. Apparatus for calcining cement materials, hydraulic lime, plaster of Paris, &c. September 18.

16,323. A. V. Bouvier and J. Billoré. Manufacture of bricks, tiles, &c. September 11.

16,110. F. W. S. Stokes. Revolving furnaces for burning, calcining, or roasting cement, lime, ores, &c. September 18.

1889.

11,444. M. J. Adams. Roofing tiles; and formation of iron and other sheets or plates for roofing purposes. August 28.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

13,061. H. Ritter von Dahmen and A. Strauss-Collin. An improved method of extracting aluminium from its oxide, silice, and fluorine bases, such as corundum clay, bauxite, kaolin, eupolite, and the like. August 19.

13,063. H. Ritter von Dahmen and A. Strauss-Collin. An improved method of producing metallic sodium, potassium, and magnesium. August 19.

13,138. H. H. Lake. — From G. W. Cummins and J. H. Coleman, United States. An improved process for treating iron, steel, and other metals to prevent oxidation thereof while in a heated state. Complete Specification. August 20.

13,175. J. Appletree. A substance to join steel with iron and also other different metals together. August 20.

13,277. M. Gledhill. Improvements in the manufacture of cast metal ingots, projectiles, and the like, and in machinery or apparatus therefor. August 22.

13,301. W. Deighton. Improvements in and connected with steel-making and other "water-gas" furnaces. August 23.

13,312. D. Colville, jun. Improvements in or connected with regenerative melting furnaces. August 23.

13,420. G. W. Clark. Improvements in obtaining aluminium. August 26.

13,432. T. K. Rose. Improvements in filtering or separating gold from liquids containing the same in solution. August 26.

13,635. H. H. Jones. Improvements in blast furnaces. August 29.

13,659. W. L. Wise. — From M. Kramer, Germany. Method of hardening steel tubes internally. August 30.

13,717. A. M. Clark. — From La Société en participation Bourbonze et Cie., France. A solder for aluminium and other metals. August 30.

13,718. A. M. Clark. — From La Société en participation Bourbonze et Cie. The production of a new metal or alloy. August 30.

13,787. G. C. Frierer. Preparing iron and steel sheets and other metallic bodies for coating with tin, zinc, and other metals. September 2.

13,830. A. G. Greenway. Improvements in the manufacture of zinc or other metals from hard spelter and other alloys of said metals with iron. September 2.

13,839. H. J. Allison. — From The Great Western Aluminium Smelting and Refining Co. (Incorporated), United States. Method or process for obtaining aluminium. Complete Specification. September 3.

13,986. J. Hansen. Improvements in apparatus to be applied in the smelting of cast-iron borings, turnings, and shavings. Complete Specification. September 4.

14,226. A. J. Boulton. — From M. Castelneau. Improvements in or relating to the treatment of ores and other substances. September 9.

14,235. C. Schreiber and H. Knutsen. An improved process for the treatment of auriferous and argentiferous antimony ores. Complete Specification. September 10.

14,357. E. Dodé. Improvements in refining and separating precious metals. September 11.

14,462. A. J. Campion and J. E. Tenison-Woods. Improvements in processes for cleansing and welding impure scrap iron. September 13.

14,466. I. Butler and T. J. Rickard. Improvements in and connected with machines for coating metal plates with tin, terne, or other metal. September 13.

14,473. M. A. Howell, jun. Improvements in and apparatus for the manufacture of soft back steel. Complete Specification. September 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,343. B. J. B. Mills.—From J. D. Bennett. Obtaining aluminium. September 4.

13,718. C. Meissner. Improved method of working mines. September 18.

14,331. H. Havemann. Manufacture of lead from its ores or compounds. September 11.

15,172. R. J. Atcherley and A. E. Sarti. Copper amalgamating plates. August 28.

15,314. A. Seddon. Apparatus for manipulating ingots and other forms of steel or iron. September 4.

15,572. W. Feld and G. von Knorre. Production of silicium copper. September 11.

15,607. T. K. Cavill. Apparatus for holding and turning ingots and other masses of metal. September 11.

15,708. M. Yglesias. Treating the effluent waters of mines, or other waters holding metals in solution. September 4.

16,061. H. J. Smith. Improvements in steel and iron. September 4.

16,489. Davies Bros. and Co., Lim., and Davies. Preparing iron and steel plates previously to galvanising them. September 11.

16,499. H. B. Fulton. Treatment of quartzose or silicious and sulphuretted ores containing gold, silver, or copper. September 18.

16,569. H. Schneider. A manufacture of steel alloyed with copper. September 18.

17,406. H. H. Lake.—From P. Manhes. Treatment of nickel and cobalt. September 11.

17,410. H. H. Lake.—From P. Manhes. Treatment of nickel and cobalt, and apparatus therefor. September 11.

18,024. H. A. Hunnicke. Extraction of zinc from its ores. August 28.

1889.

3169. F. Ellis. A new or improved metallic alloy. September 4.

8038. H. H. Lake.—From E. Thomson. Welding, soldering, or brazing metals, and apparatus therefor. August 28.

9821. J. Shears. Extracting metals from ores and slags, and the débris of smelting and other works. September 18.

10,288. H. H. Lake.—From O. B. Peck. Apparatus for decomposing chemical compounds and metallic salts, and for desulphurising ores. September 11.

11,406. E. Norton and J. G. Hodgson. Apparatus for manufacture of sheet metal. September 4.

11,686. C. U. Fisher.—From H. F. Lord. Compound for use in welding, tempering, and otherwise treating metals. September 18.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

13,480. W. P. Kookogey. Apparatus for charging storage batteries and other purposes. Complete Specification. August 27.

13,636. F. Hughes.—From E. J. McDonald, East Indies. Improvements in the manufacture of indigo by the application of electricity. August 29.

13,795. P. von Knoblosch. An invention to turn artificial and natural light, even plane atmospheric light, into an electrical current. September 2.

13,818. V. H. Ernst. Improvements in secondary batteries. Complete Specification. (Date applied for 12th February 1889, being date of application in the United States.)

13,864. S. C. C. Currie. Apparatus for automatically charging secondary batteries or accumulators. Complete Specification. September 3.

13,926. E. G. Rivers. The construction of vessels for containing chemical liquids for battery cells and other purposes. September 4.

13,993. G. E. B. Pritchett and H. R. Low. Improvements in electrical safety fuses. September 4.

14,148. J. Kunze. Improved method of manufacturing pipes, tubes, and other articles of metal by galvanic deposits. September 7.

14,155. C. A. McEvoy. Improvements in primary batteries. September 7.

14,162. A. de Méritens. See Class XVII.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,264. F. E. Elmore and A. S. Elmore. Preparing metallic surfaces for the reception of non-adhesive electro deposits. September 4.

15,433. T. J. Handford.—From L. Dnncan. Plates or electrodes for secondary batteries, and method of making same. September 11.

15,626. P. Schoop. Electric batteries. September 4.

16,140. E. Tyer. Charging secondary batteries from primary batteries, and apparatus therefor. August 28.

1889.

12,402. W. P. Kookogey. A galvanic battery solution. September 11.

12,731. W. P. Kookogey. A plate for secondary batteries. September 18.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

13,700. C. Billing. A new or improved manufacture of soap. August 30.

14,364. E. Mansfield. Improved apparatus for and method of extracting oleaginous and other added matters from fibrous spun textiles and other analogous substances. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

9796. J. M. McCallum. An improved soap powder, and method of manufacturing same. September 11.

15,558. H. C. Foulsham. An improved soap powder. September 4.

1889.

900. Flemings Oil and Chemical Co., Ltd., and G. H. Fenner. Moulds for casting rectangular slabs of naphthalene, &c. August 28.

11,660. H. Schuster. Producing hard soap from vegetable or animal fats, or a mixture thereof, and caustic alkaline solutions, without employing carbonates of alkalis or chloride of sodium. September 11.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

13,345. W. P. Thompson.—From P. Leonard and P. Zen, Italy. An improved anti-corrosive composition for protecting iron vessels or the like. August 24.

13,540. K. P. H. Labenow. Improvements in the composition and method of making up bronze colours ready for use. August 27.

13,792. J. J. Carr. An improved material for making whitewash, colour-wash, and water-colour paints. September 2.

14,150. S. Kenyon. Improvements in the treatment of india-rubber for the purpose of dissolving it or rendering it soluble. September 7.

14,479. J. Hanson. An improved furniture polish. September 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,564. T. Baynes, W. H. Doughty, and H. T. Greaves. Paint or composition for coating ships' bottoms, and process of manufacturing same. September 1.

16,035. S. Challoner. Lacquers and varnishes. September 11.

16,185. A. J. Smith. Apparatus for dressing white lead and other colours. September 18.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

13,126. P. Jensen.—From D. Pierson, jun., United States. Improvements in and relating to a new and useful process of chrome tanning leather, and in and to the article produced thereby. Complete Specification. August 20.

13,269. M. J. A. Dargelos. An improved process for tanning skins. August 22.

13,542. R. C. Want.—From G. Mitchell and R. W. Rutherford, New Zealand. Improved means and process for preparing skins and hides for tanning. August 27.

14,535. M. Heslop. Improved process of and apparatus for treating hides, kips, and skins preparatory to the tanning operation. September 14.

XV.—AGRICULTURE AND MANURES.

COMPLETE SPECIFICATION ACCEPTED.

1888.

13,303. R. Nicholls. Apparatus for drying certain farm produce. September 18.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

13,555. R. Raeymaeckers. An improved process and apparatus for the treatment of saccharine and other solutions. August 27.

14,209. G. F. Redfern. From M. Weinrich, United States. Improvements in purifying sugar and other solutions. September 9.

COMPLETE SPECIFICATION ACCEPTED.

1888.

15,815. R. H. Steedman. Treating a product obtained from seaweed. September 11.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

13,054. L. Meyer. Improvements in the method of producing ferments. August 19.

13,231. V. R. Taylor. An improved sparger. August 22.

13,427. E. Craddock. An improved treatment of grain for the production of malt, and apparatus therefor. August 26.

13,454. D. R. J. J. G. Morel. Apparatus for mixing water with malt for supply to mash tuns. Complete Specification. August 26.

13,653. W. P. Thompson.—From P. Marix and N. Notkin. See Class II.

14,162. A. de Méritens. Improvements in treating and rectifying or ageing alcohol or alcoholic liquors or the like by electricity. Complete Specification. September 7.

14,174. A. Savigear and T. J. Scrutton.—From J. Poivet, Nancy. Fermenting liquors. September 9.

14,406. J. Hutchison. Improvements in and relating to the treatment of alcoholic liquors. September 12.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

13,438. C. A. Coombe. Improvements in treating brewers' grains and manufacturing feeding cakes and biscuits therefrom. August 26.

13,439. C. A. Coombe. An improved cattle feeding cake. August 26.

13,652. W. P. Thompson.—From E. Mérian, France. Improvements in the manufacture of oleomargarine. August 29.

13,822. E. Larsen. A method of preparing human and cattle food from cereals or from refuse of manufactured cereals. September 2.

B.—Sanitary Chemistry.

13,279. J. Arnold. Improved apparatus for oxidising sewer gas and deodorising sewage. August 22.

13,280. J. Arnold. Improved apparatus for disinfecting and deodorising sewer gases and noxious matters in soil pipes, drains, and cesspits. August 22.

13,746. W. P. Buchan. Improvements in deodorising or disinfecting rivers and estuaries or other sewage, or other wise polluted collections of water. August 31.

14,128. A. Turley. The manufacture of carbon from town and other refuse, and the purification of sewage and other foul waters. September 7.

14,292. J. Procter. An improved oxidising agent, applicable especially to disinfecting sewage and other waters, and in the mode of preparing the same. September 10.

14,500. T. Jones and J. Jones. Filtering or purifying sewage water or polluted water from works or manufactures. September 14.

C.—Disinfectants.

13,203. J. T. MacMahon. A composition for arresting or preventing decay in wood. August 20.

14,032. J. G. Flower and D. W. Macdonald. An improved disinfecting, deodorising, and preserving compound. Complete Specification. September 4.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1889.

1201. W. Gerbel. Manufacture of milk powder and effervescent beverages. September 4.

B.—Sanitary Chemistry.

1889.

7630. J. Davis. Means for purifying water. September 4.

12,405. H. W. Whiting. Refuse burning furnaces. September 11.

C.—Disinfectants.

1888.

15,676. J. E. Reynolds. Improvements in disinfectants. September 11.

16,463. J. E. P. Meyer. Composition for developing ozonised oxygen. September 18.

18,620. J. Ascough. Antiseptic washing and cleansing compounds. September 18.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

13,246. T. Mitchell. Improvements in or applicable to the manufacture of linoleum and like floor cloths. August 22.

13,425. C. Weygang. Improvements in the manufacture of waterproof boards, paper, and such like material. August 26.

13,657. M. Frisch. Improved press copying paper. August 29.

14,491. T. Volstorff. Improvements in the method of and apparatus for straining paper pulp. Complete Specification. September 14.

14,508. J. A. Causton and J. Challis. Improved process of applying luminous preparation to the surface of paper or other substances. September 14.

COMPLETE SPECIFICATION ACCEPTED.

1888.

16,932. G. Tidcombe. Rolls for pulping fibres for the manufacture of paper, &c. September 18.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

14,327. A. H. Allen. Improvements in the methods of colouring poisonous substances. September 11.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

13,523. W. P. Thompson. — From C. Spiro, United States. Improvements in or relating to mixtures or solutions for developing or fixing the latent images on photographic plates or sheets. August 27.

13,739. W. H. Phillips. Improvements in photographs, and apparatus for effecting the same. August 31.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

13,486. C. O. Lundholm and J. Sayers. Improvements in making and applying explosives. August 26.

13,907. H. H. Leigh. — From La Compagnie Forate, France. Improved apparatus and process for the manufacture of nitro-glycerin. September 3.

14,073. W. Clayton. The production of whistling fire-works. September 6.

14,362. I. G. Gomez and P. Franco. A new or improved manufacture of matches of the vesta type. Complete Specification. September 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

12,871. W. Balch. Shells for signalling at sea, and apparatus for discharging them. September 11.

1889.

11,102. W. H. A. Kitchen and J. G. A. Kitchen. A new explosive called "Cycene," for blasting and other like purposes, and for use in shells for ordnance. August 28.

14,665. W. Schuckher. Manufacture of smokeless gun-powder. August 28.

XXIII.—ANALYTICAL CHEMISTRY.

COMPLETE SPECIFICATION ACCEPTED.

1888.

16,697. N. G. K. Huseberg. Means of determining the percentage of fat in milk. September 18.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 10.—Vol. VIII.]

OCTOBER 31, 1889.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederiek Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

COUNCIL FOR YEAR ENDING JULY, 1890.

President: Sir Lowthian Bell, Bart., F.R.S.

Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Harter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

Editor:

Watson Smith, University College, London, W.C.

ASSISTED BY THE FOLLOWING STAFF OF

Abstractors:

T. L. Bailey, Ph.D.	F. S. Kipping, D.Sc.
G. H. Beckett.	Chas. A. Kolm, Ph.D.
D. Boudix.	F. W. T. Krohn.
E. Bentz.	T. A. Lawson, Ph.D.
Jos. Bernays, M. Inst., C.E.	J. Walter Leather, Ph.D.
E. E. Berry.	A. Liebmann, Ph.D.
E. J. Bevan.	D. A. Louis.
Bertram Blount.	W. Macnab.
Arthur G. Bloxam.	N. H. J. Miller, Ph.D.
C. H. Bothamley.	J. M. H. Munro, D.Sc.
W. Lant Carpenter.	H. S. Pattinson, Ph.D.
E. G. Clayton.	H. T. Pentermann.
Julius B. Cohen, Ph.D.	S. G. Rawson, D.Sc.
C. F. Cross.	A. Rée, Ph.D.
A. R. Davis.	F. W. Renaut.
W. W. Haldane Geo, B.Sc.	Edward Simpson.
C. Napier Hake.	A. J. Smith, B.Sc.
Oswald Hamilton.	Oscar J. Steinhart, Ph.D.
John Heron.	A. L. Stern, B.Sc.
Bertram Hunt.	D. A. Sutherland.
F. Hurter, Ph.D.	Bertram Thomas.
C. C. Hutchinson.	Eustace Thomas.
D. E. Jones, B.Sc.	V. H. Veley, M.A.
W. E. Kay.	R. Lloyd Whiteley.
A. J. King, B.Sc.	A. Wingham.

NOTICES.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. FYRE and SCOTTIS-WOOD, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

LIST OF MEMBERS ELECTED, 23rd OCTOBER, 1889.

Allen, R. L., Roseleigh, Heaton Chapel, near Stockport, assistant analyst.
 Ballantyne, H., 260, Renfrew St., Glasgow, analyt. chemist.
 Bechel, Lezin A., McCall Post Office, Parish of Ascension, Louisiana, U.S.A., sugar engineer and chemist.
 Bond, Louis W., Ensley, Ala., U.S.A., engineer and chemical student.
 Brock, Arthur, Messrs. C. T. Brock & Co., South Norwood, S.E., firework maker.
 Brown, Robt., Beech Mount, Warrington Hill, Northwich, engineer.
 Cochrane, Chas., Green Royde, Pedmore, near Stourbridge, ironmaster.
 Cornish, Vaughan, Ivy Cottage, Newcastle, Staffordshire, science master.
 Craven, Chas. E., Hawthorne Cottage, White Cote Hill, Bramley, near Leeds, chemist and dyer.
 Dawes, J. T., Cefn Mawr, Mold, Flintshire.
 Drummond, Hon. G. A., Montreal, Canada.
 Edwards, Walter N., 4, Herne Hill Road, Loughboro' Junction, S.E., analytical chemist.
 Field, Leopold, Upper Marsh, Lambeth, S.E., candle and soap manufacturer.
 French, Harry B., 1001, Market Street, Philadelphia, Pa., U.S.A., wholesale druggist.
 Friese-Greene, W. E., 92, Piccadilly, W., photographer.
 Fuerst, Jos. F., 4, Copthall Buildings, E.C., drug and chemical merchant.
 Gerrard, A. W., 1, Cantlowes Rd., Camden Sq., N.W., chemist.
 Haines, Reuben, 201, South 5th Street, Philadelphia, Pa., U.S.A., analytical chemist.
 Handy, Jas. O., 95, Fifth Avenue, Pittsburgh, Pa., U.S.A., chemist.
 Hauff, Julius, Feuerbach, Stuttgart, Germany, chemical manufacturer.
 Hennin, Alphonse, Springfield, Ill., U.S.A., metallurgical chemist.
 Hunt, Alf. E., 95—97, Fifth Avenue, Pittsburgh, Pa., U.S.A., metallurgical engineer.
 James, Alf., Cassel Gold Extracting Co., 13, West Scotland Street, Kinning Park, Glasgow, mining engineer.
 Kemp, D. S., 27, Coverdale Road, Shepherd's Bush, W., chemist.
 Kenyon, Thos., Beechwood, Eccles, near Manchester, manufacturing chemist.
 Langenbeck, Karl, 110, West Ninth Street, Cincinnati, Ohio, U.S.A., analytical chemist.
 Lee, J. W., Richmond, Villamanin, Prov. de Leon, Spain, mining engineer.
 Leeds, Dr. Albert R., Stevens Institute of Technology, Hoboken, N.J., U.S.A., professor of chemistry.
 Maconochie, J. R., 1, East India Avenue, E.C., hardware merchant.
 Margetson, J. Chas., Avonside, Melksham, Wilts, india-rubber manufacturer.
 Merck, Dr. C. E., 9, Breite Allee, Darmstadt, Germany, manufacturing chemist.
 Nash, Jno., 122, Mansfield Road, Haverstock Hill, N.W., terra cotta manufacturer.
 Rintoul, Wm., 48, Carnarvon St., Glasgow, analyt. chemist.
 Robinson, Chas. E., Richmond Lodge, Torquay, M. Inst. C.E.
 Sanz, Don Mariano, Fabrica de productos quimicos, Leon, Spain, chemical manufacturer.
 Seymour-Jones, A., Cambrian Leather Works, Wrexham, leather manufacturer.
 Shepard, Dr. Chas. U., 68, Meeting Street, Charleston, S.C., U.S.A.
 Shuttlewood, W. B., 106, Fenchurch St., E.C., export merch.
 Spies, Adolph, 102, Fenchurch St., E.C., chemical merch.
 Spies, Hermann, 102, Fenchurch St., E.C., chemical merch.
 Swinburne, G. W., 245, Broadway, Newport, R.I., U.S.A., civil engineer.
 Wilson, A. E., c/o Ferguson Syndicate Co., Waiorongomai, Te Aroha, New Zealand, assayer.
 Wright, Alf., 8, Bentinck Crescent, Elswick Road, Newcastle-on-Tyne, pharmaceutical chemist.

CHANGES OF ADDRESS.

Babington, P., 1/o Manchester; c/o Percy Hirst, Elmfield, Rotherham, Yorks.
 Barbour, T. F., 1/o Edinburgh; 26, Robertson Street, Glasgow.
 Barnes, Jos., 1/o Avenue Parade; Marl Terrace, Accrington.
 Fuller, C. D., 1/o Braddock; Latrobe, Westmoreland Co., Pa., U.S.A.
 Gillman, G., 1/o Callejon del Caldero; 8, Calle del Angel, Granada, Spain.
 Greenway, T. J., 1/o New South Wales; Port Pirie, South Australia.
 Gregory, Wm., 1/o Lichfield; Walmer Brewery, Kent.
 Hastings, Hugh, 1/o Consterdine Place; 39, Malvern Terrace, Kidderminster.
 Kitamura, Y., 1/o Tokio; bei Herrn Busse, Pawel Strasse III. Brunswick, Germany.
 Lloyd, Jas. D., 1/o Sandwich; 6, Camp Street, Providence, R.I., U.S.A.
 Markham, A. D., 1/o Enfield; St. Nicholas Road, Sutton, Surrey.
 Melville, D., 1/o North Woburn; P.O. Box No. 1, Woodmere, Wayne Co., Mich., U.S.A.
 Sandon, R., 1/o Kentish Town; 21, Archibald Road, Tufnell Park, N.
 Soward, A. W., 1/o Peckham; 144, Friern Road, East Dulwich, S.E.
 Steel, R. Elliot, 1/o Bradford; Hawthorn House, Baildon, near Shipley, Yorks.
 Sumner, R. M., 1/o Liverpool; 53, Stevenson Street, San Francisco, Cal., U.S.A.
 Thompson, G. E., 1/o Smethwick; Morningside Lodge, Kidderminster.
 Timmins, A., 1/o Stanley Villas; Argyll Lodge, Higher Runcorn.
 Wilson, Gordon, jun., 1/o Kirkintilloch; Crestone, Saguache Co., Colorado, U.S.A.

CHANGES OF ADDRESS REQUIRED.

Dempster, A., 1/o Rose Mount, Elland, Yorks.
 Johnson, Geo., 1/o Grange Metal Works, Jarrow-on-Tyne.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.	R. Messel.
H. E. Armstrong.	B. E. R. Newlands.
W. Lant Carpenter.	B. Redwood.
W. Crowder.	T. Royle.
W. J. Dibdin.	John Spiller.
C. Graham.	Wm. Thorp.
S. Hall.	C. R. Alder Wright.
C. C. Hutchinson.	

Hon. Local Sec. and Treasurer:

Thos. Tyrer, Garden Wharf, Battersea, S.W.

SESSION 1889-90.

Nov. 4th.—Mr. C. Napier Hake. "An Account of a Borax Lake in California."

Dec. 2nd:—

Mr. Watson Smith. "Some Notes on Variations in the Products of the Destructive Distillation of different Gas Coals, heated separately in the same retort and under similar conditions."

Mr. J. Hauff. "Cresotinic Acid and its Applications." 1890.

Jan. 6th.—Mr. C. T. Kingzett. "Peroxide Hydrogen. Its Preservation and Commercial Uses."

Feb. 3rd.—Messrs. A. H. Allen and W. W. Staveley. "On the Properties and Applications of Metallic Compounds of the Phenols."

Notices will be found in the Journal and other Scientific Papers.

Liverpool Section.

Chairman: F. Hurter.

Vice-Chairman: A. Norman Tate.

Committee:

J. Campbell Brown,
H. Brunner,
E. Carey,
H. Denoon,
T. Fletcher,
H. Gaskell, jun.

F. Gossage,
S. Hamburger,
W. D. Hornum,
D. McKechnie,
G. Shack-Sommer,
Henry Tate.

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

Dr. C. A. Kohn, University College, Liverpool.

Nov. 6th.—Dr. F. Hurter. Presidential Address on "The Condensation of Hydrochloric Acid."

Dec. 14th.—H. T. Carr. "The Dinsmore Process for the Manufacture of Coal Gas."

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Nottingham Section.

Chairman: Sir John Turney.

Vice-Chairman: L. Archbutt.

Committee:

Jno. R. Ashwell,
F. Clowes,
J. B. Coleman,
W. A. Curry,
H. Forth,
E. Francis.

J. M. C. Paton,
S. J. Pentecost,
C. Spinkman,
H. J. Staples,
J. T. Wood.

Treasurer: S. V. Holgate.

Hon. Local Secretary:

R. L. Whiteley, University College, Nottingham.

First Meeting, Wednesday, November 6th.

1. Address by the Chairman.

2. Mr. L. Archbutt. "Laboratory Notes."

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Communications.

THE PRESENT POSITION AND PROSPECTS OF THE CAUCASIAN PETROLEUM INDUSTRY.

BY PROFESSOR D. MENDELÉEFF.

THE following communication has been addressed from St. Petersburg to Ludwig Mond, Esq., as past President of the Society of Chemical Industry, by Professor Mendeléeff:—

"Having observed that the Berlin correspondent of the 'Standard' of July 25, 1889, as well as the 'Morning Post' of August 7, have spread abroad in England a rumour to the effect that the natural supply of crude oil in Baku is coming to an end, and that consequently a lapse in the production of Russian naphtha was to be expected, I conceive that it will be of great importance that the correct state of affairs should be known as regards the present and future of the naphtha industry of the Caucasus. To this end it will be necessary in the first place to mention that even four years ago, and in Baku itself, these rumours as to exhaustion of supply were freely set up and circulated.

"These rumours then strangely resolved themselves into a variety of proposals to the Government with regard to means, which might in or one other way be adopted to prevent the expected misfortune. Messrs. Nobel and Ragosin proposed then that a tax should be imposed on the crude oil, and a demand was made for powers to expend an enormous sum in experimental and exploratory borings in the outskirts of Baku for the purpose apparently of finding some source which might compensate for that now supposed to be fast approaching exhaustion. In order to obtain light as to the actual state of the naphtha industry at Baku, the Government, which is deeply concerned

in its successful development, firstly, ordered that the practical geological investigations in that region should be vigorously pushed on; and, secondly, sent me in the summer of 1886 to collect authentic intelligence.

"One of the results attained in 1887 by the exploration under the Department of Mines (Engineer Torokin, the reports of Professor Meller, &c.) was that there had never been the least reason to suspect the exhaustion of the naphtha springs in Baku. In a special report (1866) to the Minister of Domains, Michael Nikolajewitch Ostrowsky (The Baku Naphtha Industry in 1866), I stated that the rumours in question were due partly to entire ignorance as to the symptoms of exhaustion of the naphtha (these symptoms have been well studied in Pennsylvania), and also doubtless partly to the intrigues of certain parties, who supposed it to be to their interest to propagate such statements. "The study made in 1886 of the Baku industry, familiar to me since 1863, has proved:—

(1.) That not one single trustworthy symptom of exhaustion of the Baku naphtha region has presented itself.

(2.) That not having the means to store large supplies of naphtha which suddenly appear, a large quantity of the oil is lost (flowing into the lakes and sea). This is specially the case when oil springs burst forth, and leave no time for preparations for collection and storage. The cessation of the profitable yield of some of the wells has been proved to be owing to the obstruction of access to the same by the naphtha, for the new borings made close beside them very often yielded naphtha in abundance. But the upper layers, especially near Balakhani, which have been worked for a long period, proved to be almost exhausted. At the same time, however, in the direction of the village of Romany, exploration was commenced at a later period, and now promises to yield enormous quantities of crude oil, the layers here being situated deeper (not, of course, because the exploitation was begun later). The region of Beybat (where the wells of Messrs. Tagieff, Djajely, and others are to be found) yields naphtha in abundance, and is situated close to the town of Baku. It is, so to say, cut off from the Balakhani-Sabondeli naphtha region, and suggests the belief that besides the principal naphtha fields of the Baku regions, there are many other outlying and isolated naphtha regions like the region of Beybat. The precipitate conclusion as to exhaustion has more frequently been based upon the results of the wells lying near the village.

"Balakhani figures are put down *ad libitum*, quite forgetful of the existence of the Beybat region. In order, however, to show how unfounded is the judgment as to the exhaustion even of the region of Balakhani, I give here the figures taken from the reports of Messrs. Benkendorf and Mauramtzef (Group XVII.) on the Balakhani region. These I verified in 1886, and I may say that the entries are made more correctly than on the other spots. There were in 1866 in all five wells, and these remain until now (1886). At the beginning the wells were worked slowly, and very often became obstructed.

The yield was in:—

	*Poods.		*Poods.
1876.....	727,000	1881.....	2,286,000
1877.....	1,250,000	1882.....	1,404,000
1878.....	1,200,000	1883.....	2,455,000
1879.....	1,066,000	1884.....	6,498,000
1880.....	1,150,000	1885.....	6,250,000

"The very pumping of the naphtha from the existing wells is not regularly conducted, but increases during the summer months, when the demands are greater, and at times ceases altogether during the winter. The third result of my study in 1886 was (3), that the wells which yield daily less than 200 poods of naphtha are not worked at all, or at all events only when prices rise. (4.) That the highest possibility of the annual supply from the Baku region is far from being attained yet, judging of the small number (about 170) of wells now at work, and taking into consideration the large space of land covered, undoubtedly containing naphtha, but not used for exploitation by the owners (as Mirsoieff and Kokoreff) for want of the required capital, and the lands belonging to the Government, which are also left unexploited owing to the requests of the

* 1 Pood = 36·03 lb. avoirdupois.

owners of the wells, who are afraid of new competitors. (5.) That the highest degree of productiveness as regards crude oil in the Baku region is only attainable when the pipe line to the Black Sea is constructed. (6.) That, even admitting the possibility, in the far future, of the exhaustion of the Baku oil-bearing region, still other regions of the Trans-Caucasus will be available, and by means of the then existing pipe line will be able to afford ample supply both to the Black Sea and the Caspian Sea. (7.) That in consequence of the relative geological recency of the formation of naphtha in the Caucasus, and of the continuation of the activity of the mud volcanoes, it would be quite unsafe to say that even at the present time those underground processes do not continue the result of which is a replenishment of the oil, this being very likely forced up by internal pressure through layers of superficial sands. (8.) That the principal expedient for counteracting exhaustion must be considered to be the increase of the utility of the naphtha; in other words, it ought to be worked up into more valuable products, as benzene, heavy oils, vasclin, and tar, in addition to the products only now obtained, viz., kerosine and lubricating oil; for the residues (astatki), which are used now as fuel, can with great profit to the country be substituted by coal, since the exploitation of the abundant seams of that mineral to be found on the Donetz, Ural, and in the environs of the Moscow district, &c., would be an easy matter. Owing to the above-stated reasons I am decidedly inclined to consider the construction of the Caucasian pipe line an absolute necessity for the prosperity of the naphtha industry in the Caucasus. This view has been hitherto strongly held by the Minister, M. N. Ostrowsky, who still continues to hold it, notwithstanding the strong opposition of the Baku people, because of their supposed personal interests—supposed interests which would nevertheless directly oppose themselves to the general interest of Russia, and more or less to that of the world at large. For further details I must refer you to my book, which I have the honour to transmit, together with this letter.

"The clearest proofs of the correctness of the opinion that in Baku there are no signs of exhaustion, are to be found in two circumstances: (1.) At the end of the year 1886, and in the following year, when comparatively very few new borings had been made, such large flows of naphtha took place, that, until that time, their like was never before observed, never either in America or in Baku; and (2.) during the years following, the productiveness in the same region, just as before, increased from 116,000,000 poods (about 1,900,000 tons or about 12,000,000 barrels), as in 1885, to 180,000,000 poods, as in last year, 1888.* However, when exhaustion occurs, as in the Pennsylvania region, the productiveness of the said region falls off very quickly, and the naphtha fountains disappear there, and are replaced by water or only gas fountains. According to information received recently from Baku (during 1889), from the 1st January to the 1st August, about 125,000,000 of poods of crude oil have been already extracted, and several powerful fountains have been spouting up their contents this very year.

"Particularly productive was the flow of Mr. Kotscheieff's spring, and the greater part of its crude oil ran into the lake of Romanino, as is almost always the case under similar circumstances in Baku. Consequently, without any doubt, there are no signs of exhaustion of the crude oil in the Baku region up to the present time.† I will not attempt

any examination of the different forms of ignorance or duplicity which prompt the framing of such calculations or commercial speculations as those referred to. They are based on the foibles of human nature, and are of but ephemeral stability.

"I will try now to offer some definition of the connexion between the geological or physiographical position of the springs, and the supply of material, in accordance with the personal acquaintance I have formed with the subject. As the Alleghany Mountains—in the geological sense—have served to indicate the Pennsylvania issues of naphtha, just in the same way the mountains of the Caucasus—between the Black and Caspian Seas—served to indicate in that district the naphtha there. Respecting the reason of connexion between the mountains and the issue of naphtha, I will not speak here, because I desire to remain on practical ground without entering upon that of hypothesis.‡ But the connexion of the mountains with the naphtha-beds is clear from the fact that the districts facing or fronting the mountains are the regions where naphtha is obtained. They lie, indeed, parallel to the direction of the mountain range. The Devonian and Silurian sand strata of Pennsylvania are similar in this respect to the naphtha sands in the new tertiary strata of the Caucasus. The former are, however, geologically old—the latter are recent. Here is the fundamental distinction between the American and Caucasian naphtha deposits. With them are probably united two other fundamental distinctions. *Firstly*, the naphtha in Pennsylvania has been found only on the western side of the Alleghanies, but the Caucasus is full of naphtha from the north, south, and on both sides, at the Black and Caspian Seas. This must be explained in the following manner:—The old beds had many natural opportunities of getting opened, of letting out their naphtha supply, of getting washed away and becoming lost for the use of the people, but the younger naphtha deposits of the Caucasus had less chances of this. *Secondly*, near the Alleghanies and near the naphtha wells of Pennsylvania there are no mud volcanoes, which are to be found very often in Baku, in Tamany, and generally near the Caucasus, and form, so to say, the natural satellites of naphtha. They are evidently the breathing holes of the terrestrial interior, which evolve mud, water, and steam, and let out the burning gas. In Pennsylvania, long ago this process terminated, which thus still continues in the Caucasus. We find naphtha here and there in similar conditions with regard to space, but the conditions of geological periods in both countries are very different. Comparing Pennsylvania with the Caucasus we must constantly bear in mind these differences. Ignoring them, we fail to explain peculiarities which become very clear after comparing Pennsylvania with the Caucasus. As regards the Caucasus, so long ago as in biblical times, and, indeed, long time before the Russians came there—the inhabitants of the place used the naphtha which came then to the surface as illuminating oil.§ To give the names of these naphtha-bearing districts surrounding the Caucasus on all sides, would serve no other object than filling several lines with names. But the question arises, why does working only take place in Baku? Why is naphtha not obtained in Tamany, Gury, on the Terek, Chemakhy, and such other localities of the Caucasus, in such large quantities as near

* In Russia, all the reports with regard to naphtha represent the weight, and not the volume. 1 pood = 16·38 kilos., or a metrical ton is about 61 poods (or puds). In America, all the reports of naphtha are given in the measure of capacity, viz., in casks and barrels. A normal barrel contains 42 gallons, but accounts are more often given of barrels of 42 gallons. One cask contains 4·54 kilos. of water, consequently, at the specific gravity of about 0·8 as for the light varieties of American naphtha, each barrel (42 gallons) will average about 152 kilos., or contain about 94 poods, of naphtha. For such comparatively heavy kinds of naphtha as are usual in Baku, and having the specific gravity of about 0·86, 42 gallons must be reckoned as about 164 kilos., or about 10 poods of naphtha.

† The upper layers in the smallest part of the now-worked region show a diminution in abundance of crude oil (they yield less than before per day), and from these layers the gas has already escaped; but the deeper layers are as yet full of crude oil saturated with gas, and in the very depths of the same, that is to the very lowest layers, there was no need to go, because up to the present the depth of the ordinary wells at Baku does not exceed 700–900 ft., whilst in America the depth of the same often exceeds 1,500–2,000 ft. As regards some dry holes which never did yield any crude oil, and

some wells which diminished their yield, as well as the diminution in abundance of crude oil in the upper layers whilst the local productiveness gradually increases, these clearly cannot be taken as signs of exhaustion, they are but normal conditions of ebb and flow, which are determined by the natural conditions of the layers of naphtha. By the naphtha exhaustion of a given place must be understood the cessation of so far profitable yields from all the wells conjointly (taking the old as well as the new wells) of the given locality. One well may yield more naphtha than hundreds of unsuccessfully chosen borings, and if the general quantity of supply increases, especially when at the same time the chances of a successful boring are favourable, and if there are besides naphtha-bearing regions, as yet untouched, which undoubtedly will yield rich supplies (such regions are near the village of Romanyn, in the environs of Baku), then there is no foundation whatever for talk about exhaustion.

‡ My hypothesis of the origin of naphtha explains this connexion. It is explained in my work: "The Naphtha Industry in Pennsylvania and in the Caucasus, 1877." Also, in the "Revue Scientifique," 1878, and "Jahrbuch d. K. K. Geol. Reichsanstalt (Wien)" Bd. 29, 1885.

§ The people then held the Baku naphtha sources leasehold from the Persian Government, for commerce with the naphtha as an illuminating oil was highly developed near the Caspian Sea.

Baku? There are two essential reasons for this. The first is, that the Volga, even since ancient times, has formed the principal water-way to Baku, and along this same water-way the Russo-Asiatic commerce is still carried on. Near Baku there is a rock which bears the name of the robber Stenka Rasin, who is reputed to have gone there with his evil-minded comrades for the sake of plunder.

To Russians this road is well known. From Baku to Vischny, to Perm, and to the very heart of Russia, all the naphtha products go by water, and at such cheap rates that it is less costly to get over all this distance of many thousand versts (1 verst = 0.66 mile), than to transport the naphtha, even from Chemakhy, over a hundred versts by land. This is the principal reason of the prominence of Baku, which is also situated on the sea coast, and has developed its naphtha industry since the year 1860. The initiative in this direction was taken by Mr. W. A. Kokoreff, who wishes to supply Russia with illuminating oils. There was also another reason. Many borings have been made at Kuban (A. N. Novoseltzeff, Mr. Twedel, the French Society), and also near the Tzarskie Kolodtzy (Simence), but there, as in Pennsylvania and Virginia, the naphtha is not found in such abundance; there are very seldom springs to be found. The naphtha must be drawn or pumped, in order to collect it. Consequently the naphtha costs there almost the same price as in Pennsylvania, from 10 to 12 copecks per pood on the spot; but in Baku, the very first wells, especially in the years between 1870—80, yielded such an abundance of naphtha that wells which yielded less than 200 poods per day were not worked at all, for working expenses would not be covered. This is owing to the price of the crude oil on the spot in Baku, which very often, when there are no springs, is 2 copecks, and sometimes 3 copecks, per pood, or even more; but if springs burst forth, the naphtha of which goes to the lakes situated amidst the wells, then the price goes down very often to $\frac{1}{2}$ copeck per pood, provided that only a part of the 100,000 poods of crude oils yielded daily by the Baku springs can be gathered.*

* The price of the crude oil in Baku, much more than in America, where there are store reservoirs, changes very much in accordance with the demand, because this material is scarcely stored up at all, and the naphtha is sent direct to the refineries according to the periods of sale. Then, but especially in the summer, during the navigation on the Volga, the work at the wells is increased, as well as the distillation in the refineries. Thus the increase of prices of the crude oil, of which the English newspapers are now talking so much, and which corresponds with that of the prices of the crude oil in America, where the average price in 1877 was 67 cents per barrel, and was never lower in any year whatever. In 1888 the average price was 88 cents; and again, in June 1889, 84 cents, and in July 1889, from 90 to 102 cents on the spot, according to the quotations of the Pittsburg Exchange. This is by no means a sign of exhaustion, but merely that during this summer the demand for kerosine has increased. Owing to this, new borings have been commenced, and it may be anticipated, as it very often was in Baku and in Pennsylvania, that next year the supply will surpass all demands, and prices will go down. For my own part, I must remark that when the price for crude oil becomes 11 copecks per pood, there cannot be expected any development of the supply; there will be a stoppage, and not an increase of the business, although the owners of refineries have their profits in it.

The price of 5 copecks per pood, according to my opinion, is a desirable and a normal one, and one calculated to develop supply. Such a price being 3 or 4 times lower than American—(5 copecks per pood = 50 copecks per cask, or about 25 cents per barrel, according to the present exchange, but in Pennsylvania a cask or barrel costs on the spot now not less than 50 cents)—cannot act sensibly on the price of the naphtha products, which, owing to a simple speculation fluctuate a great deal more than from the fall or increase of the price of the crude oil in the above-mentioned proportions, viz., from 3 to 5 copecks per pood. Here I will make the remark that since the year 1857 the price of crude oil in the United States has risen from 67 to 95 cents per barrel, or per cask about 6 copecks, but the price at Baku for the same period did not rise more than 3 copecks per pood. If there were a possibility of competition of the Baku naphtha with the American, then the same possibility now remains. With the termination of the pipe line this possibility would be still more evident. Until now there has been no possibility of the export of large quantities of products, but then there would be; now there is no possibility of extracting large quantities of illuminating oils not presenting any danger with respect to risks from fire, but then there would be. Now the Americans with their numerous pipe lines fix the prices of the naphtha products all over the world, but then this can and will also be done by the Baku people; now there are no large profits left in Baku, but then would arise the possibility of making new borings in all the Trans-Caucasus, out of the profits derived from the naphtha.

I may state here that the price of the Baku naphtha products mostly depends on the use which is made of the naphtha, that is, to work up into products, also the residues (astatky or astatki), which remain after the kerosine has been got from the naphtha.

(1 copeck = $\frac{1}{100}$ th rouble, and the par value of a rouble = 38 $\frac{1}{2}$ pence English.—Ed.)

Such natural abundance of naphtha as occurs in the Baku region has not been discovered up to the present in any other parts of the Caucasus which have been as yet tested by borings, nor in Pennsylvania, nor in Canada, nor in any other part of the world. Very likely there is some connexion between this fact and that of the mud volcanoes, which are up to the present active, like those of Kyr-Maku, which are situated close to the naphtha region of Balakhani in the environs of Baku.

“There is a Russian adage: ‘From good no one will expect anything else but good to spring.’”

“This adage is well applied here. From the existing good in Baku there has been no need up to the present to look out for any other good thing. There are plenty of places on the Caucasus where naphtha may be sought for, and amongst them possibly might be discovered regions not worse than those of Baku, springs, equally powerful and recent, and certainly more durable than those of Pennsylvania, but there exists no motive, because in the very environs of Baku there is plenty of land, without any doubt, containing naphtha which has not yet been touched, owing to the following reasons:—The Government having sold, in the years following 1870 (according to the Rules of the 17th February 1872) one part of the naphtha-bearing lands, afterwards stopped the sale and the lease of such lands. Kokoreff and Mirsoieff were the principal buyers from the Government of large districts containing naphtha; each of them bought lands for 1,000,000 of roubles. They began and continue to work only on very insignificant parts of their large territory (because they have spent so much for the acquisition of land that they have little left for working capital), and now wait until the lands and naphtha rise in price and value. The Government does not allow the local peasants to sell or to lease their lands for the purpose of getting naphtha. Consequently the district worked years ago in the environs of Baku is the same district now.† And one’s astonishment is excited that on so small a spot, altogether about 5 square kilometres, people continue until now to make new borings, continually pump the naphtha, and still continually get springs bursting forth. It is not at all strange, that formerly the depth of the wells was only a few sagues (1 sague = 7 feet), later on the workers had to go deeper to 40—80, and afterwards to 100—120 sagues. We do not observe anything like this in Pennsylvania.‡ In the geologically young Baku, people have remained all the time on the same spot, on the same 5 square kilometres, and have continued to pump only such wells as yield every day on the average not less than several hundreds of barrels. In Pennsylvania the number of working wells during the time of the highest period of supply, which was in 1882, attained 19,000 wells, and 30,000,000 barrels of naphtha have been got in a single year.§ consequently

† Whilst in the United States from the year 1860 and upwards (on account of the rapid exhaustion of each region) people were obliged continually to go over to new regions in search of supply of naphtha, and tens of thousands of borings were made (from 1876 to 1886 no less than 31,707) on a surface of hundreds of square kilometres, whilst all this time operations were confined rigidly to the already mentioned 5 square kilometres in Baku.

‡ In those geological periods, amounting to thousands of years, during which were formed the naphtha beds of Pennsylvania and the Caucasus, the naphtha seems to have risen to the surface, become oxidised and evaporated, and was thus lost for exploitation. If the naphtha had not got out by itself from the underlying beds, people would never have known of its existence. During these long geological periods a small stream of the outflowing naphtha could empty a very rich layer a great deal better than hundreds of bored wells. Owing to this, every naphtha-field in the Caucasus is more to be relied upon with regard to the quantity of naphtha to be obtained than similar fields in Pennsylvania. For this reason also, ideas as to the approaching exhaustion of the working region in the Caucasus based upon signs manifesting themselves in America, cannot be entertained. Besides, there is nothing to prove, as yet, that the formation of naphtha in the Caucasus is completed. The mud volcanoes here give vent still in very strong eruptions.

§ The daily receipt of crude oil in the United States from that time diminished very greatly.

	Barrels
In 1882 the daily yield was	82,393

(Continued on p. 756.)

every well yielded per day only $4\frac{1}{2}$ barrels on an average, or taking (light naphtha) a barrel of 9 poods—about 40 poods. Now at Baku there are at work about 200 wells (the exact number is very difficult to state, there do not exist as yet proper statistics, but there are such wells, and only pumped when the demand for crude oil increases), and during seven months there have been received about 125,000,000 poods,* and consequently per day on an average every well yields about 2,800 poods or a barrel of 42 gallons, containing about 10 poods (we include the heavy naphtha), the average daily receipt of naphtha in Baku is, at the present time, 280 barrels from each well. In February 1886, of which period I have full reports, there were in operation about 170 wells, and the daily average yield was 446,000 poods or, per well on the average, about 2,600 poods per day, consequently an increase and not a decrease in the supply is visible. Let us take for comparison the figures of the last Stowell's Petroleum Reporter, Pittsburgh, Pa., United States of America (August 1889). During the seven months (up to August 1st, 1889) the average daily yield of naphtha from all the wells in the United States of America was about 56,000 barrels, or about 510,000 poods, whilst in Baku it was about 580,000 poods per day. These figures are very close one to another, although eight years ago the supply in Baku was six times less than in America. During the seven months of 1889, in the United States of North America, 2,800 new borings were made, and during last year (1888) 1,515 borings, whilst in Baku all the time from the beginning of the years of 1860 until the present time, the number of borings are much below any of these figures. Let us suppose that now there are working in the United States only those wells which have been made during the last four years,† the average number of them will be about 11,200 wells, against 200 wells in Baku, consequently the average daily supply of each well in the United States is 45 poods or 5 barrels, whilst in Baku it is 2,800 poods or about 280 barrels. The daily average of the yield of the new borings in America (June and July 1889), does not surpass 16 barrels or 150 poods of naphtha. Such wells not one of the Baku naphtha-owners would be willing to work, because at the price of 3 cop. per pood, the 150 poods of naphtha would give an income of about 4 rs. 50 cop., but the maintenance of the steam-power, ropes, and workmen, amount, per day, to about 6 or 7 rs. Even at the price of 5 cop., 150 poods would not cover the working expenses and the cost of the boring, at the existing prices of the same in Baku. Consequently there is nothing astonishing that on the spot where naphtha is received in the United States of America, the price for naphtha is much higher than in Baku. In America about 90 cents per barrel or about 18 cop. per pood is the figure, while in Baku from 2 to 5 cop. per pood or about 10 to 25 cents per barrel.

"If in Baku there should be anything like the state of the North American wells with regard to their quantity or their

But in Baku at the same time the supply greatly increased, giving the quantities in barrels (1 barrel = 10 poods), the general average was:—

	Barrels.
In 1882 the daily yield was	13,838
1883 " "	16,541
1884 " "	24,653
1885 " "	31,851
1886 " "	32,889
1887 " "	41,500
1888 " "	50,312

here we must call attention to the fact, that out of 37 million barrels, which were in stock in the United States of North America in 1884, now there are only 14½ millions. But in Russia the stock increases from year to year, because people have begun to construct reservoirs. When the pipe line is constructed, this stock will no doubt still further increase.

* It is known that figures separately taken (and not conjointly) of the statistics very often are not sufficiently exact. But if we take that the supply during the seven months of this year in Baku was really 125,000,000 poods, then it will be easily understood why the prices for crude oil went up, because the refineries demanded more than in former years. Besides at the present time the price for the crude oil in America went up, and Baku must be already considered as a rival of America. All the rumours of the exhaustion in Baku began when the pieces of crude oil went up. This is a matter of commercial transactions, but the exhaustion is a matter of nature; here does not exist a direct connexion.

† In former times Stowell's Reporter gave the number of working or active wells (for instance, in 1885, as 23,586 wells), but now it does not exhibit these figures, which are very difficult to prove.

supply, or with regard to the extension and changes of regions or even with regard to the prices of naphtha, then it would be possible to speak about the exhaustion of the Baku region. But even then there would be left the lands belonging to the Government, to the peasantry, to Kokoreff and Mirsoieff, which are until now untouched, and are quite near to Baku, without reckoning the neighbouring lands, and the whole of the north and the south of the Caucasus, where the making of borings is not prohibited, but where it would be insanity to begin borings when in Baku: (1) The pumping is going on when there is a demand; (2) When not all the land has been investigated; (3) Before there really are observed any signs of exhaustion; and (4) When there are no great pipe lines, which could at a low price convey the naphtha to the Black and Caspian Seas.

"But why is the working of the lands not allowed for those who desire to operate them? Why is the pipe line not constructed? All this, combined with the rumours of exhaustion, form very complicated questions, principally owing to the manner in which the local people act. About this, however, I may say something on another occasion. Suffice it to say, I do not know of a single sign of the incipient exhaustion of naphtha in the Baku region. But suppose I admit the fullest exhaustion of the naphtha in Baku, let us see what may follow next in the Caucasus, supposing at the same time that the pipe line there from Baku to Batoum is finished.‡

"Along the pipe line there are plenty of naphtha springs, not only from Baku to the south and west, but also in the interior of the country, near Tzarskie-Kolozetz, near Tiflis, near Kutais, in Gouria, &c.

"These places, when the pipe line exists, will be united by pipes with the Caspian Sea, as well as with the Black Sea, and will consequently be, with regard to commerce, exactly in the same position in which the North American naphtha regions are.

"At Philadelphia, New York, Buffalo, &c., &c., the refineries will be at the sea shore, but the naphtha wells will be on the continent at a distance of 100 versts. And if even in one of the districts of the Trans-Caucasus there will be found naphtha in abundance, this will be at a low price conveyed to the sea, but at all events, on the sea-shore it will not be dearer than the American naphtha, for the Caucasian naphtha is young, whilst the American is old. Nowhere, not even when borings are made by hand, and the naphtha is got out by baling, does the naphtha cost in the Caucasus the 18 cop. per pood which are paid on the places of supply in the United States of America. Owing to the present means of boring, and the knowledge people have acquired of this business in the Caucasus, and thanks to the Baku supply, one can be sure that the average price of naphtha on the spot in the whole Caucasian district will be always one-half or one-third cheaper than at present American prices. The pipes of the Caspian Black Sea pipe line will offer then a conveyance to this naphtha which does not exist now, because in the Trans-Caucasus there is only one road—the railway—the only line which is bound to convey all the risky products of this country.

"And notwithstanding that there is against the pipe line a powerful intrigue, the latter cannot succeed in changing the real state of the business. The nearer the period of exhaustion approaches, the more powerful becomes the cause of the pipe line.

"For the present, besides the local use of the Caspian region, there are only two ways for exterior sale: the Volga, which is frozen during the winter, and the Trans-Caucasian railway. By the Volga the naphtha products go to Russia, and only a small part of them abroad (by a very dear, and tedious system of conveyance (Nobel's), by the Volga, and then by rail to Liban, &c.).

‡ Without the pipe line, then of course the naphtha business in the Caucasus will be at an end, Russia itself will get the naphtha products from America. Where the construction of pipe lines is unhindered, Europe and Asia will pay America for the naphtha, that which the Standard Oil Company will demand, and the use of the cheapest naphtha illuminating oil will considerably diminish, because with the Virginia and Ohio naphtha much cannot be done. From this it is plain who will have the best of the exhaustion at Baku, if there is no pipe line.

"In this way about 25 millions of poods of refined oil are conveyed.* And about the same quantity can be sent by the Trans-Caucasian railway to the South of Russia and abroad. This is all that can be sent from Baku at more or less profitable prices out of the 180—200 millions of poods of the naphtha gained. It is clear that a great quantity of naphtha is left and this is a kind of cheap merchandise (astatki), which is used as fuel, instead of coal, of which there are immense supplies in the Don and Ural. Meanwhile out of this astatki can be got, as experience has proved (and this has been demonstrated in the Physico-Chemical Society), together with kerosine, a safe illuminating oil (point of inflammation higher than 40 °C.), which I named Baku oil. At present it cannot be produced, although 50 to 60 per cent. of it can be got out of the Baku naphtha (besides benzene, lubricating oils, vaselin, and tar), and consequently could be obtained from it now at Baku to the extent of 100 millions of poods. But at present there are only means for the transport of 50 millions of poods of illuminating oils. But when the Baku crude oil can be conveyed by the pipe line to the Black Sea then there will be great profit in producing similar safe oils, which will increase the use of naphtha illuminating oils.

"Consequently all rumours of exhaustion of the Baku naphtha regions must not stop the English and Russian people who have commenced operations with Caucasian naphtha. The naphtha will suffice for the whole world, for all purposes.

"If there should arise new and still more artful and insidious arguments in order to delay foreign transactions with the Russian naphtha products, as I have some reason to believe will arise, then please have the kindness to inform me, that I may render such further explanation as may be necessary. The substance of the matter is, that Russia itself uses so little of the illuminating naphtha oils (about 20 millions of poods annually), and the abundance of the Caucasian naphtha is so great, and the expense of getting the naphtha so slight, that the exterior commerce with the naphtha producers is on the one hand an important help for Russian industrial interests, and on the other gives to the world the cheapest naphtha products, and thus leads to mutual benefit.

"To everything that will be purposely stated against this affirmation I am ready to reply, for the sake of the interests of my country and of the universal development of peaceful commercial relationships, and transactions. I consider it of great importance that our country is able to supply the world with an illuminating oil, safe as regards risks from fire, which is more than can be said of the American kerosine, which it is bound to replace ultimately."

August 27 (September 8), 1889.

THE MANUFACTURE OF PRUSSIAN OF POTASH (FERROCYANIDE OF POTASSIUM).

A paper read before the British Association, Newcastle-on-Tyne, 1889,

BY J. B. READMAN, D.S.C., F.R.S.E., F.C.S., EDINBURGH.

As far as I am aware very few thorough investigations have been conducted during late years with the view of arriving at a more economical method of producing this important commercial salt.

There is perhaps no chemical operation carried on on the large industrial scale which is so wasteful and so scientifically imperfect. The wear and tear of apparatus, the loss of nitrogen, the excessive consumption of coal, and the loss of potassium by volatilisation, lixiviation, and recovery, are each and all so abnormal under the present process of

manufacture, that it is matter for surprise the process has so long survived in an age characterised by rapid strides of progress in almost every other branch of chemical industry. During the last decade or more a very great deal of attention has been paid to the recovery of ammonia from blast-furnace gases and coke ovens, and to increasing the yield of ammonia during the destructive distillation of coal and of shale, but little or nothing has been done in the direction of saving or utilising the ammonia or the nitrogen evolved in the manufacture of ferrocyanide of potassium.

It has been stated that out of every 100 parts of nitrogen existing in the animal matters employed in this manufacture, only 45 to 50 parts are utilised, and that the remaining 50 to 55 parts are lost, passing off, not as ammonia to any great extent, but principally as free nitrogen.

Yellow prussiate of potash is, commercially at least, the starting point of the manufacture of the cyanides and ferrocyanides, and although much of its importance, especially as a means of preparing blue pigments, has gone, it is still a substance of considerable manufacture.

Before giving a short review of the history of prussiate, and of the methods that have been proposed or practised to improve the process of manufacture, it may be well, in the first place, briefly to describe the process at present in use in this country.

Present Mode of Manufacture.—It consists in introducing dry nitrogenous animal matter, such as horns, hoofs, woollen rags, leather, &c., into molten carbonate of potash contained in a small, but very thick and heavy (15 cwt.) cast-iron pot, heated externally by a strong fire. The pot is provided with an iron agitator, which is kept constantly in motion during the operation. The nitrogenous material is introduced into the pot slowly, and in small quantities at a time. The carbon and nitrogen combine together, forming cyanogen, which in turn combines with the potassium, forming, some authorities say, cyanide, others, ferrocyanide of potassium.

The mouths of the pots are practically open to the air, and at each addition of nitrogenous material a flame shoots forth carrying with it a large proportion of the nitrogen. It is at this stage of the process that the chief waste of nitrogen takes place.

The iron required for the formation of the salt is derived wholly from the cast iron of the pots and agitators, and this wear, aggravated by the presence of sulphur in the organic matter, and by the high temperature at which it is necessary to conduct the operation, renders the working life of the prussiate pots a very short one.

The fused mass after the nitrogenous matter has all been introduced (called "metal") is ladled out of the pots. It is then allowed to cool, and is lixivated much in the same way as black-ash is treated in the Leblanc soda process. The "metal" contains cyanogen equivalent to about 16 per cent. to 20 per cent. of ferrocyanide of potassium, which may exist, as before remarked, as cyanide, but on lixiviation becomes ferrocyanide by double decomposition—

and about 60 per cent. of carbonate of potash in excess called "return alkali," the remainder, 20 per cent. to 24 per cent. being insoluble matter, chiefly carbon.

The clear liquor from the lixiviating vats is boiled down, and a first crop of crystals of yellow prussiate is thereby obtained. These crude crystals are then recrystallised at least once to fit them for the market. The mother-liquors obtained from the first crystallisation are evaporated down and put through the process again. Afterwards, when they become very foul from accumulation of sulphides and other salts, they are evaporated to dryness and put through the black-balling furnace for recovery as carbonate of potash.

The insoluble residue from the lixiviation of "metal," consisting largely of carbon derived from the animal matters, was formerly a waste product; but it has recently become of value as a substitute for animal charcoal in the decolorising of paraffin wax.

Historical.—It appears that Prussian blue was first produced in this country in 1724, by Woodward, who obtained it by deflagrating a mixture of nitre and argols, and calcining the product with dry blood. Further

* Of course in this way a great deal more could be conveyed; astatki as well.

investigations were made by Scheele, some years later; also by Berthollet in 1787; Porret in 1814; and by Gay Lussac in 1815, who discovered cyanogen.

Attention was paid to the manufacture of prussiate by Muspratt in 1820, and by Kuhlmann in 1838, who was the first chemist to propose the making of cyanogen by passing ammonia over red-hot carbon and condensing the cyanogen so formed in alkaline solution.

Lewis Thompson, of Newcastle-on-Tyne, about 50 years ago, was the first to draw attention to the production of cyanogen when coke, iron, and potash were ignited in free access of air.

Bramwell and Hughes about this time (1844) started the process in Newcastle of producing cyanides by passing air over a dried mixture of carbon saturated with potash and heated to a high temperature.

Bunsen and Playfair detected cyanogen in the gases of the Alfraton iron furnaces a little above the tuyères, and Bunsen proposed the erection of a potash blast furnace, with air blast, for the production of cyanide of potassium. At the meeting of the British Association held in Cambridge in 1845, a "Report on the Gases evolved from Iron Furnaces," by Professor Bunsen and Dr. Lyon Playfair, was read. The following extracts are taken from the Report:—

"It will be observed that the gases from the inferior parts of the furnace contain cyanogen." * * * * *

"This gas appears immediately over the point of entrance of the blast, and again disappears at a small elevation above it, so that at the top of the bushes only small traces of it are observed."

It appears from the report that a hole was bored over the front of the furnace, 2 ft. 9 in. above the level of the tuyère, and as soon as the perforation was complete a gas issued from it, possessing strong illuminating powers, and burning with a yellow flame, from which came abundant vapours of white smoke. An iron pipe was introduced into this hole, and the gases which poured out of the tube, under a pressure of several feet of water, were so richly laden with cyanide of potassium that precautions had to be taken in approaching it that the experimenters should not suffer injury from this poisonous material.

Some Woulff's bottles were arranged and connected to the pipe, in the first bottle which was originally empty, a rich white sublimate of dry cyanide of potassium was deposited, while water contained in the second bottle became a tolerably strong solution of the same salt.

The potash, on further investigation, was found to come from the calcined iron ore and from the coal employed. The experiments proved (1) that the nitrogen of the cyanide was not derived from the nitrogen contained in the coal, as the temperature at that part of the furnace must have previously deprived the coal of all its nitrogen; and (2) that cyanide of potassium is volatile at high temperature.

More recent suggestions.—Patents for improvements in the manufacture of cyanides or ferrocyanides have been taken out in this country during the last 20 years. Some of the claims are for the employment of baryta as the base, and air as the source of nitrogen;* others are for the extraction of cyanides from the spent oxide or waste lime of gas works; others are for improved apparatus for producing cyanides where air is employed as the source of nitrogen. Besides these, many minor modifications not only of the apparatus employed but of the materials have been proposed. For example, the employment of reverberatory furnaces have been proposed in place of the cast-iron pots. A preliminary carbonisation of the organic matters has also been suggested, but as far as I am aware none of these proposals appear to have been adopted in this country. The process I have described still seems to stand firm as the only one here practised.

Experiments by the Author.—With the object of ascertaining to what extent cyanides can be produced by passing dry ammonia gas over carbon saturated with potash and other substances while heated to redness, I made the following preliminary laboratory experiments, using potash, soda, lime, and baryta as the bases. The results of these experiments I have tabulated, to show at a glance the yield of cyanide from a given material. I may say that the respective salts were added† to the wood charcoal and iron filings, and the mixture was thoroughly dried before being strongly heated to form cyanogen compounds with the gaseous ammonia. The furnace employed in these experiments was at first an ordinary laboratory combustion furnace heated by a row of Bunsen's burners, and the tube into which the saturated dry wood charcoal was placed was made of malleable iron $\frac{1}{2}$ in. internal diameter.

* Since this paper was written, Mr. Mond's interesting experiments in this direction have been made public in his presidential address to the annual meeting of Society of Chemical Industry in London, 1889. (This Journal 1889, 505–510.)

† These salts that were soluble were added in concentrated solution, and these that were not were mixed with the charcoal along with water and dried.

The experiments were further continued in a malleable iron pipe 4 ft. long by 2 in. in diameter, heated in a furnace with coal fuel. The ammonia gas derived from dry chloride of ammonium and slaked lime, was generated in an apparatus heated to the temperature required to expel all the ammonia, and was connected by a tube to the pipe containing the saturated charcoal. It is evident from the experiments—(1.) That whatever affinity barium may have for cyanogen at very high temperatures it has no power to attach itself to the latter at temperatures at which cyanide of potassium can be readily produced. (2.) If a large excess of potash be present in proportion to the nitrogen the whole of that element contained in the ammonia is resolved into cyanides. (3.) That the same amount of cyanogen is formed whether iron filings are added to the saturated wood charcoal in the first place or not. (See Experiments Nos. VII. and XIV.)

In addition to the experiments that are tabulated, trials were made with air passed over the saturated charcoal under similar conditions to the other experiments, but the result showed that no cyanides were produced.

As stated previously, these experiments are only preliminary ones. It is my intention to follow them up on a larger scale, and at the same time using higher temperatures.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

New or Improved Means and Apparatus for Producing Cold. E. Bazin, Paris, France. Eng. Pat. 10,361, July 17, 1888. 8d.

In this invention the pressure at which water is ordinarily supplied to houses in town is utilised for compressing air, which, in expanding, produces cold for cooling, freezing, and preserving purposes. Two methods are shown. Water from the main pipe enters a vertical receiver under pressure, and compresses the air in the upper part, and forces it through a cooling coil extending the whole length of the chamber. The lower end of this coil is connected by a tap with a second coil contained in a horizontal cylinder, through which the air also passes and enters a refrigerating box, in the "jacket space" of which it expands and produces intense cold. The water escapes from the receiver by a pipe at the bottom, and its height is regulated by a gauge. Or the water enters the upper part of the receiver through a series of holes, in the form of rain. The enclosed

air is thus cooled and compressed, and is still further cooled by being brought in contact with ice in a receiver, and from which it passes into the refrigerating chamber. There are six claims and two sheets of drawings.—E. S.

Improvements in Multiple Evaporating Apparatus. T. Slater, London. Eng. Pat. 10,493, July 20, 1888. 11d.

This invention consists in evaporating and concentrating fluids by passing them over open trays heated by steam, the trays and steam-supplying passages being fixed in a cylindrical chamber, in which a vacuum is maintained by means of an air-pump.

For details the drawings attached to the specification must be consulted.—E. S.

Improvements in Condensing Apparatus. E. Theisen, Cologne-on-the-Rhine, Germany. Eng. Pat. 11,268, August 3, 1888. 11d.

This invention is intended to provide a simple and efficient condenser for steam and other vapour. To effect this, the condensing chamber is constructed with a very extensive surface in a small space, by arranging a number of annular vessels concentrically one within the other, their entire surface being kept constantly wet by means of jets "preferably of warm water." A fan acting upon this surface causes very rapid evaporation, which withdraws the heat from the condensing chamber and causes the rapid condensation of the enclosed vapour. To prevent the steam or other vapour from passing too quickly through the condenser, a tortuous course is given to it by providing the vessels internally with inclined or spiral divisions. Several modifications of the apparatus are shown in the five sheets of drawings. There are four claims.—E. S.

Improvements in Cold Air Refrigerating Machines. W. Garden, Dalston. Eng. Pat. 12,327, August 27, 1888. 11d.

In this invention, intense cold for refrigerating purposes is produced by the compression of air, which is afterwards cooled and expanded. The compression and expansion cylinders are mounted on opposite ends of the bed-plate, the pistons of both being worked from a common crank. The cooling-chamber is placed beneath the bed-plate, and is provided with a number of perforated screens, over which the water from the circulating pump is caused to run, as the air is forced through them. The compressed air then passes to the expansion cylinder, which is surrounded by a jacket, around which the dense air circulates before passing into the cylinder by a hollow slide-valve, which works on rollers, and is kept close to the cylinder by adjustable levers. "In this way, the cylinder being surrounded by a body of dense air at a uniform temperature, irregular contraction of the walls of the same, and consequent undue friction on the piston is avoided." Ports in the valve correspond with others at each end of the cylinder, and allow the air to pass alternately to either side of the piston to be expanded, the same ports in the cylinder acting as discharge passages when the hollow slide-valve uncovers them.

There are four claims, and the specification is accompanied by four drawings.—E. S.

An Appliance or Device for Introducing or Injecting Gases into Liquids contained in Casks or other Vessels. The Brin's Oxygen Company, Limited, Westminster, and P. B. W. Goble, Dartford. Eng. Pat. 13,723, September 22, 1888. 8d.

The object of this invention is to prevent loss in introducing gases into liquids contained in casks or other vessels. A tubular main has an elastic seating at its lower end, over which is a chamber which carries a plug, and a spring to press it forward. Above this chamber the main is screwed, and provided with a nut having handles for rotating it, and so raising a collar with lateral eyes for the attachment of

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	3d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	1d.
" 2s. 4d., " " 3s. 4d.	2d.

a chain, which passing round the cask keeps the whole apparatus securely in position. The upper part of the tubular main is connected with the gas inlet pipe. A hollow rod (except at the upper end) passes through the tubular main, and on pressing the knob at the upper end it drives the bung before it and enters the cask, at the same time that an opening corresponding with that of the gas inlet allows the gas to flow in. The cask being filled the rod is drawn upwards, when the plug mentioned before is driven forward into position, and a blow on the top of the rod forces it into the bung-hole and closes the cask, when the apparatus can be removed. There are four claims and one sheet of drawings.—E. S.

Improved Means for Fixing the Glass Tubes of Syphons.
E. R. Vaughan, Belfast. Eng. Pat. 15,200, October 23, 1888. 6d.

THE improvement consists in the means of fixing the glass tubes of syphon-vessels containing aerated waters and other beverages, and which can be easily detached, instead of being rigidly "fast" as heretofore. A cap-piece of any suitable non-metallic material has an internal screw. A short tube or collar of india-rubber is fitted over the glass syphon tube which is slightly enlarged at the upper end to retain the collar in position. The cap-piece is then screwed over the collar and forms a flexible but hermetically sealed joint. The advantages of this improvement are: (1.) Preventing the enclosed liquid from coming in contact with the under-surface of the cap; and (2.) In retaining its utility should the glass tube be broken. There are two claims.—E. S.

Improvements in Machines for Grinding White Lead, Paint, Printing Ink, and other similar Substances or Compounds. H. Clark, London. Eng. Pat. 16,034, November 6, 1888. 8d.

THE machine consists of five rollers of granite or other suitable material having bearings capable of adjustment in slots in the frame which carries them, so that the distance between any consecutive pair of rollers can be varied at will. Power is communicated by a shaft with fast and loose pulleys to the rollers by toothed wheels and pinions, of such sizes that each roller is driven at a speed about one-third greater than that of the previous one, and thus the surfaces of each pair of rollers have motion relative to each other. The substance to be ground is fed on to the first roller and is received from the last by a shoot provided with a scraper. The bearings of the rollers are not rigidly fixed in the slots mentioned above, but are cushioned by spiral springs, which allow them to yield in the event of any hard lump of material being accidentally introduced into the machine.

—B. B.

Improvements in Apparatus for the Discharge of Gases Stored under Pressure. G. Vincent, London. Eng. Pat. 130, January 3, 1889. 6d.

THE improvement relates to apparatus for simplifying the conversion and discharge of nitrous oxide (N_2O) from a liquid to a gaseous condition for the purposes of inhalation; also for similarly converting and discharging oxygen gas for use in oxyhydrogen lanterns, and for other gases.

Two iron bottles containing the gas in a liquid form are securely fixed in a horizontal position to a flat board or tray). In front of each bottle are two upright brass supports, carrying a spindle, which ends in a loose socket, into which the nozzle of the bottle fits. On the top of the spindle is placed "a roughened foot bracket pedal-piece," which when moved in a "to and fro" direction revolves the spindle, and carrying with it the socket which is fitted into the nozzle, gives the operator control over the escape of the gas. There is one claim and one drawing.—E. S.

Improvements in Means or Apparatus for Use in Filtering.
J. E. Warren, Cumberland Mills, U.S.A. Eng. Pat. 9204, June 4, 1889. 8d.

THE improvement consists in providing a filter in which the sedimentary matter held in suspension by the fluid may be effectually removed from it and the filter. A circular tank is divided by suitable walls into a central chamber, and an annular space round it is divided into chambers by vertical walls, and constitutes the outlet chamber of the filter. The central chamber contains the filtering material, which rests on a perforated plate. A pipe, forming a well, extends through the filter bed to its upper surface, and is provided with outlet and inlet pipes, both of which are controlled by valves. The fluid to be filtered is acted upon by a revolving agitator, consisting of an arm having fingers with blades attached to them, and is rotated by a shaft, which has also a vertical motion which is regulated by automatic mechanism. The heavier impure particles gravitate towards the centre and are precipitated at the bottom of the well, while the lighter particles gravitate towards the walls of the chamber, where they are collected in a peripheral gutter connected by pipes with the well. There are five claims, and the specification is accompanied by two sheets of drawings.—E. S.

Improved Method of and Apparatus for Distilling Sea Water and other Liquids. G. W. Hovgaard, Copenhagen, Denmark. Eng. Pat. 9815, June 14, 1889. 6d.

THIS invention refers to a mode of distilling water or other liquids. Reference is made to Normandy's double-distilling condenser, in which the boiler steam is condensed in a vessel surrounded by the sea water (this Journal, 1887, 813). In this improvement the boiler steam is first caused to perform work in compressing the secondary steam, and the latent heat of the secondary steam instead of being thrown away in the water of circulation is used for evaporating the water. A steam compressor, which is a reciprocating double-acting pump, is driven by any suitable means, and after drawing steam from the evaporator and compressing it, drives it into an annular condenser. The exhaust steam from the cylinder is led to a central condenser, both condensers being cylindrical and multitubular in construction, and the annular condenser is placed outside the central one. A perforated screen placed immediately above the level of the evaporating sea water checks ebullition and prevents salt water being carried over in the annular condenser by priming. The steam which is forced into this condenser is at a higher temperature than the water surrounding it; heat will therefore pass through the shell of the condenser to the boiling water in the evaporator, and the steam will condense and give off its latent heat to the water in the evaporator. In this way fresh water is formed in the annular condenser. The patentee claims greater economy, no deposition of scale, and no priming as the advantages of his improvements. There are two claims and one sheet of drawings.—E. S.

Improvements in Filters. T. Gentzen and A. Wegener, Berlin, Germany. Eng. Pat. 10,251, June 24, 1889. 6d.

IN this filter a combination of sand, coal, and asbestos is used. A cylindrical vessel has a large flange at either end for the attachment of the top and bottom raised covers, an india-rubber diaphragm being placed between the cylinder and the covers. To the lower diaphragm two metal rings are attached, the upper one forming a case in which small pieces of coal are placed, and kept in position by a fine wire sieve, and underneath and lying above the diaphragm is a layer of asbestos. The whole of the cylinder is filled up with fine sand up to the upper diaphragm. In the middle of the cylinder is a cock and pipe for letting off the impurities, a fine wire gauze at the inner end of the cock preventing the sand from passing out. The water to be filtered enters through the upper cover and flows out at the bottom. The filter has a flange at each end by which it may be attached to any convenient place. There are two claims and one drawing.—E. S.

Improvements in Hydrometers and in Apparatus in Connection therewith. J. V. Davis, Treloue, Bohemia. Eng. Pat. 10,123, June 27, 1889. 6d.

This invention is intended to render hydrometers and similar instruments more suitable for large establishments, where the observer is exposed to heat, noxious gases, and the steam and vapour of the liquids to be tested. A lever having the fulcrum at one end carries at the other end a metallic float, which is enclosed in the vessel carrying the fluid to be tested, which is kept in constant circulation and at the same level. As the float rises or falls it moves a pointer on a dial, which can be observed at a distance, or being connected with suitable apparatus supplies a continuous and self-registering record. There are four claims and one drawing.—E. S.

II.—FUEL, GAS, AND LIGHT.

Gaseous Fuel. Sir Lowthian Bell. A paper read at the Paris Meeting of the Iron and Steel Institute, 1889.

For obvious reasons, when power is once generated, the sooner it is applied to the duty it has to perform the better. In like manner, that form of motion known as heat, does its work most economically when the same rule is observed. Of course, it often happens that a sacrifice has to be made in order to meet the circumstances of particular cases. A steam-engine of moderate size is often seen storing up its energy in a hydraulic accumulator, in order to transmit it when wanted to a purpose far beyond the power of the prime motor directly applied. Again, for the Siemens furnace 15 to 30 per cent. of the heat of the coal is devoted to convert it into the gaseous form, in order that the latter, and the air required for its combustion, may be made to serve as vehicles for returning heat to the work to be performed. This is done because, without this stimulus, the temperature obtained by burning coal in the ordinary way would not suffice for the object in view. In the hydraulic accumulator and in the Siemens furnace there is a considerable sacrifice, but it is one which, for the reasons given, is quite justifiable.

I have been led to make these introductory remarks in consequence of having been requested by the Council of the Iron and Steel Institute to prepare a paper on a gaseous fuel known as water-gas. The compound nature of water was discovered by Cavendish and Lavoisier towards the end of the last century, and already in 1801 Fourcroy mentions the fact of hydrogen being separated from it by contact with heated charcoal. Eighty-five years afterwards the product of this reaction has been brought largely under public notice, and it is because the natural laws to which I have briefly alluded, have been, to some extent, lost sight of in the recommendations advanced in favour of water-gas, that I have complied with the wishes of my colleagues.

The gaseous fuel used in the Siemens furnace is known under the name of "producer-gas," and the manner of its manufacture is too well understood to require any description on the present occasion. It varies in composition somewhat according to the kind of coal employed. For my purpose, it will be assumed, in making it, that we have to deal with a specimen of coal consisting of 70 of fixed carbon, 16 of coal-gas, accompanied by 14 of ash, oxygen, and nitrogen.

The producer-gas so obtained will consist by weight of 16 parts of coal-gas, 163·3 carbonic oxide, and 222 of nitrogen. Using the centigrade unit in the calculation, 7,200 calories will be taken as the heat equivalent of the coal employed for the gas I am about to examine, and it will be assumed that the latter is received at the regenerators of the Siemens furnace after being cooled.

We have then to consider—		Calories.
100 of coal × 7,200 calories, equal to		720,000
By the combustion of the producer-gas there is as follows:—		
16 of coal-gas × 10,000 calories		160,000
163·3 of carbonic oxide × 2,400 calories .		391,920
		<hr/> 551,920
Difference		<hr/> 168,080

which difference is loss, and represents 23·3 per cent. of the whole.

In a recent publication dealing with the question we are considering, it is stated that "gas as an economical fuel has come among us, and that it has come to stay." In support of this opinion we are reminded of the immense service which the natural gas, in the United States, has rendered to industry.

Gaseous fuel, however, is not the stranger, at all events to the members of this Institute, which might be inferred from this language. I mention this, after calculating that something like 4,000 million cubic feet of gases are daily consumed at the blast furnaces of Great Britain. As regards the American gas, which I saw in use so long ago as 1876, at Pittsburg, any comparison between it and a factitious gas is, in my judgment, entirely illusory. In Pennsylvania a mere hole is bored in the ground; this taps the subterranean store, which rushes to the surface under a pressure of 200 to 300 lb. on the square inch, and the gas is then impelled along a pipe by its own elasticity to the very furnaces at which it is to be consumed. To obtain producer- and water-gas, a much larger and infinitely more expensive hole or holes have to be dug and fitted with costly and powerful machinery. Besides the coal, worked at great cost, vast volumes of air and great weights of water have to be set in motion. The coal has then to be transported, often for many miles, along a railway, and converted into gas, which, instead of being an almost perfectly pure combustible substance like that found in America, is mixed with an enormous volume of inert hydrogen.

It will be convenient here to describe in brief terms the process recommended for making water-gas. A capacious cylinder of iron is lined with fire-brick, and provided with the necessary apparatus for introducing the fuel, resembling in principle the cup and cone of our blast furnaces. The fuel employed is recommended to be in the form of coke, into which, after being lighted, a current of air is forced, until the whole mass is brought to a high temperature. The blast is then stopped, the orifice for charging is closed, and a jet of steam is passed through the now highly-incandescent carbon. The steam is decomposed, its oxygen burns the carbon into carbonic oxide, setting free the hydrogen, and this mixture constitutes the so-called water-gas, which is stored in gas-holders such as those used in ordinary gas-works. It consists of one volume of hydrogen and one volume of carbonic oxide, the weights being in the proportion of 1 to 14. A gas of this composition, where a very intense temperature is required, is for certain purposes very valuable, because of all substances with which we are acquainted, hydrogen gives out, when burnt, the largest quantity of heat. As an example, while a unit of carbon, in forming carbon dioxide, affords 8,000 calories, one unit of hydrogen generates 34,200 calories, in the formation of water.

Now, if by burning one unit of carbon we could generate one unit of hydrogen, the exchange effected in the water-gas apparatus might be a very profitable one. Such a condition of things would, however, be directly opposed to the known facts of the case.

Chemically, the change in producing this water-gas is expressed by $\text{H}_2\text{O} + \text{C} = \text{H}_2 + \text{CO}$. Now, the heat required to tear away hydrogen from its associated oxygen in water is not less than that which is evolved when these two gases unite; hence, $2 \times 34,200 = 68,400$ calories. The weight of the combining equivalent of the carbon required to effect the change is 12 times that of the two units of hydrogen, and the heat generated by this quantity of carbon being burnt to carbonic oxide is $12 \times 2,400 = 28,800$. Thus something more than 14½ units of weight of carbon will be required to generate one unit by weight of hydrogen.

Now, as only six units of carbon are being burnt in the cylinder for this quantity (one unit) of hydrogen, it will easily be understood that the incandescent carbon, which has served to generate the water-gas, is very speedily cooled below the temperature required for the decomposition just described. When this point is arrived at the steam is shut off, and air is turned on again, in order to obtain a store of heat ready for a further production of water-gas. Thus, it will be seen, the operation consists in alternately making producer-gas, which, when using coke, is a mixture of carbonic oxide and

nitrogen, and water-gas, with which we are now more immediately concerned. In calculating the amount of heat required to supplement that generated before commencing to make the water-gas, all we need to know is the quantity of carbon burnt to the condition of producer-gas, and that which enters into the composition of water-gas. According to the work I have already quoted, 25 per cent. only of the actual carbon used enters into the latter, the other 75 per cent. being converted into producer-gas, containing 68 per cent. of inert nitrogen. From 25 parts by weight of carbon there will be generated of water-gas 62.50 parts, containing 4.16 of hydrogen and 58.34 of carbonic oxide. The producer-gas from the remainder (75 parts) of the carbon will weigh 551.19 parts, of which 376.19 will be incombustible nitrogen and 175 carbonic oxide. The following estimate contains the full quantity of heat these two gases are capable of generating by their combustion:—

Water-gas:—	Calories.
4.16 of hydrogen from steam	$\times 29,400 = 122,304$
58.34 of carbonic oxide	$\times 2,400 = 140,016$
	<hr/> 262,320
Producer-gas:—	
175.00 of carbonic oxide	$\times 2,400 = 420,000$
276.19 nitrogen	
551.19	<hr/> Calories..... 682,620

Had the 100 parts of carbon been burnt direct, the heat generated would have been 800,000 calories.

Hence the loss is 14.68 per cent. Inasmuch, however, as coke was used, and the 100 parts may be taken to represent 150 of coal, we have this quantity to multiply by 7,200 calories, rather a low product for coal, which gives 1,023,780 calories, thus bringing up the deficit to 37 per cent.

In employing coke as a material in the gas generator, there is not only the loss of combustible matter which is incurred at the coke-oven, but the labour, &c. in conducting the process of coking. It is obvious, therefore, that if coal can be employed, it is in that form that the fuel should be used—i.e., if ever a large demand for water gas was to arise. I have been fortunate enough to receive an account from a Moravian work containing the particulars of making 6,041,155 cubic metres of water-gas, in obtaining which 29,734,731 cubic metres of producer-gas was generated, in order to heat the contents of the apparatus in the manner described. It would thus appear that each metre of water-gas is accompanied by 4.92 metres of producer-gas. The analysis of the coal is not given; on this account, and for the purpose of more exact comparison with what has already been said, I will assume its composition to be that of the specimen already mentioned, viz., 16 of coal-gas, 70 of fixed carbon, and 14 of ash, oxygen, &c.

In the metre of water-gas, consisting of equal volumes of hydrogen and carbonic oxide, we have:—

Litres.	Grms.
500 hydrogen	= 44.8
500 carbonic oxide	= 625.0 = carbon 267.8

The producer-gas consists of—

Litres.	Grms.
370 coal gas distilled in heating the carbon	= 206.83
1,440 carbonic oxide distilled in heating the carbon	= 1,805.19 = carbon 773.6
8,110 nitrogen oxide distilled in heating the carbon	= 3,921.23
4,920	<hr/> 5,933.25

Solid carbon..... 1,041.4.

In this, the nitrogen is about 63.2 per cent. of the total volume, and 61 per cent. of the weight. The carbon in the coal-gas amounts to 109.52 grms., which is considered to remain unchanged in the producer-gas. The carbon thus burnt for the producer-gas is 2.88 to 1 for that in the water-gas, instead of 3 to 1, as allowed in the description when coke was employed.

From these figures it follows that we are concerned with 1,041.4 grms. of carbon as carbonic oxide in the two gases, added to 109.52 grms., contained in the 370 litres, or 206.83 grms. of coal-gas.

The heat capable of being produced by these two substances is—

$$\text{Carbon, } 1,041.4 \times 8,000 = 8,331,200 + 206.88 \text{ coal gas} \times 10,000 = 2,068,800 = 10,400,000.$$

When converted into water- and producer-gases, we have to deal with the following quantities of heat by their combustion:—

Water gas containing—	Grms.	Calories.
Hydrogen from steam	44.8 $\times 29,400$	= 1,317,120*
Carbonic oxide	625.0 $\times 2,400$	= 1,500,000
		<hr/> 2,817,120
Producer-gas containing—		
Coal gas	206.83 $\times 10,000$	= 2,068,800
Carbonic oxide	1,805.19 $\times 2,400$	= 4,332,456
Nitrogen	3,921.23	—
		<hr/> 6,401,256
		<hr/> 9,218,376

These two sets of numbers show therefore a loss of 11.36 per cent. in gasifying the coal.

It is, perhaps, worth comparing the assertion made in general terms in the pamphlet of the relative proportion of carbon received in the form of water-gas and as producer-gas—

In the equation $\text{H}_2\text{O} + \text{C}$, we have $\text{H}_2 + \text{CO}$ for water-gas.

In the equation $\text{O}_2 + \text{C}$, we have 3 CO for producer-gas.

The weight in the two equations of H is 2, and that of carbon 48, or 1 of H to 24 of carbon. Of oxidised carbon, in the example just examined when using raw coal, there was in the gases 44.8 of hydrogen and 1,041.51 or 23.24 of carbon for 1 of hydrogen. Now the heat of 24 parts, by weight, of carbon burnt to carbonic oxide means 57,600 calories, which have been expended to obtain 1 part of hydrogen, which, when burnt to steam, is worth 29,400 calories—the loss being therefore nearly 50 per cent. of the heat generated in order to obtain the single unit of hydrogen.

Hitherto I have only spoken of the loss of heat involved by gasifying the fuel before using it, and as the coal is cheaper than coke, we may confine ourselves to that as the material to be used. It is, however, not coal but gas that we have finally to deal with, and we must consider the cost of conversion. According to the return I have received from Germany, each ton of coal treated cost, in its gasification, no less than 12s. 2½d., made up by the following items:—

	£	s.	s. d.
Labour	1,686	14	2 11½
Steam	1,286	12	3 6½
Fire-bricks and clay	79	14	0 2½
Stores	113	16	0 3½
Repairs	369	8	1 0
Sundries	34	10	0 1
Interest and redemption	1,560	0	4 1½
	<hr/> 4,480	<hr/> 14	<hr/> 12 2½

It is not our usual practice in this Institute to consider purely commercial questions, but the substitution of coke or coal by gaseous fuel is one which seems to involve some reference to the question of cost.

In the pamphlet to which I have more than once referred, the expense of converting coke into the two gases is such that it works out per ton of the coke used:—

s. d.
1 0.84 for labour.
1 5.17 interest and depreciation.
0 2.17 sundries.
<hr/> 2 8.18

The labour and other expenses at the Moravian work appears to me very high, and with this observation I must leave the question of cost to be decided by members themselves.

It is stated that solid fuel, under ordinary circumstances, only gives a useful effect of 20 and 25 per cent. of the total

* Hydrogen burnt to water gives 34,200 calories, and to steam only 29,400 calories.

heat units capable of being afforded by coal, whereas as high as 90 per cent. can be had from gas, qualified, however, by the statement that it must have a high percentage of combustible gas and a great calorific intensity. This, of course, must mean the water-gas alone, for the producer-gas contains, as we have seen, 63 per cent. of inert nitrogen and very little pure hydrogen, but it must be remembered that this less important combustible gas represents something like 68 per cent. of the heating power of the two gases, against 32 contained in the water-gas.

I am, however, at a loss to understand whence this inference is drawn as to the inefficiency of solid fuel. The raising of steam and smelting the ores of iron may certainly be included within the category of "ordinary circumstances," and yet it is no uncommon thing for fuel to evaporate 60 per cent. of its theoretical quantity of water, and, as regards our blast furnaces, having regard to the chemical conditions to be observed, 90 per cent. of the full power of the fuel is accounted for by the duty performed.

To account for a supposed inferiority of solid fuel, it is assumed by the author, from whom I am quoting, that it is imperfectly oxidised. I have to do with a large number of boilers fired with coal, and at the Clarence Works we frequently consume 120 million cubic feet of blast-furnace gas per day. I am prepared to assert that oxidation, in my experience, is as complete with the one kind of fuel as with the other. The quantity of heat evolved by each is, of course, easily ascertained, and the only disturbing cause in any comparison between the two is the quantity and temperature of the gases resulting from combustion. In this particular no doubt the net loss is in favour of water-gas, because the exchange of carbonic oxide for hydrogen necessarily reduces the weight of the chimney-gases passing away.

I propose now briefly to summarise the results in the following manner:—

1st. A specimen of coal containing 70 per cent. of fixed carbon, 16 per cent. of coal-gas, and 14 per cent. of ash, nitrogen, &c., will be examined in a calorific point of view, and its power stated when simply burnt in an ordinary furnace.

2nd. Producer-gas as supplied to the open-hearth steel furnace obtained from the same coal, and its heating power also ascertained.

3rd. The same coal converted into water-gas and producer-gas by the processes described, and the united power of these two products calculated as before, on the supposition that for 1 of carbon in the water-gas 3 of carbon is found in producer-gas.

1. Coal as burnt in an ordinary furnace:—	Calories.
100 parts, yielding 7,200 calories per unit =	720,000
Chimney-gases, estimated after making the necessary allowance for oxygen in the coals, 1,129 units	
× 427° C. × 24 Sp. heat =	115,700
Loss in this case by chimney-gases is equal to 16·07 per cent.	

2. Producer-gas from the same coal as that used in Siemens furnaces, without the addition of steam:—

	Calories.
70 of carbon will give 133·33 of carbonic oxide × 2,400 =	391,992
16·00 of coal-gas × 10,000 =	160,000
Sensible heat transmitted to furnace.....	62,411
	<u>614,403</u>

Heat in chimney-gases, 1,129 × 377° C. × 24 S. heat = 102,151
Loss at chimney equal to 16·61 per cent.

In the former statement respecting producer-gas, no note was taken of the sensible heat, because it was wished to compare the heat evolution with the water-gas process, where the gases are cooled.

3. Water-gas and its accompanying producer-gas:—

Water-gas—	Calories.
17·5 of carbon = carbonic oxide, 40·83 × 2,400 =	97,992
Hydrogen from steam, 2·928 × 29,400.....	86,024
	<u>184,016</u>
Producer-gas—	
22·5 of carbon = carbonic oxide, 122·5 × 2,400..	294,000
Coal-gas, 16 × 10,000	<u>160,000</u>
	454,000
Sum of heating power of water-gas and producer-gas.	<u>638,016</u>

Heat in chimney-gases assumed to be of the same temperature as that when burning ordinary producer-gas.

779·7 × 377° × 24 S. heat = 70,547 calories = 11·05 per cent.

These figures intimate that each 100 units of the three kinds of fuel burnt there is afforded by—

Coal.....	83·93
Ordinary producer-gas.....	71·14
Water-gas and its producer-gas	78·80

Of course, it will be readily understood that these results are not given as effective; but the loss, at the same description of work, say for raising steam, being considered identical, the relative value of each is assumed to be as above stated.

In cases, however, where an intense temperature is required in order to do the work in hand quickly, water-gas may be highly advantageous. Some years ago I had an opportunity of seeing such an application at Essen in the welding of corrugated boiler tubes, and the work was admirably done.

A very important application of water-gas is mentioned, viz., for illuminating purposes. For this object the gas, itself destitute of any value in this direction, is made to heat filaments or stems of magnesia. These become so brightly incandescent as to vie, it is alleged, with the electric light, and in consequence, the water-gas is largely used in the United States, instead of coal-gas.

I have nothing to guide me in forming any trustworthy idea of the relative quantity of water-gas required in comparison with ordinary gas for a given amount of light. In the pamphlet already named, 9,000,000 tons of coal is given as the yearly consumption among gasworks in this country; and upon one occasion it was mentioned that a volume of coal-gas, which would require a 36-inch pipe for its transmission, might, in the event of water-gas being employed, be conveyed in one of 14-inch. If this be true, it means that water-gas, supposing the friction to be the same in each case, which is far from being the fact, is at least 810 times as powerful as coal-gas, which is probably a mistake.

A good deal of stress is laid on the application of water-gas to the manufacture of open-hearth steel. I doubt whether, in an operation where a more moderate heat suffices, it can be worth while to seek to obtain one of a more intense character. At one steel-work with which I am concerned, the ingots were formerly heated in Siemens furnaces. These were abandoned, and ordinary coal-fed fires used in their place, and the saving of fuel effected by the change has been very marked. I should, therefore, be somewhat surprised if, with longer experience, there will be found any material advantage in using the water-gas in open-hearth steel furnaces.

It would appear from the figures used for representing the relative values of ordinary producer-gas, compared with water-gas and its accompanying producer-gas, that the sum of the latter gives a better result than the former, viz. 78·80, as against 71·14. The difficulty, however, will be, when the richer gas is wanted, to find a market or use for the poorer, which, it must be remembered, represents 71 per cent. of the heating power of the whole. Looking at the question broadly, it seems clear that nothing can be gained in a calorific point of view by the proposed gasification of our fuel, and that to the loss in this respect has to be added a very sensible amount by the cost of this operation. This observation has reference to the general application of heat, and to that only. The limit, therefore, to the use of gaseous fuel will be the opportunities in which a more expensive form of intensely hot fuel like water-gas is wanted, and where to this extent there will probably be opportunities enough of utilising the producer-gas. For general use, however, I think solid coal is not likely to be superseded by any form of factitious gaseous fuel.

POSTSCRIPT.

Since referring to certain information concerning the manufacture of water-gas in Moravia, I have received from my friend, Mr. Paul Kupelwieser, the director of the establishment at Witkowitz, permission to use his name as my authority for certain statements contained in this communication.

I find I was in error in supposing that coal had been used in the generators, the fuel employed being small coke valued at 10s. per ton, whereas in a letter to our secretary it is given at 13s. 5 $\frac{1}{4}$ d. Coke (from gasworks) is also recommended to English water-gas makers; but if ever the day should arrive when, for heating purposes, gaseous has to take the place of solid fuel, and water-gas has to displace ordinary coal-gas, either raw coal must be employed in the generators, or the great waste of heating-power, already mentioned in coking the coal, must be incurred.

Mr. Kupelwieser properly observes that the cost of water-gas must largely depend on the value which is attached to the producer-gas, and he divides the expense in the following manner:—

	Florins.
29,734,731 cubic metres of producer-gas at '18 kreutzers per metre.....	53,522
6,041,155 cubic metres of water-gas at '673 kreutzers per metre.....	40,653
Total cost.....	94,175

Now, the total weight of combustible matter, viz., carbon, in the producer-gas is, by calculation, 5,898 tons, and its value, based on the price of the cubic metre, is 18s. 1 $\frac{3}{4}$ d. per ton.

The above quantity of water-gas is estimated to contain:—

	Tons.
Carbon	1,619
Hydrogen.....	270
	1,889 valued at 43s. per ton.

If we take 1,000 kilos. as being equal to one ton, the heat from this quantity of carbon, as it exists in the producer-gas, viz., as carbonic oxide, may be stated as representing (1,000 \times 5,600 calories) 5,600,000 calories.

This quantity of heat could be obtained by the combustion of 700 kilos. of carbon (700 \times 8,000) being 5,600,000 calories.

Now this carbon may be taken as probably equivalent to 800. kilos of the small coke, and costing therefore about 8s. against 18s. 1 $\frac{3}{4}$ d. for the same amount of heating power in the form of producer-gas.

The water-gas contains in 1,000 parts:—

	Calories.
857 of carbon, which \times by 5,600 =	4,799,200
143 of hydrogen " \times by 32,180 =	4,633,200
	9,432,400

To produce this quantity of heat from pure carbon we should require $\frac{9,432,000}{8,000} = 1,179$ kilos. of this substance.

If we assume this quantity of carbon to represent 1,350 kilos. of the small coke, this, at 10s., amounts to 13s. 6d., which appears capable of affording the same quantity of heat as 857 of carbon and 143 of hydrogen, costing 43s.

From what has preceded, I have calculated that if a given quantity of heat from coke burnt direct costs 100; that from water- and producer-gases, according to Mr. Samson Fox's estimate of 2s. 8d. for gasification, will be about 120, and, according to Mr. Kupelwieser's, of 13s. 2 $\frac{1}{2}$ d., about 200.

These calculations are my own, worked out upon the figures given by Mr. Kupelwieser, and they both tend to show how largely the cost of fuel was increased at Witkowitz by the process of gasification. This gentleman then goes on to observe that, according to his experience, gas obtained from coal in good producers gives perfectly satisfactory results in open-hearth furnaces, and that in nearly all cases such furnaces are worked more economically with ordinary producer- than with water-gas. At the same time he allows, that which I previously admitted, viz., that for some purposes water-gas may be profitably employed.

From another friend I learn that for each metre of water-gas, four metres of producer-gas have to be made. He would not consider it advisable to convert coal into gaseous fuel for the purpose of raising steam. The producer-gas obtained in manufacturing the water-gas is used in puddling furnaces and in heating large blocks of metal weighing as much as 50 tons. In the open-hearth steel furnaces a mixture of the two gases is employed, and for steel, intended for castings, this mode of treatment is considered very good, because the high temperature afforded by the water-gas, he says, enables the workmen to have the metal so fluid that it runs with ease into castings, however intricate.

(An abstract of the discussion on this paper will appear in the next number of this Journal.)

A New Form of Siemens Furnace, arranged to Recover Waste Gases as well as Waste Heat. John Heald, F.G.S., M. Inst. C.E., and P. Pouff, Ingenieur. A paper read at the Paris Meeting of the Iron and Steel Institute.

BEFORE referring to the special subject of this communication, and in order that it may be the better understood, it is necessary to call attention very briefly to the great advance which has been made in heating and metallurgical operations, as the result of the labours of the late Sir William Siemens and of Mr. Frederick Siemens in connexion with the regenerative gas furnace.

The first idea of applying the regenerative principle for industrial purposes appears to have occurred to the mind of the Rev. Robert Stirling in 1817, who, with his brother, James Stirling, invented a regenerative air engine bearing their name, which worked economically at the Dundee Foundry, and was found to be quite as efficient as the steam-engines of that day. They also foresaw the possibility of applying the regenerative principle to metallurgical furnaces. A more complete form of furnace of the same kind was devised in 1837 by Mr. J. Slater. According to this arrangement, as well as in the earlier form proposed by the Stirlings, only the air supplied to the furnace was to be heated, and solid fuel was intended to be employed. Neither of these proposals, however, led to any practical result, so that they can only be looked upon as mere philosophical ideas or suggestions. The same remark applies also to the later proposal of Mr. R. Laming, who, in 1847, took out a patent for a regenerative furnace embodying the then novel principle of first converting solid fuel into gas, to be burnt in a furnace in combination with air heated by means of the waste products of combustion. This was a further step in advance in furnace construction; but as Laming's invention was proposed for heating gas retorts, and coke was in consequence the fuel intended to be employed, the attainment of only a relatively low temperature was contemplated.

By the light of present knowledge, it is clear that none of these proposals were susceptible of useful application without considerable modification, and there is no evidence of any application of these furnaces having been made before the Siemens furnace was introduced; in fact, it is only recently that the existence of these earlier proposals to apply the regenerative principle to furnaces has been made known; and in spite of them, or perhaps on account of these proposals never having been carried out, Mr. Frederick Siemens and the late Sir William Siemens will ever be regarded as the true inventors of the regenerative gas furnace. They were the first to show, by means of philosophical reasoning, what really could be effected by the application of the regenerative principle to furnaces, and having a clearly defined idea in their own minds of the capability of the valuable apparatus with which they were dealing, they perfected that wonderful invention which may justly be said to have revolutionised the construction of furnaces for high temperatures.

Messrs. Siemens were the first to heat the gas as well as the air supplied to a furnace, utilising its waste heat for that purpose, and to provide for reversing the direction of the

flame in the furnace chamber whereby uniformity of heat and the highest temperatures are attained. They thus rendered possible the carrying out of processes which, until the introduction of their furnace, had only been foreshadowed by chemical research. The great economical idea embodied, and carried out in the regenerative gas furnace, is perhaps best illustrated by comparison with such a meritorious invention as Neilson's hot blast stove. In this case the temperature of the blast was raised by means of fuel separately burned for that purpose, but in the case of the Siemens regenerative gas furnace, the heat below the temperature of the work carried on in the furnace is impounded in the regenerators, and applied to heat up the gas and air supporting combustion. In high temperature furnaces, the heat below the temperature of the work to be performed therein is by far the largest proportion of the total heat produced, and previously to the introduction of the Siemens furnace this heat had been lost by being allowed to pass away with the waste gases to the chimney. This circumstance was clearly explained by Lord Armstrong at the meeting of the British Association at Birmingham in 1865. By heating the inflowing gas and air, the temperature of the flame in a furnace may be raised to almost any extent; in fact, the heat attainable under these conditions is only limited by the power of resistance of the materials of which the furnace is built, and thus the highest temperatures required in metallurgical operations are obtained with facility by the expenditure of a moderate amount of fuel, especially since the introduction by Mr. Frederick Siemens of the method of heating by radiation, by which means the durability of the furnace has been also much increased.

In considering the details of construction of this ingenious apparatus, it occurred to Mr. E. Biedermann and Mr. E. W. Harvey, who are on Mr. Frederick Siemens' technical staff (the former having entered the service of the late Sir William Siemens about thirty-four years ago), that possibly further economy in fuel might be realised by a re-arrangement of some of the parts of the regenerative gas furnace. Their attention was directed to the conversion of solid fuel into gas in the producer, and to the relatively high temperature at which the products of combustion passed from the furnace into the regenerators, as also to the chemical composition of these products, which temperature and gases they thought might be utilised in the gas producer.

In an ordinary gas producer the production of carbonic oxide is effected in two operations; on the grate carbonic acid is formed, in the ordinary course of combustion, and this carbonic acid is afterwards converted into carbonic oxide by taking up another equivalent of carbon, whilst passing through the incandescent fuel in the upper portion of the producer, and in this condition it flows on to the furnace with the other gases distilled from the coal during the process of gasification. It should be remembered, however, that the production of carbonic acid on the grate of the ordinary gas producer is attended with the development of heat; whereas the conversion of carbonic acid into carbonic oxide, in the upper portion, is carried on at the expense of heat.

In the new Siemens furnace, the gaseous products of combustion from the heating chamber of the furnace are delivered under the grate of the producer, these gases consisting of intensely hot carbonic acid, water in the gaseous state, and nitrogen, the production of carbonic acid in the producer may therefore be dispensed with; but in this case the heat attending the production of carbonic acid in the producer has also to be dispensed with. It had therefore to be ascertained whether the products of combustion from the heating chamber would contain a sufficient amount of heat for insuring their conversion into combustible gases. This has been found to be the case in practice with furnaces working regularly for the past six months—a satisfactory result that is probably due to the presence of a large quantity of heated nitrogen in the products of combustion, which, passing through the producer without undergoing chemical alteration, maintains the heat of the fuel. The economy of fuel resulting from the conversion of carbonic acid into carbonic oxide is diagrammatically illustrated by means of the accompanying sketch (Fig. 1) of a gas producer.

Assuming that the producer contains only coke in the incandescent state, this coke if fed with oxygen will produce carbonic acid in the lower zone, which will be converted into carbonic oxide in the upper zone; but if fed with hot carbonic acid, instead of oxygen, one-half the fuel, comprising the lower zone, may be dispensed with, and an economy in weight of fuel to the same extent will be realised.

The furnace about to be described must be clearly distinguished from that class of regenerative gas furnace before referred to as having been first suggested by Mr. R. Launing in 1847, where conduction air regenerators alone are employed. The latter form of furnace is necessarily wasteful in working, inasmuch as in theory it can only utilise about one-half of the total heat contained in the gases leaving the furnace chamber, this being the ratio of the air for combustion to the amount of gases made from coal entering the furnace, and in practice it would fall short of this saving, owing to the class of regenerator employed, in which the heat from one current to another had to be transmitted through brickwork. In the new Siemens furnace, on the contrary, the waste gases are directed, partly through an air regenerator, and partly under the grate of the producer, there to be reconverted into combustible gases, and to do the work of distilling hydrocarbons from the coal; in fact, the gas producer in this case absorbs or utilises the heat formerly deposited in the gas regenerators of furnaces; and in doing this transforms spent gases into combustible gases. It is held as an axiom, and the construction of the new furnace is based upon this consideration, that, besides air regenerators, gas regenerators, or their equivalent in the form of a converter producer, must be provided for absorbing all the heat contained in the gases leaving the furnace chamber. In the converter, the fuel absorbs the waste heat from a portion of the products of combustion leaving the furnace, and at the same time carbonic acid and water-vapour are converted into carbonic oxide and hydrogen. Disregarding the small proportion of water-vapour they contain, the products of combustion from a furnace may be taken as consisting of:—

CO₂, 17 per cent.; O, 2 per cent.; N, 81 per cent.

The 17 per cent. of CO₂, also the 2 per cent. of O, are converted into CO, whilst the nitrogen simply passes through the fuel without change, and serves the useful purpose of maintaining its heat for the conversion of the other gases.

For the propulsion of the gases through the converter, a steam blast is employed. This steam is superheated by the waste gases from the furnace, and mixing with them, forms a very hot blast indeed under the grate. The annexed diagrams (Figs. 2 and 3) show the relation which exists between the ordinary and the new type of Siemens furnace. As will be seen by examining them, the function in both is the same. In the first case, the waste gases are partly directed through two regenerators, while, in the second case, the waste gases are partly directed through an air regenerator and partly through a converter producer. In both cases the waste heat from the furnace is entirely utilised, and the gas and air reach the furnace in an intensely heated condition. In both cases, again, there is a reversal of the direction of the flame in the furnace, which ensures uniform heating of the furnace chamber and the materials contained in it.

This furnace may be constructed in various forms, the one shown in the accompanying diagrams (Figs. 4—8) having been used with success for heating and welding iron. It is a radiation furnace, heated by means of a horseshoe flame; this form of flame offers advantages in this as in ordinary regenerative gas furnaces, but its adoption is not obligatory, as the flame may be made to traverse the heating chamber from end to end in the usual manner. The same letters indicate the same parts in all the figures. AA' are reversible regenerators for air, on the top of which is built the gas producer or converter B, of which FF' are the charging hoppers and XX' the grates. The heating chamber E adjoins the producer resting on the ground, or in some cases a pit may be provided below it. CC' are the flues leading the combustible gas to the furnace chamber E, the passage of the gas in these flues being controlled by the valves DD' at the two ends of a rocking-

beam, so that the outlets are opened and shut alternately to convey the gas to one or other of the ports GG¹ of the heating chamber E. HH¹ are the air ports of the heating chamber, communicating through the flues KK¹ with the regenerators AA¹. II¹ are steam jets placed in the return flues for directing a portion of the waste products of combustion to the grates of the converter. J is the valve for reversing the direction of the air flowing into the furnace, and of the products of combustion through the regenerators to the chimney flue. OO¹ are hinged caps for alternately admitting and shutting off the products of combustion from the heating chamber to the converter. These caps are worked automatically by means of connexions attached to the rocking beam, the same movement which closes D opening O¹, and that which closes D¹ opening O. Qq are doors for giving access to the grates of the converter for clearing them.

The *modus operandi* of the furnace is as follows:—Gas from the converter B passes through the flue C¹ and the valve D¹ to the gas-port G¹, and into the combustion chamber h¹ g¹. Air for combustion passes through the regenerator A¹, the air-flue K¹, and the air-port II¹ into the combustion chamber, where it meets the gas from the converter, and combustion ensues. The horseshoe flame sweeps round the heating chamber E, the products of combustion passing away by the second combustion chamber h, g, and going partly through the regenerator A, and reversing valve J into the chimney flue, and partly down the flue G, whence they are drawn by means of the steam jet I through the capped inlet L under the grates XX¹ of the producer B, there to be converted into combustible gases. From time to time the direction of the flame in the furnace is reversed by manipulating the rocking beam, carrying the valves DD¹, and the reversing valve J in the usual manner of working regenerative gas furnaces. An auxiliary steam jet is provided for the purpose of supplying

atmospheric air to start the producer, when the furnace is first heated up.

The new form of regenerative gas furnace has been applied in this country to the heating and welding of iron, to which uses its application is being extended in England and abroad, whilst furnaces are in course of construction to apply it for puddling iron and for copper and steel melting. Altogether ten furnaces for these purposes are in course of construction, in addition to two furnaces already at work for heating iron.

The first furnace of this kind was constructed at the Pather Iron and Steel Company's Works at Wishaw for welding iron, and much credit is due to the proprietors for having had the enterprise and public spirit to make the first application of this improved regenerative gas furnace. The working has been eminently satisfactory from the commencement. The success of this first application of the furnace proves the correctness of the principle upon which it is constructed, and the means adopted for carrying it out.

The results of working during the past six months have shown an average saving of 5 per cent. in waste on the weight of the iron heated, and a saving of upwards of two-thirds of the weight of coal used, and a greater money-saving, owing to the inferior quality of the fuel employed as compared with that used in their other furnaces fired with solid fuel. From the total saving thus realised should, however, be deducted the cost of raising steam, for which purpose the waste heat of the old furnaces is utilised. Allowing for separate boilers, the saving effected by the use of the new system in a furnace heating eight tons of iron per shift is nearly 18 tons of coal per week, and the money-saving in iron and coal exceeds 1,000*l.* per annum.

This new furnace has also been recently applied for heating billets by the United Horse-Shoe Company, of London, and in this case the results are quite as satisfactory or even better than those just given, as is shown by the accompanying table:—

Date.	Number of Charges per Shift.	Duration of each Shift.	Average Time required for Heating to Welding.	Weight of Billets Heated (30" × 2½" × 2½").	Coal.		
					Weight Used.	Used per Ton of Billets.	Quality.
1889, Sept. 13	11	A.M. P.M. 5.45 to 5.25	21	Tons. Cwt. 8 16	Cwt. 17½	Cwt. 1.9	Newcastle small.
Sept. 14	6	6.0 to 12.15	20	4 16	8	1.7	Newcastle cobbles.
Sept. 16	11	5.45 to 5.30	21	8 16	17½	2.01	{ ½ Newcastle small. ½ London screenings.
Sept. 17	11	5.45 to 5.30	26	8 16	18½	2.03	

It will be noticed from these results that in this furnace 11 charges are made in less than 12 hours, each weighing about 16 cwt., and yielding in the finished state as horseshoe iron 15 cwt., per charge, or 8.25 tons in the day. The amount of small coal used was about 18 cwt. per shift. This is equivalent to $\frac{18}{8.25} = 2$ cwt. per ton of iron heated, which, it will be admitted, is a most satisfactory result; in one case the consumption of coal was even reduced to 1.7 cwt. per ton, each billet coming out at a full welding heat and rolling into a sound bar. The coal used each day is indicated in the table.

The following are analyses of gas made in the converters at Pather and in London respectively:—

PATHER CO., from Wishaw Coal (nuts).		UNITED HORSE-SHOE CO., Newcastle Cobbles.	
CO ₂	4.6	CO ₂	4.5
O	nil	O	nil
CO	23.0	CO	22.5
H total	17.4	H	16.3
C vapour	1.5	CH ₄	2.6
N	53.5	N	54.1
	100.0		100.0

From these analyses it will be seen that the proportion of CO₂ in the gas made in the converters is not greater than that made in the ordinary Siemens producer.

Besides the advantages in the saving of fuel and metal, it is desirable to call attention to the simplicity of design of the new furnace, owing to which its cost of construction is not much greater than that of a solid-fuel furnace, while its cost of maintenance is very much less. The cost of construction of the new furnace is found to be about two-fifths of that of the old form of regenerative gas furnace of the same productive capacity, with separate gas producers and gas regenerators, and the space occupied below ground is also considerably reduced.

A saving of labour attends the employment of the new furnace, as, owing to the producer being connected with the furnace, the same men can attend to both, and the labour of firing is reduced in proportion to the reduced consumption of fuel.

In conclusion, the following advantages may be claimed for the new furnace, as compared with solid-fuel furnaces used for heating and welding iron, viz.:—

A saving in fuel, amounting to, say, two-thirds in weight, after allowing for raising steam in separate boilers, this saving being fully equal to 5 cwt. of coal per ton of iron heated.

A reduction in the waste of iron equal to 5 per cent. upon the weight of metal heated.

A saving in labour and repairs which will probably compensate for the extra cost of the new furnace.

TO ILLUSTRATE MESSRS. HEAD AND POUFF'S PAPER ON "NEW FORM OF SIEMENS FURNACE."

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

Taking a furnace to heat 10 tons of iron per shift, or 110 tons per week, the following calculation gives the money saving realised by the adoption of the new furnace:—

	£	s.	d.
110 tons iron at 5 cwt. per ton = 27½ coals saved at 6s.	8	5	0
110 tons iron at 5 per cent. = 5½ tons iron at 4l.	22	0	0
Being	30	5	0

per week, or say, 1,500l. per annum.

It may be added that the authors had hoped that the application of this furnace to the attainment of high temperatures, such as are required for steel melting, might have been included in the paper, but the furnaces building for this purpose are not yet completed. Should they, however, be working when the paper is read, information with regard to them will be given in the discussion.

PATENTS.

Improvements in Apparatus for Mixing Gases and for Regulating or Controlling the Pressure or Flow thereof. H. T. Hillischer, Vienna, Austria. Eng. Pat. 9150, June 28, 1888. 8d.

To counteract the differences of pressure caused by the varying height of the gas-holder, the inventor employs a running weight dipping in water and of the same sectional area as the dipping portion of the gas-holder. To regulate the supply of a gas under pressure the said gas is admitted by two openings into a cylinder carrying a hollow piston pressed downwards by a spring. One of the openings is entirely below the piston; the other communicates with its interior by a corresponding hole in the piston itself. It will be seen that the greater the pressure of the gas supply, the higher the piston will be forced against the spring, and the more constricted will become the communication between the upper gas inlet and the interior of the piston. The piston rod is also hollow and constitutes the gas outlet. An apparatus for further regulating the mixing of gases consists of a hollow plug formed at the end of a pipe and having two openings, which can be made to communicate in varying proportions with two corresponding openings in the plug casing. Drawings are appended.—A. R. D.

Improvements in or Relating to obtaining more Perfect Combustion in Steam Boiler or other Furnaces and Flues and in Apparatus thereof. A. Francis, Liverpool, and E. Manbré, Garston. Eng. Pat. 11,173, August 2, 1888. 8d.

At various points in the fire flue, jets of compressed air are made to play in a direction opposite to the flow of the gaseous current.—A. R. D.

Improvements in and Relating to Gas and Air Reversing Valves for Regenerative, Smelting, and other Furnaces or Purposes. J. Jardine, Motherwell, and J. Ferguson, Pollokshields. Eng. Pat. 12,318, August 27, 1888. 11d.

This specification is unsuited for useful abstraction. It is accompanied by three sheets of drawings.—A. R. D.

Improvements in Apparatus for Naphthalising or Carburetting Illuminating and other Gas. H. S. Maxim, London. Eng. Pat. 12,518, August 30, 1888. 8d.

The carburetter consists of a chamber fitted with trays, one above another, to contain the carburetting liquid, over-flow arrangements being provided at the periphery and centre alternately. The hydrocarbon is stored in a tank over the carburetter, and the supply is automatically controlled by a valve actuated by the rise or fall of a float situated in the lower portion of the chamber below the trays. The carburetter also contains a system of heating pipes for promoting the evaporation of the hydrocarbon as desired. The apparatus includes a density regulator, consisting of a drum suspended by a spiral spring in a chamber through which the carburetted gas passes on its way to the burners. The bottom part of this chamber is

also connected with the pipe supplying the yet uncarburetted gas by an opening into which fits a plug suspended from the float. When the gas is being over-carburetted, the increase of density causes the float to rise, which, raising the plug with it, admits a diluent in the shape of uncarburetted gas.—A. R. D.

Improvements in obtaining Hydrogen. L. Mond, Northwich, and C. Langer, London. Eng. Pat. 12,608, September 1, 1888. 8d.

If carbonic oxide or gaseous hydrocarbons be brought into contact with metallic nickel at a temperature of 350°—400° C., or with metallic cobalt at 400—450° C., decomposition takes place into carbon and carbonic acid or hydrogen, the carbon combining with the metal. If now steam, at a moderate temperature, be introduced, this carbon combines with oxygen to produce carbonic acid, with simultaneous formation of free hydrogen. These various reactions take place simultaneously when the steam is passed through the apparatus along with the carbonic oxide or hydrocarbon, the ultimate products being carbonic acid and hydrogen. The former can be eliminated by any suitable means, such as by washing with milk of lime. The cobalt or nickel surfaces may be obtained by impregnating pumice stone with a solution of the metal, and reducing.—A. R. D.

An Improved Manufacture of Artificial Fuel and other Moulded Blocks, and Apparatus employed therein. T. L. J. Quemesson, Chauny, France. Eng. Pat. 13,066, September 10, 1888. 11d.

The main feature of this invention is the employment of potters' clay or other plastic earth as the agglomerative agent in the manufacture of moulded blocks. Pitch, tar, resin, &c., may be used as well, but only to increase the combustible qualities of the artificial fuel. The specification also describes and illustrates a set of machinery suitable for forming fire-lighting briquettes.—A. R. D.

Improvements in Apparatus for the Purification of Gas. W. Kusnezoff, St. Petersburg, Russia. Eng. Pat. 13,074, September 10, 1888. 6d.

This apparatus consists of a rectangular metallic casing, divided by a horizontal partition into two compartments, communicating with each other by a vertical duct. The lower one is filled with vertical partitions crossing one another at right angles, forming a large number of vertical channels communicating with each other alternately at the top and the bottom. The upper compartment is also provided with a number of vertical partitions, but these are so disposed as merely to form a serpentine passage for the gas. The upper chamber is filled with water to one-third of its depth. Water stands in the lower chamber also, but not at such a depth as to interfere with the communication between the vertical channels. The apparatus is specially adapted for purifying gas made from crude petroleum.—A. R. D.

Improvements in the Reversing and Regulating Valves of Regenerative Gas Furnaces for Steel Melting and other Analogous Purposes. T. Beardmore, Bothwell. Eng. Pat. 13,770, November 1, 1888. 8d.

The valve is cylindrical with the lower extremity cut away at an angle of about 45°. Both valve and valve-casing have double walls, between which water is made to circulate. For details the drawings which accompany the specification must be consulted.—E. E. B.

Improvements in Producing Water-Gas, and in Apparatus therefor. G. H. Lloyd, Sutton Coldfield; A. L. Lloyd, Leamington; H. Bewlay, Moseley; and W. Seddon, Birmingham. Eng. Pat. 2216, February 8, 1889. 8d.

These improvements have reference to the ordinary process of making water-gas, i.e., by first raising a mass of fuel to incandescence with an air-blast, and then passing steam through the said mass. The producer-gas evolved during the first operation is caused to burn in a tubular-shaped combustion chamber, and then pass through an ordinary regenerator,

which is employed to superheat the steam required for the second operation. By employing a separate combustion chamber there is much less risk of trouble and damage, such as often occurs when combustion takes place in the regenerator itself. The air required for combustion is caused to pass through channels in the brickwork of the chamber, previous to its admission into the latter, at the end farthest from the regenerator.—A. R. D.

Improvements in Gas Producers, Apparatus and Appliances connected therewith, for the Manufacture of Water-Gas and other Gases. W. Deighton, Leeds. Eng. Pat. 6567, April 17, 1889. 8d.

ADJACENT to the producer is situated a space or chamber into which the water-gas is drawn as formed. This chamber may serve not only as a collecting space for the water-gas, but also as a supplementary superheater for the air supplied to the producer. The underside of the producer cover is provided with a kind of water-jacketed retort, through which the fuel is supplied, and where its volatile constituents are distilled off before it is let down into the producer proper. Suitable arrangements provide for the recovery of the tar, ammonia, &c. One of the claims refers to an improved regenerator. This consists of a chamber packed with checkered brickwork, but having a space left for a series of pipes also, through which pass the air and steam required, while the producer-gases play through the checkered brickwork.—A. R. D.

Improvements in the Manufacture of Hoods or Mantles for Burners used in Incandescent Gas-lighting. L. Paget and C. I. Kintner, New York, U.S.A. Eng. Pat. 6805, April 23, 1889. 6d.

THE improvements consist in electrically heating a metallic base or support immersed in a solution of a suitable oxide. The electric current is said to cause an expansion of the pores of the metal, and thus effect an absorption of the oxide. If desired the metallic base may be heated before immersion, and by other means than electrical. In this case the alternate heating and dipping are repeated till the required coating is obtained.—A. R. D.

Improvements in and relating to Machines or Apparatus for Manufacturing Gas. W. Clark, Philadelphia, U.S.A. Eng. Pat. 9288, June 4, 1889. 11d.

THE apparatus herein described is intended to produce a mixture of water-gas and ordinary coal-gas. Coal is carbonised in retorts sloping downwards from the front so that the resulting coke may be pushed backwards into a chamber, whence it passes directly to a generator to be converted into water-gas. The producer-gas obtained during the "blowing up" of the fuel is employed to heat the retorts externally, while the water-gas is allowed to pass through the interior of the retorts and mingle with the coal-gas evolved there. To secure regularity in the process it is preferred to have two sets of retorts and two water-gas producers.—A. R. D.

Improvements in Manufacturing Gas. A. J. Boulton, London. From W. G. Wood, Windsor, Canada. Eng. Pat. 10,256, June 24, 1889. 8d.

A CYLINDRICAL generator is filled with alternate layers of iron filings, zinc turnings, sulphate of copper crystals, and sponge. Dilute sulphuric acid and a suitable liquid hydrocarbon are then introduced, and a gentle current of air is caused to bubble through the apparatus from the bottom. The resulting mixture of carburated air and hydrogen is well adapted for both heating and illuminating purposes. It is advantageous to allow an electric current to circulate through the contents of the generator as the evolution of hydrogen is thereby promoted, and any sulphur that may be present in the hydrocarbon is prevented from passing over into the gas.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Meta-Cresol. A. Claus and A. Dreher. J. Prakt. Chem. 39, 366—373.

METACRESOLPARASULPHONIC acid treated with 1 mol. of bromine to 1 mol. acid yields a monobromo-compound; if in the proportion of 3 to 1, pure tribromo-cresol is formed. The authors, by using 2 mols. to 1 mol. acid, obtained diorthodibromometacresolsulphonic acid—

crystallising in white lustrous plates melting (anhydrous) at 170° (uncorr.) soluble in water and less so in alcohol.

The potassium, barium, copper, silver, nickel, and lead salts are described. The structure of the acid, i.e., the position of both bromine atoms in the ortho-position with regard to the hydroxyl group is proved beyond doubt by the oxidation of the acid to 2:6 dibromotoluquinone melting at 115° (uncorr.). A second metacresolsulphonic acid is obtained, distinguished by its crystallisation, from which an acid potassium salt is prepared by the action of bromine. This reaction points the formula for *m*-cresol-*o*-*p*-disulphonic acid showing—

—D. A. S.

Ozokerite and Petroleum in Galicia. Annales des Mines.

Ozokerite.—The deposits of ozokerite at Boryslaw were recently described by A. Kateau (*see abstract*, Vol. XXVII., pp. 55-56). In an area of about 250 acres, divided among about 1,200 owners, there are from 12,000 to 13,000 pits, of which about one-tenth are now working. The pits are from 3 to 8 yards apart, and each works an area of from 9 to 61 square yards. The pits are square, and ordinarily have a section of about 10 square feet, and when they encounter a vein or bed of ozokerite, a drift is driven on it, if possible into the adjoining property, until it closes by a fall.

The produce is drawn by a jack roll worked by a man or woman. The mortality from accidents is about 2 per cent. per annum.

Great danger arises from inflammable gases, which are inclosed in the strata under great pressure. Mueseler or Marsant lamps are in universal use.

The produce is either pieces of nearly pure ozokerite or earths rich in ozokerite. After the pieces of pure ozokerite are picked out by women, the earths containing 8 per cent. are treated with cold water, and the ozokerite separates, owing to difference of density. After this washing, the earths containing 4 to 5 per cent. are placed in casks and boiled with water, the ozokerite floating to the surface at a temperature of 212° F. It is proposed to treat the residue containing from 1 to 1½ per cent. of ozokerite with benzine, so as to remove the last traces, and remove the benzine by means of steam heating.

The pure ozokerite is melted and run into loaves weighing about 1 cwt. The cost of washing, &c., is about 18 cents per cwt.

Details are given as to cost of working, &c. In 1886, the selling price was from 100 dols. to 125 dols. per ton, and cost of production from 65 dols. to 75 dols., leaving a profit of from 25 dols. to 50 dols. per ton.

The annual production has varied from 4,000 to 18,000 tons, and in certain years the value has exceeded 1,800,000 dols.

Other deposits of ozokerite are found at Truskawiec, Starunia, and Dwniaez, always in Miocene formations.

Petroleum.—The most celebrated petroleum region of the Carpathians is at Slobodarungurska, about three miles from Kolomen. It is probable that oil issues from Eocene formations, although certain geologists consider that they are of Miocene age. The workings are concentrated in a clearing, in the bottom of a valley, and surrounded by the State forests.

Beneath the alluvial deposits of sandy clays, the boreholes traverse a series of beds of shales and sandstones, dipping toward the south-west. The sandstones are the only beds impregnated with the petroleum, and down to a depth of 300 yards there are three of these oil-bearing horizons; the petroleum is also found in the faults.

The mining area covers about 800 acres, and all pits sunk to a certain depth in this area are productive. The oil is worked by means of boreholes, which were first made by hand labour, but the Fabian and Canadian systems of boring are now universally adopted (full details are given of these two systems).

The mean produce of a well is from 25 to 30 barrels per day, and the life of a well is about two years. The holes are usually not less than 20 yards apart. The total production of a well is from 15,000 to 20,000 barrels. The annual production of the district is about 750,000 barrels.

The densities of the oils diminish in depth; when shallow it may be 38°, with 6 per cent. of paraffin; at some depth it may be 35°, with only 1 per cent. On distillation the oil yields—

Benzine	22
Lighting oils	56 to 60
Paraffin	1 to 6
Residues and loss	12

The royalty paid to the owner of the oil is usually 50 per cent. of the produce. The price of a barrel is about 2.50 dols. and in a well with an average output and duration, the gross produce will be worth from 37,500 dols. to 50,000 dols. The cost of boring (9,250 dols.), maintenance for two years (925 dols.), attendance (4,400 dols.), and sundry charges (1,925 dols.), may be estimated at 16,500 dols.

The royalty at 50 per cent. will vary from 18,750 dols. to 25,000 dols., and the net profit from 2,000 dols. to 8,500 dols.

IV.—COLOURING MATTERS AND DYES.

Quinoline Derivatives from Orthonitrobenzoylmalonic Ether.
C. A. Bischoff. *Annalen*, **251**, 360—384.

The author gives two improvements in the preparation of *o*-nitrobenzoylmalonic ether already described (Ber. **17**, 2796). The first consists in estimating exactly the amount of *o*-nitrobenzoylchloride contained in the raw product, by precipitating from the latter any *o*-nitrobenzoic anhydride with ether, weighing this and then calculating the amount of malonic ether (1 mol.) and sodium ethylate (2 mols.) necessary to combine with the chloride remaining dissolved in the ether. When the condensation is complete, the ether and alcohol are distilled off and the malonic ether crystallises out on the addition of dilute hydrochloric acid. The second improvement provides for the separation of the potassium salt from the oily mother-liquors of the crystals of the malonic ether by the addition of strong potash solution. The potassium salt, $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CO} \cdot \text{CK}(\text{CO}_2\text{C}_2\text{H}_5)_2$ crystallises from alcohol in small orange-yellow nodules, and when dissolved in water and precipitated with cold hydrochloric acid yields the ether melting at 54°. The addition of ferric chloride to a solution of the ether in alcohol gives a blood-red colour, and on adding water a brick-red powder separates which is decomposed by acids into the original ether. An aqueous solution of the potassium salt gives precipitates with solutions of most metallic salts. By reducing the ether or its potassium salt with zinc dust and acetic acid at 100°, saturating the solution with sodium carbonate, filtering, neutralising with hydrochloric acid and evaporating in a vacuum, crystals of pure dihydroxyquinoline were obtained of which the properties will be described later. By passing hydrochloric acid gas into a cold solution of the ether in alcohol, together with slips of zinc, it was

possible by fractional crystallisation to obtain a substance melting at 170°, which according to analysis was the body—

or more probably—

α-ethoxy-*γ*-hydroxy-*β*-quinoline carboxylic acid. The substance crystallises from alcohol in thin colourless needles, dissolves in ether and benzene, but is insoluble in water. In a dilute solution it gives a violet colouration with ferric chloride. No other product with a sharply-defined melting point was isolated in the reaction. The substance obtained from the mother-liquor commenced to melt at 139° and finally fused between 147°—150°. By altering the conditions of reduction a number of by-products were formed, the principal fractions melting at 150°, 163°, 167°, and 175°. Although these all crystallise in well defined forms, the author considers them as a mixture of substances of which the most stable decomposition product is dihydroxyquinoline. The preparation of this body is performed as follows:—20 grms. of *o*-nitrobenzoylmalonic ether are dissolved in 200 grms. of 96 per cent. alcohol, 208 grms. of hydrochloric acid of sp. gr. 1.16 are added, and finally 107 grms. of tin. The whole is then heated on the water-bath until the reduction is complete, evaporated and precipitated with water. The tin salt thus obtained is freed from tin by sulphuretted hydrogen in an alcoholic solution which, after filtering, yields dihydroxyquinoline on adding water. The substance has the constitution—

does not melt at 320°, and is identical with that prepared by the action of concentrated sulphuric acid on *o*-nitro-phenyl-propionic acid (Bayer and Bloem, Ber. **15**, 2151), and also by fusing *γ*-bromo- or chloro-carlostyrl with potash (Friedländer and Weinberg, Ber. **15**, 2683). In the preparation just described a small quantity of *α*-ethoxy-*γ*-hydroxyquinoline—

is formed. This crystallises in colourless needles melting at 228°, and is not coloured by ferric chloride. If dihydroxyquinoline be dissolved in cold concentrated sulphuric acid and sodium nitrite solution slowly added a nitroso-derivative is formed which is identical with the oxime obtained by the action of hydroxylamine hydrochloride on quinisatin and having the formula—

(Bayer and Homelka, Ber. **17**, 985).

When the oxime is treated with ammonia in an alcoholic solution, it turns green, and if this solution be warmed with alcoholic ammonium sulphide, the colour changes from pure blue to bluish-violet, then to a deep violet, and finally a brown powder separates. These solutions dye wool or silk dull bluish-violet shades, which are destroyed by acids. The violet solution is the most stable, and when it or the blue solution is evaporated in a stream of carbonic acid, a vermilion-red powder is formed. This can also be obtained by adding strong acetic acid to the violet solution, when a brown powder separates, which is transformed into the red by boiling with ammonia and precipitating with acetic acid. It was purified by treatment with dilute caustic soda, in an excess of which it is insoluble, acetic acid, and water, and finally washed with alcohol and ether, and gave numbers on analysis which corresponded to the formula—

The substance is a colouring matter, and a solution of its sodium salt dyes unmoirated cotton bright orange-yellow tolerably fast to acids. It is decolourised by stannous chloride. The author also mentions that a number of blue compounds may be prepared from dihydroxyquinoline. Their constitution has not yet been determined, but they are probably not allied to indigo, but are supposed to be metallo-organic compounds. He proposes to study the action of nitric acid on dihydroxyquinoline, by which a nitrodihydroxypyridine carboxylic acid is formed, and, further, the reduction of mono-substituted nitrobenzoyl-malonic ether is also to be investigated. By reducing benzyl-nitrobenzoyl-malonic ether, among other substances, an acid is obtained as a yellow flocculent precipitate, which melts at 147°. This ketonic acid—

is to be converted into a β -benzylated quinoline derivative.

—T. A. L.

The "Resinate" Colours. A. Müller-Jacobs. Dingl. Polyt. J. 273, 139—142.

SOME further particulars are given regarding the colour-lakes and varnishes patented by the author (see this Journal, 1887, 138). The lakes are prepared by dissolving 100 parts of pale-coloured resin in a solution of 33 parts of soda crystals in 1,000 parts of water. The mixture is boiled for an hour, after which it is cooled down to about 50° C. by the addition of 1,000 parts of cold water, and then the filtered solutions of such basic dyes as magenta, methyl-violet, brilliant green, auramine, &c. are added. The amount of dye used depends on the depth of shade desired, and varies between 5 and 15 per cent. on the amount of resin. The resin-soup solution must be of the right temperature and degree of concentration when the addition of dye is made, so as to avoid the separation of the colour-bases in the form of resinsates. A slight excess of a dilute solution of a metallic salt is added; in the case of zinc sulphate, 55 parts, dissolved in 1,000 parts of water, are used for the above quantities of resin, &c. The solutions of magnesium salts must be very dilute, since, otherwise, the lake becomes resinous on drying.

The lakes, which are not to be used in the paste form, are thoroughly dried at a temperature of 40° to 50°, or 70° in the case of magnesium lakes. The dried lakes are of an exceedingly fine bright colour. They are not affected by air or moisture, and boiling water fails to extract colouring matter. Weak alkalis and acids are also without action, and strong solutions of hypochlorites act very slowly on them, provided that light is excluded, but, in presence of light, oxidising agents act rapidly. Their solubility in alcohol depends upon the nature of the combined metallic base; magnesium lakes dissolve easily, calcium and barium lakes fairly easily, aluminium and iron lakes only slightly. Benzene, ether, chloroform, light petroleum, and other solvents dissolve them easily. Some of the lakes, those of aluminium for instance, are decomposed when their solutions are kept for a little time, the metallic base separating, but others, such as those of zinc and calcium, keep indefinitely. They resist light fairly well. Lakes made with brilliant green resist badly, but those coloured with auramine, methyl-violet, safranine, chrysoidine, and particularly rhodamine, resist very well. The colours bleach more easily when in combination with aluminium and chromium than with zinc and magnesium.

The action of light renders the lakes insoluble in benzene, liberating the colour-base, which may be extracted with hot water. The solutions of the lakes form good varnishes, whose elasticity and power of endurance are increased by the addition of a little india-rubber or gutta-percha. The following is an example of such a varnish:—30 parts of magnesium lake are dissolved in 80 parts of benzene and 20 parts of chloroform, and the solution obtained mixed with 150 parts of a clear solution of 1½ per cent. of india-rubber in chloroform and benzene.—E. B.

Quercetin and its Derivatives. J. Herzig. Monatsh. Chem. 10, 561—567.

LIEBERMANN and Hörmann obtained from Persian berries a glucoside which they considered to be pure Xanthorhammin. Were this the case, by treatment with acid the glucoside should be split up into isodulcite and rhamnetin, whereas the author finds that on decomposing that substance with acid, and preparing the acetyl derivatives of the dyes which separate, there is sometimes considerable divergence in the properties and composition of the latter from those of acetyl-rhamnetin. The composition of the new acetyl derivative lies between that of acetylquercetin and acetyl-rhamnetin. Now on saponifying the first-mentioned acetyl derivative it is split up into rhamnetin and quercetin, which are readily separated by alcohol, in which the latter is more soluble than rhamnetin.

Persian berries, therefore, contain either the glucoside of rhamnetin or a molecular combination of the glucosides of rhamnetin and quercetin, and this would explain why Schützenberger assumed the presence of two different glucosides in Persian berries which he named α - and β -rhamnin. The author proposes to call the real glucoside of rhamnetin xanthorhammin, and the double compound rhamnin.

Instead of macerating the berries before extracting with alcohol it is better to crush them gently in a mortar, then to filter through a narrow wire-gauze sieve, which retains the seed husks. These latter alone may then be extracted with alcohol, which greatly simplifies the operation. The yield is equally good as if the entire berries be taken, for the glucosides are not contained in the liquid which drains off.—A. R.

PATENTS.

Improvements in the Manufacture of Alpha-Naphthol-Disulpho Acid, and in the Production of Colouring Matters therefrom. H. H. Lake, London. From Leonhardt & Co., Mulheim, Germany. Eng. Pat. 11,318, August 18, 1887 (Reprint). 6d.

HITHERTO no disulphonic acid of α -naphthol has been prepared in a pure state, and the first part of this patent describes the preparation of such an one. One part of α -naphthol is heated with 2—3 parts of ordinary sulphuric acid of 65°—66° B. (containing about 93 per cent. H_2SO_4) for two hours to 125°—130°. The new acid is readily soluble in concentrated sulphuric acid, and is unaltered by boiling with dilute sulphuric acid (H_2SO_4 aq. = 1:3). Its salts are very soluble, and do not crystallise well. When combined with diazo-compounds, it forms colouring matters of orange, red, and violet shades. Nitrous acid produces a nitroso-compound, and this, when nitrated yields a yellow dyestuff. The preparation of this latter is as follows:—40 kilos. of α -naphthol are converted into the disulphonic acid as described above, and a slightly acid aqueous solution of it or of one of its salts is treated with sodium nitrite so long as nitrous acid is absorbed. The nitroso-compound so formed is nitrated by adding 100 kilos. of commercial nitric acid or the corresponding quantity of sulphuric acid and sodium nitrate. The conversion takes place at the ordinary temperature, or the whole may be carefully raised to 50°. The yellow colouring matter precipitates, especially after adding potassium carbonate, when it is filter-pressed and dried.—T. A. L.

A New Class of Derivatives of Alizarin-Blue. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,353, October 5, 1888. 8d.

By the action of sulphuric acid or sulphuric anhydride on alizarin-blue new substances are produced, some of which may be employed as colouring matters. The following names have been given to the products which are successively formed in this reaction. 1. Alizarin-blue sulphuric acid. 2. Alizarin-blue sulphonie acid. 3. Intermediate product. 4. Alizarin blue-green. 5. Alizarin green.

1. *Alizarin-Blue Sulphuric Acid*.—10 parts of dry and finely powdered alizarin-blue are slowly added to 20 parts of fuming sulphuric acid containing 23 per cent. SO_3 . The mixture is then agitated for five hours at 50°, and finally at 15° for a further 12 hours. The melt is then poured into water, filtered quickly, pressed, and the substance converted into its sodium salt. It decomposes readily in an acid solution into alizarin-blue and sulphuric acid when heated, and can be used for dyeing wool with the aid of a mordant.

2. *Alizarin-Blue Sulphonic Acid*.—By increasing the amount of sulphuric acid mentioned in the preceding example to 50 parts, and raising the temperature to about 130°, this sulphonic acid is formed. The melt is poured into water heated to boiling, cooled to 40°, and the product filtered off. It dissolves in alkalis, and also in the bisulphites of soda, potash and ammonia, and may be used similarly to alizarin-blue for dyeing and printing, giving somewhat greener shades.

3. *Intermediate Product*.—This substance is formed by increasing the amount and strength of the sulphuric acid, the temperature being finally raised to 50°. The product is extremely unstable, and the acid solutions when heated are rapidly changed into—

4. *Alizarin Blue-Green*.—This product can also be obtained directly from alizarin-blue by adding 10 parts to 100 parts of fuming sulphuric acid containing 70 per cent. SO_3 . Twice the weight of sulphuric acid of sp. gr. 1.84 is then added and warmed to 60°. The solution turns red, and the reaction is complete when a test with water gives a precipitate which dissolves in sodium carbonate with a blue colour, and forms a bright green solution with caustic soda. The bisulphite compounds may be used in cotton printing, and give greener shades than alizarin-blue or its sulphonic acid.

5. *Alizarin Green*.—This is obtained by the action of sulphuric acid of sp. gr. 1.84 on the preceding compound at about 130°. It is also produced by the prolonged action of sulphuric acid on alizarin-blue. Ten parts of dry powdered alizarin-blue are added to 100 parts of fuming sulphuric acid containing 70 per cent. SO_3 at a low temperature. The mixture is then raised to 50° for about six hours, when 200 parts of sulphuric acid of 1.84 sp. gr. are added, and the temperature raised to 125°. After eight hours the melt is poured into water, heated to boiling, cooled to 40°, and the precipitate of alizarin-green filtered, washed, and pressed. The substance forms fine bluish-grey needle-shaped crystals insoluble in cold water, slightly soluble in hot water, and in alkaline solutions. The salts are insoluble in an excess of a caustic alkaline solution. The bisulphite compounds are soluble, and may be employed in dyeing and printing, giving fast shades considerably greener than those obtained from alizarin-blue.—T. A. L.

New or Improved Manufacture of Azo Dyestuffs. B. Wilcox, London. From "The Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 14,412, October 8, 1888. 6d.

THE colouring matters described dye wool a deep black, and are produced by combining α -naphthylamine with the diazo-compounds of the disulphonic acids of aniline, toluidine, α - and β -naphthylamine, rediazotising the amido-azo-compounds so formed, and combining these latter with phenyl- or tolyl- α -naphthylamine. The following example shows the quantities employed. 23.3 kilos. of p -amido-benzene disulphonic acid are diazotised and treated with a hydrochloric acid solution of 20 kilos. of α -naphthylamine. A deep red solution of the amido-azo-compound results, and this is diazotised with 10 kilos. of sodium nitrite in 100 litres of water. The diazo-compound separates out, is filtered off, and added to an alcoholic solution of 35 kilos. of phenyl- α -naphthylamine. The whole is allowed to stand 20 hours, when the acid of the dyestuff is filtered off. By dissolving in an alkali it is converted into a salt which can be separated by salting out. The dyestuff, as already mentioned, dyes wool directly, with the addition of common salt, a deep black shade.—T. A. L.

The Production of a Yellow Colouring Matter from Carbazol. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,478, October 9, 1888. 6d.

THE colouring matter is produced by combining one molecule of diazotised diamido-carbazol with two molecules of salicylic acid. The quantities are given as follows: 50 kilos. of diamido-carbazol sulphate are mixed with 60 kilos. of hydrochloric acid of 1.16 sp. gr., 1,000 litres of water, and 1,000 kilos. of ice. This is then diazotised with 50 kilos. of sodium nitrite in 150 litres of water, and the whole is run into 2,000 litres of water containing 47.5 kilos. of salicylic acid and 150 kilos. of sodium hydrate of sp. gr. 1.38. The mixture turns an intense red, and after standing becomes yellowish-brown. It is then boiled, and the dyestuff precipitated by the addition of salt, when a brown crystalline precipitate is obtained. Hydrochloric acid precipitates the acid from solutions of its salts as a dark bluish-green precipitate, which dissolves in concentrated sulphuric acid with a bright bluish-purple colour. The dyestuff gives yellow shades on unmordanted cotton from an alkaline bath, and dyes wool from a neutral or acid bath with or without the use of mordants.—T. A. L.

The Production from Carbazol of a New Derivative to be Used in the Manufacture of Colouring Matters. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,479, October 9, 1888. 6d.

THIS patent describes the formation of dinitro-carbazol, which on reduction yields diamido-carbazol. 10 kilos. of carbazol and 50 kilos. of glacial acetic acid are warmed to about 80° and treated with 13 kilos. of nitric acid of sp. gr. 1.38, the whole being thoroughly agitated. The temperature is then raised and kept for half an hour at 100°. On cooling, dinitro-carbazol separates out as a yellow crystalline powder. For obtaining diamido-carbazol any reducing agent may be employed, but preference is given to zinc dust in presence of caustic alkalis. 65 kilos. of dinitro-carbazol are mixed with 300 litres of water and 100 kilos. of zinc dust. The mixture is heated to 50°, and 250 kilos. of sodium hydrate of sp. gr. 1.38 are gradually added. The temperature is then raised to 90° for about eight hours until the reduction is complete, or nearly so. 1,000 litres of water are then added and the undissolved residue, consisting of diamido-carbazol, zinc dust and oxide of zinc, is filtered, washed and treated with 500 kilos. of hydrochloric acid of 1.16 sp. gr. This forms a mixture of diamido-carbazol hydrochloride and its zinc chloride compound, which can be filter-pressed. It may be further purified by dissolving it in 1,500 litres of water, decolourising the solution with animal charcoal and adding sodium sulphate to the filtered solution. This precipitates diamido-carbazol sulphate in crystals which is almost insoluble in pure water, but readily soluble on the addition of a mineral acid. On adding an alkali the base is precipitated in silvery white laminae sparingly soluble in water, and not fusible at 250°.—T. A. L.

The Production of New Yellow Dyestuffs called Thioflavines. G. Pitt, Sutton. From L. Casella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 14,884, October 16, 1888. 6d.

WHEN p -toluidine is heated with sulphur it yields bases containing sulphur, and these when converted into their methyl, ethyl or benzyl derivatives give yellow colouring matters. The following example illustrates the method employed: 24 kilos. of the sulphur base from p -toluidine are heated in an autoclave with 30 kilos. of methyl alcohol and 12 kilos. of hydrochloric acid of 1.16 sp. gr. for 12 hours to 170°. The whole is then boiled with water, when part of the product dissolves, and after filtration is precipitated by the addition of salt. This forms a basic colouring matter which dyes cotton, mordanted with tannin and tartar-emetic, a bright yellow. It belongs to a group of colouring matters to which the name Thioflavine T is

given. 25 kilos. of the product insoluble in water are dissolved in 70 kilos. of sulphuric acid. 10–12 kilos. of sulphuric acid containing 60 per cent. SO_3 are added, and the whole raised to 80° . When the sulphonation is complete the melt is poured into cold water which precipitates the sulphonic acid. This is dissolved in an alkali and precipitated with salt and dried. The new colouring matter belongs to the group Thioflavine S, and dyes unmooranted cotton a bright yellow from an alkaline bath. Dyestuffs belonging to the Thioflavine S group may also be obtained by alkylating the sulphonic acids of the sulphur bases from *p*-toluidine.—T. A. L.

The Manufacture of Derivatives of Alizarin-green, suitable for Dyeing and Printing. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 15,121, October 20, 1888. 6d.

This is a continuation of the Eng. Pat. 14,353 of 1888, (page 770), and describes the production of alizarin-green sulphonic acid and alizarin indigo blue by the further action of fuming sulphuric at a high temperature either on alizarin-green or on alizarin-blue as already described.

—T. A. L.

Process for Production and Treatment of Oxidisable Derivatives of Orthonitrobenzylchloride. E. Fischer, Stuttgart, Germany. Eng. Pat. 15,179, October 22, 1888. 6d.

By treating *o*-nitrobenzylchloride with ordinary oxidising agents either no reaction takes place or the decomposition is carried too far, whereas when *p*-nitrobenzylchloride is so treated it is converted into *p*-nitrobenzaldehyde. If, however, the chlorine in *o*-nitrobenzylchloride be first substituted by boiling with sodium acetate and alcohol, the acetate so formed yields on oxidation *o*-nitrobenzaldehyde. This product has given the best result, but in place of sodium acetate, salts of benzoic acid, oxalic acid, formic acid, or thiosulphuric acid may also be employed. The following quantities are given for working the invention: 100 parts of *o*-nitrobenzylchloride, 60–70 parts of fused sodium acetate, and 360 parts of alcohol are boiled for about 80 hours with an inverted condenser. The sodium chloride which separates out is removed and the spirit distilled off, the residue being stirred up with a small quantity of cold water, when *o*-nitrobenzalacetate is obtained as a white crystalline mass, readily soluble in alcohol and ether, less soluble in cold benzene. To convert it into the aldehyde, 100 parts of the acetate are boiled with 250 parts of lead peroxide paste containing 51.3 per cent. PbO_2 and 250 parts of water. After boiling six hours 150 parts of 40 per cent. acetic acid are slowly added, and after further boiling for several hours the whole is filtered, when, on cooling, *o*-nitrobenzaldehyde separates out, and is purified by known methods. Other oxidising agents, such as manganese peroxide, potassium bichromate, or nitric acid may also be employed.—T. A. L.

Improvements in the Production or Manufacture of Diazo-Dyestuffs. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 15,258, October 23, 1888. 6d.

The colouring matters described, which may be considered as azo-derivatives of symmetrical diphenylurea, are obtained by the action of phosgene, thiophosgene, carbon bisulphide, aldehydes, ethylenedibromide, or the ethers of dibasic acids, such as oxalic acid, on *p*-amido-azo compounds, such as *p*-amido-azo-benzene-azo-salicylic acid. These compounds may be obtained by reducing the corresponding nitro-compounds, or amido-diazo-benzene (Griess, Ber. 17, 603) may be combined with salicylic acid. It is found, however, that the best result is obtained by starting with diazo-acet-anilide (Nietzki, Ber. 17, 343), according to the following example: 15 kilos. of finely-powdered acetyl-*p*-phenylene-diamine are dissolved in 45 kilos. of 32 per cent. hydrochloric acid, 200 litres of water, and cooled by the addition of 200 kilos. of ice. The solution is diazotised by adding 7 kilos. of sodium

nitrite dissolved in 21 litres of water. The diazo-solution thus obtained is run into 300 litres of water containing 15 kilos. of salicylic acid, 45 kilos. of calcined soda, and 150 kilos. of ice. The crystalline azo-compound separates after standing 24 hours, when it is filtered and pressed. Without drying, it is then heated with 200 kilos. of ordinary sulphuric acid to 100° for four hours and poured into water, when the amido-azo compound separates as a fine brown crystalline precipitate, which is filtered off. In order to convert it into the new dyestuff it is mixed in a lead-lined vessel with 1,000 litres of water and 700 kilos. of ice, and is converted into its sodium salt by carefully adding a solution of soda or soda lye. Phosgene is then passed in under constant agitation until the solution is acid. The colouring matter, which separates out as a brown precipitate, is filter-pressed, and dried with sufficient calcined soda at 100° to produce the sodium salt. This forms a brownish-yellow powder, easily soluble in water, and dyes unmooranted cotton yellow from an alkaline bath.—T. A. L.

The Preparation of Derivatives (Nitro and Amido) of Alizarin-Mono-Sulpho-Acid, and of Dyestuffs therefrom. B. Willeox, London. From "The Farbenfabriken vormals Friedrich Bayer and Co.," Elberfeld, Germany. Eng. Pat. 15,260, October 23, 1888. 6d.

This invention relates to the production of a monosulphonic acid of alizarin-blue by heating amido-alizarin sulphonic acid in presence of nitro-alizarin sulphonic acid, together with glycerol and sulphuric acid. The alizarin-mono-sulphonic acids required for making these nitro-compounds are obtained by decomposing incomplete melts of flavo- or anthra-purpurin with mineral acids and filtering the product whilst hot. The soda salts of the sulphonic acids, together with about 12 per cent. of flavo- or anthra-purpurin, are salted out from the filtrate after cooling. In order to purify the alizarin monosulphonic acids further, either the aqueous solution is extracted with ether or the dry mixture, after the salting out, is extracted with alcohol. The further treatment is then as follows:—50 kilos. of dry alizarin monosulphonic acid are dissolved in 100 litres of water, 200 kilos. of glacial acetic acid are added, and the mixture cooled to 40° , when 25 kilos. of sodium nitrite are added. The reaction is complete when a test gives a brownish-red precipitate on the addition of an excess of soda lye. The whole is then poured into water and precipitated by salting out the yellowish-red nitro-compound. It is purified by dissolving in hot water, and adding an excess of soda lye. On cooling, the neutral salt of the nitro-compound separates as a dark-coloured crystalline precipitate. The substance is reduced by dissolving 10 kilos. of it in 50 litres of water, and an equal weight of fuming hydrochloric acid, raising the solution to the boil, and adding 20 kilos. of stannous chloride. The reduction is complete when a test dissolves in an alkali with a blue colour. The amidosulphonic acid is precipitated from an alkaline solution as a brownish-yellow crystalline precipitate, slightly soluble in water and insoluble in dilute acids. For converting it into alizarin-blue monosulphonic acid, 20 kilos. of the amidosulphonic acid are mixed with 10 kilos. of the nitro-compound above described, 30 kilos. of glycerol, and 150 kilos. of 66 per cent. sulphuric acid, and heated to 130° , until a test dissolves in alkali with a pure green colour. The melt is then poured into water, filtered and purified by conversion into its sodium salt. It may be employed directly for cotton printing, or converted into the bisulphite compound by heating to 50° a mixture of 10 parts of a 20 per cent. paste of the acid with 10 parts of water and 6 parts of sodium bisulphite of 30°B . The solution obtained is diluted with water, and the bisulphite compound precipitated by the addition of salt.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENTS.

Improvements in the Treatment of Rhea, Ramie, and other Grasses, and in Apparatus therefor. H. H. Doty, London. Eng. Pat. 11,704, August 14, 1888. 8d.

This invention relates to a method of "retting" rhea, flax, &c. It consists in exposing the material to an acid fermentation bath, obtained by dissolving brown sugar, molasses, or cane juice in water, for three or four days at a temperature of about 100° F.

The specification is accompanied by descriptive drawings of the necessary apparatus.—E. J. B.

Process and Apparatus for Treatment of Textile Plants. L. de Kien, Courtrai, Belgium. Eng. Pat. 14,100, October 1, 1888. 6d.

THE inventor claims "the method of treating textile plants so as to clear their fibres, by drying the stems and passing them between an upper and lower set of rollers having projecting blades."—E. J. B.

Improvements in Apparatus for Cleansing Wool and like Materials. I. Singer and M. W. Judell, London. Eng. Pat. 14,247, October 3, 1888. 8d.

THE present invention relates to certain improvements in the system of cleansing wool described in Eng. Pat. 2532 of 1888. The improvements consist of (1) an automatic apparatus for discharging either water or bisulphide of carbon; (2) an arrangement for drying the washed wool (see this Journal, 1889, 28); and (3) to an apparatus for drying the sludge which falls to the bottom of the solvent cells. The sludge is fed into one end of a cylinder surrounded with steam, and is carried forward to the other end, where it is discharged by a worm, the axis of which is hollow and heated with steam.—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

PATENTS.

Improvements in Apparatus for Dyeing and similarly Treating Textile and Fibrous Materials in all Stages of Preparation. W. E. Heys, Manchester. From C. Vandermeersch, Paris, France. Eng. Pat. 13,175, September 12, 1888. 8d.

THIS apparatus consists of a dyebeck containing a drum or hollow cylinder furnished with two shafts which rotate in stuffing boxes in the sides of the trough. One shaft is solid and connected up with any suitable arrangement for driving. The other shaft is hollow and connected by a pipe with the bottom of the dye vat. On the surface of the hollow drum and opening into it are a series of tubular seats upon which are screwed moveable vessels containing the material to be dyed or otherwise treated. The vessels are perforated at the bottom and are supplied with covers which are also perforated, the covers likewise being provided with a screw-thread, so that these dye-vessels may be turned and screwed on to the hollow cylinder in a reversed position. The dye-vessels participate in the rotary motion of the drum and plunge successively into the bath on one side and emerge by degrees from the other side in a continuous circular direction. By means of a pump the dye-liquor is also drawn from the bottom of the vessel and forced into the hollow drum and through the material in the dye-vessels. The primary circulation thus established is combined with the progressive emergence of the vessels from the bath, and the consequent reverse pressure of the liquid above the level of

the bath causes it to spread in a radial direction and so ensures level dyeing. After the operation is half through each of the dye-vessels is unscrewed and inverted, so that for the rest of the operation the liquor passes through the dyestuff in a direction the reverse of that which it has followed in the earlier part of the treatment.—W. E. K.

Machinery or Apparatus for Scouring and Washing Skins and Wool and Analogous Materials. T. Burns, Edinburgh. Eng. Pat. 2311, February 9, 1889. 8d.

THIS invention relates to machinery for facilitating the scouring and washing of skins, wool, and similar materials. A large oblong trough having water flowing through it has working in it in different positions a number of pairs of wooden rollers, or squeezers, covered with some yielding material. The rollers being capable of adjustment any desired pressure can be applied on the skins. The skins to be operated upon are carried on an endless band between the squeezers, and are kept in position by an arrangement of endless ropes, or the feeding may be effected by a number of small rollers mounted in the spaces between the squeezers. The whole series of squeezers, band or rollers, can be actuated in any suitable manner.—E. S.

Improvements in Producing Parti-Coloured Prints or Impressions, and in Apparatus therefor. W. P. Thompson, Liverpool. From P. J. Haase, Mayence, Germany. Eng. Pat. 4456, March 14, 1889. 6d.

THE object of this invention is to produce in a single impression and with one and the same block a parti-coloured print. To effect this, one portion of the block is cut from a porous substance (as wood, pumice stone, or preferably the root of the nut tree or rattan). The nature of the colours employed for the porous part must differ from the rest of the block; that is, if the latter be supplied with ordinary black printing ink or other oily substance the former must be supplied with water-colours, or *vice versa*, so that they will not run into each other. The blocks are fixed in pans in which the colour suitably diluted is placed, and different colours in the pans may be kept separate by suitable divisions. The blocks are surrounded and held in position by a small rim which takes up the black colour from the ink roller and thus marks a black border round the type or picture; the coloured ink in the pan is sucked up by capillary attraction through the pores of the material of which the block is made, and forms on its surface a layer of water or oil colour which yields the desired impression.—W. E. K.

Improvements in or Relating to Machinery or Apparatus for Scouring and Washing Skins and Wool and Analogous Materials. T. Burns, Edinburgh. Eng. Pat. 11,133, July 10, 1889. 6d.

THE improvements refer to the apparatus described above in Eng. Pat. 2311. Here the rollers are placed at one end of the trough, either directly or attached to it by brackets bolted on. The rollers are dissimilar, one being spurred or grooved along its length, and about 12 inches in diameter, two others being similar but smaller, and the remainder plain. The skins being lifted from the trough and placed on the large roller, the spurs tend to pull them on to the other rollers, from which they fall on to an endless band which conveys them to the washing machinery. In cases where sheepskins which have been treated with lime or other substances on their flesh side are to be washed, another spurred roller working in the opposite direction is placed across the trough in front of the entering rollers, and scrapes the lime off while the skin is passing over it.—E. S.

VII.—ACIDS, ALKALIS, AND SALTS.

Lead needed for Vitriol-Chambers. F. Bode. Zeits. f. angew. Chem. 1889, 357.

In the case of three vitriol works of the author's design, the lead used was distributed as shown by the appended table:—

	A.	B.	C.
Capacity of chambers..... Cub. m.	5,800	4,550	2,265
Lead used..... Tonnes	238·0	160·0	96·2
This was disposed thus:—			
(a) Chambers and tubes..... Per cent.	78·3	82·3	73·2
(b) Towers..... „	14·0	11·2	16·2
(c) Remaining plant..... „	7·7	6·5	10·6

If one take the quantity of lead requisite for making the actual surface of the lead chambers without considering that needed for internal fittings, as unity, one finds the weight needed for the various parts (reckoning the metal to weigh 32·5 kilos. per sq. m.) become:—

	A.	B.	C.
(a) Chambers.....	1·40	1·37	1·33
(b) Towers.....	0·25	0·19	0·29
(c) Remaining plant.....	0·14	0·13	0·18
Total.....	1·79	1·69	1·80

With regard to the item C (b) it must be mentioned that this includes some lead pans heated by the waste furnace heat, and so situated before the Glover tower; on the other hand such pans as were heated by steam or directly by coal are omitted.

Strict comparison is not possible between these three sets of figures as the design was not identical for all; such differences largely depend on the view taken by the manufacturer in erecting them according to whether an apparatus of low first cost is aimed at, or one in which stoppage for repairs may be avoided—objects mutually contradictory. The author is of opinion that with care the ratio of the quantity of lead necessary for the chambers to that calculated from their actual dimensions may be brought as low as 1·25 to 1. By the collection of such data as these and their systematic study, it will become possible by simple means to arrive at a fairly accurate estimate of the quantity of lead needed for chambers of any given design.—J. B.

The Oxides of Manganese obtained in the Wet Way.

A. Gorgen. Bull. Soc. Chim. [3] 1, 605–612.

WHEN caustic potash or soda, free from carbonate, is added to an excess of a solution of a manganese salt, and the resulting manganous hydrate is agitated in contact with air for a fortnight, an amorphous hydrated superoxide is formed having the composition $\text{MnO}_2 \cdot 2 \text{MnO}$, and which appears to be a definite compound of the protoxide of manganese and manganous acid. Ammonia produces the same compound, and if the oxidation be carried out on the water-bath the composition of the product is the same. In an atmosphere of oxygen the oxidation is effected three times more rapidly, and the hydrated superoxide, which is brown and amorphous, contains a little more oxygen than is required by the above formula. If an excess of alkali be employed the hydrate oxidises more rapidly and more completely; in presence of an excess of baryta water, a product containing from 50–93 per cent. of MnO_2 results.

Neutral aqueous solutions of manganous salts when allowed to stand exposed to the air become turbid and deposit a superoxide of a brown colour and containing varying amounts of water of hydration. This decomposition takes place slowly in the dark, more rapidly in diffused light, and very quickly in sunlight. The more dilute the solution is and the weaker the acid with which the manganese is combined, the more rapidly does the oxide separate. The chloride and acetate of manganese deposit an oxide $\text{MnO}_2 \cdot \text{MnO}$, the nitrate an oxide $3 \text{MnO}_2 \cdot 2 \text{MnO}$, both of them containing varying amounts of water. Aqueous solutions of the chloride, bromide, iodide, sulphate or nitrate of manganese are not decomposed by boiling, but a solution of the acetate is, and a brown amorphous hydrate, $\text{MnO}_2 \cdot 2 \text{MnO} + x \text{H}_2\text{O}$ is precipitated.

A solution of iodine in potassium iodide has no action upon the above salts of manganese even after being in contact for six months. Chlorine water added to manganous hydrate suspended in water, oxidises it partially to a hydrate, which when dried at 120° has the composition $\text{MnO}_2 \cdot 2 \text{MnO}$. (The unaltered manganous hydrate was separated by dissolving in ammonium chloride.) Manganous acetate is decomposed by a current of chlorine, and manganites having the approximate compositions $3 (\text{MnO}_2) \cdot \text{MnO}$ and $5 (\text{MnO}_2) \cdot \text{MnO}$ result. Manganous carbonate is slowly acted upon by chlorine water, carbon dioxide being liberated and a manganite, $\text{MnO}_2 \cdot \text{MnO}$, formed; by the further action of chlorine a product having the composition $4 (\text{MnO}_2) \cdot \text{MnO}$, or $5 (\text{MnO}_2) \cdot \text{MnO}$, results. The mother-liquor at this stage is neutral and the whole of the chlorine is combined as manganous chloride, but if the addition of chlorine water be now continued, free hydrochloric acid is formed and the liberated oxygen slowly transforms the manganite into manganese dioxide. Bromine acts similarly to chlorine but more slowly (this Journal, 1889, 541).

Composition of Roumanian Rock Salt. Istrati. Bull. Soc. Chim. [3] 2, 4–8.

THE deposits of rock salt found in Roumania on the south side of the Carpathian Mountains occur in eocene and miocene strata, generally at a depth of 33 to 83 feet below the surface and in a few districts as an efflorescence on the soil. There are five mines, four of which belong to the State. These last produced 65,395,204 kilos. of salt in 1878, and 84,176,600 kilos. in 1888, of which more than a quarter is exported at 42–45 fr. per kilo. to Bulgaria, Servia and Russia. The deposits, which are of a very uniform nature even to a depth of 1,300 feet, consist of white and grey salt; coloured varieties are very rare. In many cases petroleum is found near the rock salt deposits, and some varieties of the salt of third quality have a distinct smell of petroleum which is removed by pulverising and subsequent warming to 50°–60° C. The salt is very pure. It contains from 99·161 per cent. to 99·924 per cent. of sodium chloride, only in three out of 13 samples analysed is there less than 99 per cent., and in these cases the figures are 98·052, 98·663, and 98·689 per cent. Potassium salts are absent; five of the 13 samples contain sodium sulphate varying from 0·006–0·174 per cent.; the sulphate of calcium varies from 0·101 to 0·903 per cent., the water from 0·024 to 0·304 per cent., and the insoluble residue (argillaceous matter, calcium carbonate, and carbonate of iron) from 0·034 to 0·764 per cent. The salt is rich in gas and contains from 11·36 to 29·84 cc. of gas per kilo., in one case (purest salt from Slanik mine) reaching 117·23 cc. This gas consists of about 25 per cent. of unsaturated hydrocarbons, 20 per cent. of free oxygen. There is no carbon dioxide. It is sufficiently abundant to give rise to small explosions at times.—C. A. K.

Suggestions for Improvements in the Manufacture of Sulphuric Acid. G. Lange. Zeits. f. angew. Chem. 1889, 385–390.

THE recent researches of Schertel and Sorel (this Journal, 1889 283) have sufficiently shown the advantage of a multiplication of solid surfaces within the reaction chamber. Sorel

has shown that the cooling of these surfaces is an additional factor of great importance. The introduction of lead plates into the chamber, as proposed by Thyss, appears to have failed in producing the expected result, and, in addition, the exposure of the metal to the gases without cooling has been found to be attended with rapid disintegration. The author proposes, as a practical solution of the problem, the construction of such plates of a resistant material, and as the cooling agent, the evaporation from them of the water required in the reaction. The arrangement of a column of perforated porcelain plates patented by himself in conjunction with Horstmann, he now shows to fulfil all the necessary conditions of maximum contact of gas and vapour, with the means of securing the optimum of temperature and condensation. The construction of the "Plattenthurm" is shown in the annexed figure.

The chamber is lead-lined, and each plate is separately supported. The entrance and exit of gases at *g* and *h* and the introduction of liquid from the reservoir *f*, through *d*, need no particular description. The efficiency of a tower of this form would probably be ten times that of a coke tower of equal capacity and entirely free from the objection of a prejudicial chemical action on the nitrous gases (Chem. Ind. 1885, 2). The working advantages of the construction are obvious. The effect of the tower in concentrating the reaction area will be to raise the

temperature presumably much above the optimum. To maintain the optimum, and at the same time take advantage of the heat evolved, the plates will be "irrigated" with water or dilute acid in suitable quantity. It is probable that all the water necessary for the reaction could in this plan be introduced as such and without subdivision or vaporisation. The system is likewise theoretically adapted to promote the efficiency and economy of the action of the nitrous gases, as regards the non-formation of nitrous oxide and the production of a nitrogen free chamber acid.

The probability of a considerable reduction of the reaction area has long been foreshadowed in the statistics of the working of the Glover towers. The percentage conversion of sulphur in these towers may be taken at 9-16, and the reaction is effected therefore in $\frac{1}{10}$ of the volume provided in the chambers. With regard to the heat of reaction available for water evaporation, it may easily be calculated that the formation of 98 parts of monohydrate, at the concentration of chamber acid, liberates the heat necessary for the evaporation of 100 parts water at 100 °C. This proportion of water would be some 25 per cent. in excess of the requirements of the process, but taking into account the losses due to radiation, &c., there appears to be the promise of a nearly self-contained equilibrium.

In regard to the practical steps necessary to test this system, it would be expedient in the first instance to introduce a "Plattenthurm" between two chambers, the steam evaporated being used up in the second chamber. The ideal disposition, however, would probably be the following: After the Glover tower a small chamber 16 by 16 by 40 feet; one or more plattenthürms (3 feet diameter with 25-40 plates requiring a height of 13-20 feet); a second chamber and tower; an end chamber for drying the gases, and lastly a Gay Lussac tower, to which function the plattenthurm is well adapted.

In conclusion the author records his opinion that the early stages of the reaction are best carried out in a small lead chamber; the point when the reaction-curve begins to flatten being that at which the plattenthurm will be found to be the effective substitute, and that at which, therefore, in the future it will come to be inserted. By the flattening of the curve representing the reaction, of course, the slackening of that reaction is indicated.—C. E. C.

On the Inter-Diffusion of Acids and Bases. J. Stefan. Monatsh. Chem. 10, 201-219.

AN account of experiments made to ascertain the rate of diffusion between acids and bases in aqueous solution. The apparatus consisted of two similar thick-walled glass tubes, each 12 cm. in length, 7 mm. inside diameter, and 23 mm. outside diameter, and closed at one end with a cemented glass plate, the other end being ground smooth. After being filled with the solutions, the tubes are placed vertically in a stand, the open ends brought together and glided into position so that the surfaces of the columns of liquid are in contact. A millimetre scale is etched on each tube. Hydrochloric acid and ammonia were the typical acid and base chosen for experiment, but the diffusion coefficients of other acids and bases were also determined. Various strengths of solution were used, but considerable dilution was favourable to uniform results, and it was always necessary to have the denser solution in the lower tube, to avoid interference by the action of gravity. The solutions were coloured with litmus and the progress of the sharp boundary between the blue and red served to mark the rate of diffusion, or rather the extension of volume of the stronger solution, for when the acid was in excess the red colour extended upwards, and when ammonia was in excess the blue travelled downwards. When one molecule of hydrochloric acid was opposed to 1.8 molecule of ammonia, the line of demarcation between the red and blue remained in one position, the diffusion of acid and base being equal. When a normal solution of hydrochloric acid (36.5 grms. HCl per litre) was opposed to a one-sixteenth normal solution of ammonia, the red colour marking the acid territory rose in one hour 8.2, in four hours 16.5, in nine hours 24.5 mm.

With the same strength of acid but a one-fourth normal solution of ammonia, the growth of the acid solution in the same periods was 5.0, 9.9, and 14.7 mm. When both solutions were of normal strength the increase was only 1.2, 2.3, and 3.5 mm. in the same times. The rate of increase is thus always proportional to the square root of the time reckoned from the commencement of the process, and is less as the relative strengths of the solutions approach a certain ratio which in the present case is 1 to 1.8. The chemical attraction of the acid and base exercise no influence on the rate of diffusion. For simplicity the diffusion is spoken of as taking place only in one direction, the inter-diffusion which is constantly in full operation being left out of account; but the whole of the conditions are considered with the aid of mathematics in a further part of the paper which should be consulted for further particulars. Reference is made to the work of L. Chabry and of J. Coleman in similar directions.—G. H. B.

PATENTS.

Manufacture of Chlorine and Hydrochloric Acid.
D. Gamble, St. Helens. Eng. Pat. 11,581, August 11, 1888. 8d.

THE specification describes a process and an apparatus for the production of chlorine and hydrochloric acid from the mixture of chloride and oxide of magnesium as formed in the Weldon-Pechiney process. This mixture is to be heated in a revolving furnace in the presence of a current of highly heated air, and the resulting gases are led off to be treated in the usual way for the separation of chlorine and hydrochloric acid. According to one method the solid substance is filled into a revolving furnace and subjected to a preliminary drying. The hydrochloric acid is given off chiefly during the drying, and the gases are treated for its recovery on their escape from the furnace. The substance when dry is subjected to the action of air at a higher temperature such as is obtained by a Siemens or Cowper stove, and this operation is continued until the evolution of chlorine has ceased. Another arrangement is illustrated in the accompanying sketches. There are two revolving furnaces, A and

Fig. 1.

B, both of which are supported and driven in the usual manner. The material is first charged into the drying cylinder B, and then it is transferred by gravity into the heating cylinder A. This heating cylinder is divided by an annular transverse partition J, and the two divisions thus formed are charged alternately. The hot air first goes into the division which has been charged the longest and then into the other one; it afterwards passes through the drying

furnace when its temperature has been reduced. In the accompanying figures there is shown a system of pipes, H, G, by means of which the hot air is distributed. By means of the valves H the air may be caused to enter at either end of A and to pass thence to the cylinder B. The baffle plates E are placed opposite the openings of the pipes G, in order to diffuse the air throughout the cylinders. The discharging holes C and C' are arranged to come opposite the holes

Fig. 2.

transferred from B to A. Openings are also provided in the ends of the cylinder B to facilitate the discharge. Another apparatus is also described in the specification. It consists essentially of a revolving furnace 40 ft. long by 6 ft. in diameter, and lined with fire-bricks. The material is fed in at one end and discharged from the other, the longitudinal motion being obtained by means of a helical line of fire-bricks projecting from the internal surface of the furnace. Claims: (1) The improvement in the manufacture of chlorine and of hydrochloric acid respectively, which consists in treating a mixture of chloride of magnesium and oxide of magnesium by heated air or by heated air and steam in a revolving furnace or a series of revolving furnaces substantially as described; (2) In the treatment of a mixture of chloride and oxide of magnesium for the purposes described, the application of one or more revolving furnaces fitted with a helical line of breakers; (3) In the treatment of a mixture of chloride and oxide of magnesium for the purposes described, the application of a series of revolving furnaces with or without vertical, transverse, annular partitions, all these furnaces being connected together in such a manner that the same portion of air passes through all of them in succession; (4) In the manufacture of chlorine or hydrochloric acid from a mixture of chloride and oxide of magnesium and heated air, the causing the solid materials to pass through a revolving furnace in one direction and the air to pass through in the opposite direction; (5) The use of the gases given off by the treatment, in a revolving furnace, of a dried mixture of chloride and oxide of magnesium by highly heated air for the preliminary drying of a fresh mixture of chloride and oxide of magnesium in the same or a separate revolving furnace.—S. G. R.

Improvements in the Production of Basic Lead Carbonate, Chloride, Phosphate, Oxalate, Silicate, Borate, or other Insoluble or Sparingly-soluble Salts of Lead. W. E. B. Benkinsop and F. M. Lyte, London. Eng. Pat. 11,926, August 17, 1888. *Ad.*

THE inventors obtain various insoluble basic salts of lead, such as the carbonate, phosphate, oxalate, &c. by treating some suitable insoluble sort of lead such as the sulphate,

chloride, &c. with the soluble sodium salt of the acid whose lead salt is required. Besides soluble salts for this purpose it is shown that an insoluble salt may be used to obtain the basic carbonate; for example, an insoluble carbonate such as magnesite or dolomite in the presence of water may be employed with equally good results. Warming promotes the reaction.—S. G. R.

Improvements in the Rectification and Concentration of Acetic Acid and in Apparatus therefor. A. Werber, London. Eng. Pat. 12,336, August 24, 1888. *Sd.*

INSTEAD of allowing the rectified acid to flow back into the general bulk of liquid undergoing rectification, as in the usual type of column stills, the inventor allows only the first runnings to do so, and as soon as these attain a sufficient purity (as determined from a small portion withdrawn by a sample cock) the rectified acid is allowed to flow into a separate compartment of the still, from which it distils and is condensed in a suitable condenser. The two compartments may either be two separate vessels or may be one divided into two by a partition. By the use of this apparatus the necessity for interrupting the process in order to draw off the rectified product is obviated; the crude acid mixed with the necessary reagents is run continuously into the first compartment of the still and the rectified product distils continuously from the second compartment.—A. L. S.

Improvements in and Apparatus for the Production and Retention of Chlorine in a Liquid State for Transport or Storage. R. Willeox, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 13,070, September 10, 1888. *Sd.*

THE apparatus is in two forms, suitable either for a discontinuous or continuous method for the liquefaction of chlorine, the plan in both cases being, however, substantially the same. In the former case (Fig. 1) it is U-shaped and formed of two vessels A and B either joined together DD¹ in the lower furnace, so that the material may be easily

Fig. 1.

or else made in one piece and furnished with various stop-cocks, tubes, and secondary pieces of apparatus, the uses of which will be seen from the description. The vessels A and B are filled from *y* to *z* with sulphuric acid (used on account of its small solvent action on chlorine), and from *y* to *x* with petroleum to reduce the effect of the acid on the working part of the apparatus to a minimum. When the cock *g* is opened chlorine is admitted into A and the acid thereby depressed, with the result that the petroleum passes by *d* and *d'* into D. But on closing *g* and opening *f* and

working the force-pump D² the petroleum is driven back into B, and the chlorine in A being strongly compressed is liquefied and passes through the cooler K into the receiver L. The process is then repeated, *gf* being now closed and *g* opened. A is kept at about 50° C. to 80° C. by a jacket containing warm water, or in some other way, in order to still further reduce the solubility of the chlorine in sulphuric acid.

If the process is to be carried on continuously (Fig. 2) then the chlorine is introduced by the small tube *g*² opening

Fig. 2.

into A. This is shut by the valve *i*, which closes as the plunger D² descends and opens as it is raised. Above this is another lift valve *k*. The small tube *P* regulated by the valve *p* serves as a communication between the chamber *m* and the space between the valves *i* and *k*. The remaining details and the mode of working are practically the same as those in the first process already described. The apparatus can be made of cast iron, wrought iron, steel, phosphor, bronze, brass, copper, zinc, or lead. The receiver is best made of iron or steel lined with lead, copper, or brass.—S. G. R.

Improvements in the Manufacture of Soda, Potash and Chlorine. W. P. Thompson. From W. Spilker and C. Loewe, Berlin, Germany. Eng. Pat. 13,306, September 14, 1888. *Sd.*

A SOLUTION of sodium or potassium chloride is electrolysed, a porous diaphragm being used, and the chlorine evolved is collected. A solution of the hydrate of the corresponding alkali metal is also produced, and into this is passed carbon dioxide with the formation of the bicarbonate which can by known methods be converted into the carbonate. The levels of the different liquids are maintained by automatic feed-pipes.—S. G. R.

Improvements in Treating Impure Carbonate of Lime produced in making Alkali, and in Recovering Sulphur from Alkali Waste in order to Utilise it for making Cement, and for other Purposes. R. H. Steedman, Dumbarton. Eng. Pat. 14,026, September 29, 1888. *Ad.*

THE impure carbonates of lime obtained from the sources mentioned in the title are mixed together, heated preferably by steam and thoroughly agitated by mechanical stirrers, or better by blowing air through the mixture. The prejudicial sulphur compounds present are acted upon by the free lime and converted into soluble sulphides, which can be removed by washing. When the mud from Chance's process is alone used, milk of lime must be added. When mud from the causticising process is treated by itself air must be blown through it during the boiling operation.

—S. G. R.

Improvements in the Manufacture of Chlorine, Alkalis and Salts from the Chlorides of Sodium and Potassium. T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 14,199, October 3, 1888. *Ad.*

A SOLUTION of the chloride is electrolysed in a suitable vessel, there being, however, no porous cell or diaphragm employed. Whilst the electric current is passed a stream of gaseous carbon dioxide, preferably under pressure, is forced in and the hypochlorite at first formed is at once decomposed with the formation of the carbonate of the alkali. The carbon dioxide is generated by calcining carbonate of lime,

and the quicklime thus produced can be utilised for converting the alkaline carbonate into the corresponding hydrate.—S. G. R.

Improvements in the Generation of Chlorine, in Forming a Solution therefrom, and in Apparatus therefor. J. Greenwood, London. Eng. Pat. 14,239, October 3, 1888. *Id.*

WITHIN a large battery jar is placed a series of carbon rods carried on a ring of suitable material, and the whole connected to the negative terminal of an electric generator. A porous cell is placed inside the battery jar and within this again is placed another series of carbon electrodes connected to the positive terminal. Through the outer jar, by means of pipes, a concentrated solution of common salt is passed at any required rate, and through the porous cell a stream of water which, on electrolysis the salt solution, absorbs the chlorine evolved at this terminal, and hence a chlorine solution of such strength as may be required can be readily obtained. A sketch of the required apparatus is given.—S. G. R.

Improvements in the Manufacture of Acetic Acid. M. Cannon, London. Eng. Pat. 11,333, October 5, 1888. *Id.*

THE object of this invention is the preparation of acetic acid, free from tarry matter, from crude pyroligneous acid or its calcium salt. This is achieved by oxidising the tarry matter by nascent oxygen liberated by the action of sulphuric or hydrochloric acid on one of the higher oxidised compounds of manganese.

When the crude calcium salt is the raw material it is first of all distilled with sulphuric acid to obtain the free acid. The impure acid is digested for 12–18 hours with 3 per cent. of one of the following: Manganese dioxide, sodium manganate or other manganate, potassium permanganate or other permanganate. These are added to the cold acid, sufficient sulphuric acid to decompose them is then added, and the temperature raised to 140° F. and kept at that temperature until all effervescence has ceased. The liquid is then distilled, the vapour being condensed in a silver or tin condenser. The distillate, with the exception of the first tenth and the last twentieth, which are re-treated with the next batch of crude acid, is colourless, free from unpleasant taste or smell, and may be used for any of the purposes for which pure acetic acid is required, such as the manufacture of white lead, white acetate of lead, emerald green or other colours, sodium acetate and vinegar.

If an acid of exceptional purity be required the operations may be repeated, using 1 per cent. of the oxidising material. The manganese of the residue in the retort may be re-oxidised by any of the usual methods.—A. L. S.

Improvements in or relating to Manipulating and Washing, Filtering, or otherwise Treating Lime Mud, Black Ash or other Materials in Bulk during the Course of Manufacture, and in Apparatus therefor. G. H. Bolton and T. A. Bullough, Widnes. Eng. Pat. 14,563, October 10, 1888. *Id.*

IN many processes the materials at one time or another have to be conveyed to a filtering press, there filtered and the residue then dug out and conveyed to some other locality in the works. It is proposed to make the filter press itself in the form of a waggon or other equivalent travelling vessel. It can then be readily placed below a converter, causticiser, &c., and the sludge emptied directly into it, and this can then be at once exhausted. In many cases the filtering press can be further fitted with the required apparatus, so that the next reaction or process can be performed within it, thereby obviating any further transference of material altogether.—S. G. R.

Improved Process for the Manufacture of the Hydrates of the Alkalis of the Alkaline Earths, and of their Carbonates, which Process is also applicable to the Dissociation of Alloyed Metals. F. T. Romiquères, Paris, France. Eng. Pat. 11,977, October 18, 1888. *Id.*

TWO boilers are taken, connexion between which can be made at pleasure, and each is about three parts filled with finely divided lead. A solution of concentrated caustic soda containing a little sodium sulphate is run into one of them until the lead is just covered and heat is applied, air being subsequently blown in until a pressure of from 4 to 5 atmospheres is obtained. The solution is then forced into the second boiler, where a similar process is carried on, and this is repeated until all the lead is oxidised and dissolved as plumbite of soda (Na_2PbO_2). On treatment of the solution thus obtained with sodium chloride, chloride of lead is precipitated with the formation of caustic soda in the proportion of two equivalents for each equivalent used in the formation of the plumbite. If carbon dioxide gas be blown in with the simultaneous addition of sodium chloride, then the carbonate of soda is produced. The hydrates of other alkalis can be similarly prepared. Besides lead, other metals such as zinc, arsenic, antimony, tin, can all be treated in this manner, and hence alloys may be separated into their constituents, each being subsequently thrown down from solution in due order and by suitable precipitants.—S. G. R.

Improvements in or connected with the Manufacture of Chlorine. H. W. Deacon and F. Hurter, Widnes. Eng. Pat. 15,063, October 19, 1888. *Id.*

DRY hydrochloric acid gas mixed with the requisite amount of dry air is obtained by adding salt in the required amount to sulphuric acid. Air is blown through the liquid mass by means of a pipe terminating in a rose and dipping below the surface. The air is thus both dried and the agitation caused by its passage through the liquid bisulphate of soda helps in the more complete decomposition of the salt. The gases when thus dried are found to be more suitable for treatment in Deacon's chlorine process than when in a moist condition.—S. G. R.

Improvements in Obtaining Carbonic Acid Gas from Mixtures with other Gases, Obtaining and Utilising the Residual Gases or otherwise, and in the Production of Carbonates of Ammonia. C. F. Claus, London. Eng. Pat. 15,173, October 22, 1888. *Id.*

THE gaseous mixture is, if necessary, first of all cooled and passed through special scrubbers to remove any sooty or tarry matters. The gases then traverse a series of scrubbers from the top of one to the bottom of the next in the usual manner. The last scrubber is fed with fresh ammoniacal liquors which are then pumped to the top of the next scrubber and so on; hence in the first scrubber the fresh gases meet a solution containing a little ammonia and much sesquicarbonate, whilst in the last the ammonia is very largely in excess, the carbonic acid gas having been already almost entirely absorbed. If the residual escaping gases are of value they pass to a gasholder. The sesquicarbonate solution is now pumped to the top of a scrubber termed the condensing tower in connexion with the heating apparatus, and thence into this latter. This consists of a series of shallow closed tanks one above the other, and all enclosed in an air-tight casing or heating chamber. Steam is then injected when seven-eighths of the carbonic acid gas, accompanied by a little ammonia, is driven off and passes through the condensing tower just mentioned to another washing scrubber fed with water, where the last traces of ammonia are removed. These washings pass to the top of the condensing tower, and the pure carbonic acid gas to a gasholder. When the sesquicarbonate of ammonia is required as an essential by-product, it is not run, after reaching the bottom of the condensing tower, into the heating apparatus, but into special receptacles, and used in the ammonia-soda process. In this case a higher temperature in the heating apparatus is also maintained in order to leave less ammonia in the liquors running from it.—S. G. R.

An Improved Process of Manufacturing Acetate or Pyro-lignite of Iron or Iron Liquor. P. McLaren, Falkirk. Eng. Pat. 15,293, October 24, 1888. 6d.

A TUN or cistern of sufficient size is nearly filled with a mixture of sawdust and finely-divided iron, and upon this is run the acid. After standing for a few hours the acid is found to be saturated and is then run off by a pipe placed in the bottom of the vessel. A fresh charge of the acid preferably warmed is then introduced. It is claimed that in this way a much purer product is obtained, that cast-iron borings, or what is called in commerce "iron rust," can be employed, that the acid is saturated in a much shorter time, and that there is no loss of iron inasmuch as there is no preliminary burning of the iron to free it from the tarry matter usually adhering to it, this being retained by the sawdust. The sawdust when too impure can be dried and burned in the furnaces of the manufactory.—S. G. R.

Improvements in Apparatus for Incinerating Spent or Used Alkaline Lyes or other Waste Products or Precipitates containing Carbonaceous Matter. T. McDougal and J. Jarline, Penicenick. Eng. Pat. 15,675, October 31, 1888. 8d.

THE apparatus herein referred to consists essentially of a furnace made up of three main parts, these being placed the one above the other. At the top is a large pan in which the lye is partially concentrated by waste heat from below. Under this are two brickwork vessels, deeper in the centre than at the sides, running the whole length of the furnace. These rest on the crown of the arch of what is practically a reverberatory furnace which is furnished with a fire at each end, and with its hearth divided into two portions by a ridge raised above the bottom and running the whole length of the bed. The working of the furnace is as follows:—After the lye has undergone a partial concentration in the upper pan it is run by suitable channels on to the shelving sides of the tanks below, over whose heated surfaces it passes to the lower central portions, the tanks being thus gradually filled. Here it is further concentrated, and then by apertures passing through the crown of the arch it reaches the hearths below, where the final incineration takes place. By a suitable arrangement of flues the heated gases from the furnaces can be caused to travel in any required direction.—S. G. R.

The Treatment of Waste Liquors from Galvanising Works or other Liquids containing Chloride of Iron or Chloride of Iron and Hydrochloric Acid, and for extracting therefrom Oxide of Iron and Hydrochloric Acid. T. Turner, Birmingham. Eng. Pat. 16,166, November 8, 1888. 4d.

THE liquors having undergone, if necessary, a preliminary concentration, are run into suitable vessels kept at a temperature considerably above the boiling point of the liquid, but below a red heat. Hydrochloric acid is driven off with formation of basic chlorides of iron. Air and steam are then introduced, with the complete conversion of the chloride into the oxide and the liberation of the residual hydrochloric acid. The hydrochloric acid gas is passed through condensing towers or other convenient apparatus.—S. G. R.

Improvements in Vessels used for Boiling and Evaporating Acids or Strong Alkalis. W. Townsend, Ravensthorpe. Eng. Pat. 16,523, November 14, 1888. 4d.

THE inventor places within the metal retorts either a fireclay or earthenware glazed vessel set in cement, the apparatus being thus more durable and not acted upon by the liquors to be concentrated.—S. G. R.

Improvements in the Manufacture of Common Salt and in the Construction of Appliances for effecting the same. A. Collingridge, London. From V. Cornet and A. Jones, Paris, France. Eng. Pat. 3338, February 25, 1889. 8d.

THE brine travels from an overhead reservoir through a filtering press made in sections bolted to one another. It then passes to an evaporating chamber, divided into an upper and smaller and a lower and larger division by a horizontal partition, where it is heated and concentrated by a fire placed beneath. The steam which is formed is taken by a suitable arrangement of pipes through a series of either iron or stout porcelain retorts, which are charged with finely-divided iron scrap or turnings, and placed in the furnace already mentioned, and which thus subserves two purposes. The inflammable gas thus produced can either be stored until required for use or it is burnt in the upper division of the evaporating chamber in ordinary atmospheric burners, the heat being concentrated on the dividing diaphragm in the evaporating chamber, and thus aiding in the more rapid evaporation of the brine.—S. G. R.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

Manufacture of Bottles by Machinery. H. M. Ashley. (A Paper read before the Mechanical Science Section of the Brit. Assoc., Newcastle Meeting, 1889.)

THE new system of manufacture is based on the fact that glass, generally a very slow conductor of heat, becomes, under certain conditions, a very rapid conductor. By varying the temperature glass can within five minutes be rendered fluid, plastic, elastic, or brittle. It was during the transition of the glass from the solid to the molten state that the plastic condition is reached. In the process of the author no joints or welds are required, and the operations necessary may be briefly described as casting, punching, and blowing. A dummy bottle is first cast in an inverted position in what are known as "parison and ring" moulds; then, whilst semi-fluid, a hole is punched inwards in the neck, the piece removed remaining inside and serving to form part of the bottom. The bottle is finally completed by being blown out with compressed air in the bottle-mould. The air pressure was about 10 lb. per square inch. The apparatus is arranged on a rotating frame, by means of which the bottle in its various stages of development is passed on from one operator to another. It was stated that the glass treated by this process is very strong, and that a better finished bottle could be turned out by it than by the old process.

The Technology of Glass. Dingl. Polyt. J. 273, 129—131.

O. SCHOTT describes experiments which he has made with a view to improving the quality of glass used for optical and scientific purposes. He tried the effects of the addition to the glass of a large number of materials such as boric and phosphoric acids, cadmium, zinc, erbium, cerium, didymium, thallium, and other metals. Fletcher's ovens were used in the experiments. In attempting to reduce chromatic aberration it was found that boric acid caused a contraction in the blue portion of the spectrum and an expansion in the red, whilst fluorine, sodium, and potassium acted in the opposite way, the other substances tried producing no differences. Boric acid can consequently be advantageously added to flint glass, which shows excessive aberration in the blue. The percentage of potassium which can be introduced into crown glass being rather limited, fluorine, which is easily added to phosphate glass, should also be added. Phosphoric acid, combined with certain metallic oxides, gives glasses of low dispersion and high refraction. Such glasses, combined with boric acid flint glass, form excellent objective glasses for telescopes. Alkalis must be added in small amount only to

boric and phosphoric acid glasses, or otherwise the polish of the glass is quickly injured by atmospheric influences. Hygroscopic glass is rendered serviceable by the addition of fairly large proportions of alumina, zinc oxide, &c. With phosphate glass, magnesia, alumina, and potash produce the least dispersion. Baryta and phosphoric acid yield crown glass with little dispersion and an index of refraction of 1.55 to 1.59.—E. B.

PATENTS.

Improvements in the Utilisation of Waste and other Glass. H. A. Pavely, Richmond. Eng. Pat. 12,450, August 29, 1888. *Ad.*

WASTE and other glass is melted and poured into suitable moulds for the manufacture of bricks, tiles, drain pipes, and the like.—E. G. C.

New or Improved Machinery for the Manufacture of Seggars or Saggars, Crucibles, Melting Pots, Pipes, and other Hollow and Tubular Articles from Clay or other Plastic Material. J. Hamblet, West Bromwich. Eng. Pat. 14,644, October 11, 1888. *1s. 1d.*

FOR details of this invention the specification and drawings must be consulted.—E. G. C.

Improvements in or relating to Painting or Printing upon Earthenware. W. H. Turner, Tunstall. Eng. Pat. 18,577, December 19, 1888. *Ad.*

THE inventor produces the design upon the plate or roll by etching with acid in the well-known manner, but instead of completing the process at one or two operations, he prefers to make several operations of it, by this means "obtaining differences and fineness of shade hitherto unobserved."

—E. G. C.

Improvements in the Manufacture of Porous Earthenware. H. J. Allison, London. From C. C. Gilman, Eldora, Iowa, U.S.A. Eng. Pat. 9645, June 11, 1889. *Ad.*

FIBRES of asbestos wool are introduced into the plastic composition and thoroughly incorporated with it.—E. G. C.

An Improved Compound suitable for the Manufacture of various Articles by Moulding. H. H. Lake, London. From C. T. Lee, Boston, U.S.A. Eng. Pat. 9927, June 17, 1889. *Ad.*

SIXTY-FIVE parts by weight of mica in pieces varying in size up to "one-eighth or one-quarter of an inch" are incorporated with 35 parts of shellac by the aid of heat, worked into sheets and afterwards re-softened for moulding, or moulded direct into any desired shape. The laminated character of the mica enhances the strength of the product.

—B. B.

Improvements in the Manufacture of Translucent Enamel, and in the Application of the same in Relief for the Decoration of Glass, Metal, or any Ceramic Ware. W. Lutwyche, London. Eng. Pat. 10,322, June 25, 1889. *Ad.*

THE following materials are used in the production of this translucent enamel:—minium, boric acid, oxide of zinc, stannic acid, sand, soda, feldspar, fluor spar, carbonate of potassium, carbonate of calcium, borax, and sodium nitrate. The colouring matters are manganese dioxide, purple of Cassius, ferric oxide, lead chromate, cobalt oxide, cuprous oxide and cupric oxide.—E. G. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Notes on Portland Cement. Zeits. f. angew. Chem. 1889, 366—371 and 384.

Schumann has shown (Zeits. f. angew. Chem. 1881, 523) that all cements and building stones expand when saturated with water, and contract on drying. Recent experiments of his fix the mean expansion for prisms of one part of Portland cement, and three of normal sand 10 cm. in length, at 0.0088 mm. for one week, and 0.002 mm. for one to four weeks, the test pieces being kept under water. The contraction in the dry state is of greater importance; similar prisms kept under water for one week and then exposed for three weeks to the air, gave an average contraction of 0.0417 mm.

R. Dyckerhoff has investigated the influence of magnesia on Portland cement. He finds that up to 3 per cent. no evil effect can be traced to it, but larger proportions cause the cement to be of an exceedingly treacherous character, as its tendency to retrograde in strength and to expand is only manifest after the lapse of many weeks, and thus escapes detection by the standard tests.

The test used for detecting a tendency to expand is called the "firing" test ("Darrprobe"), and is executed as follows:—The cement is gauged neat with enough water to make it of normal consistency, and two pats 10 × 1 cm. made of it on glass or metal plates, and placed in a damp box in order to protect it from sunshine or draughts, and thus avoid the formation of cracks due to shrinkage. At the end of 24 hours the pats are transferred to an air-bath, the temperature of which is gradually raised to 120° C., and kept there for two or three hours after the last visible evolution of steam has ceased. Any crumbling, or the formation of cracks starting at the edge of the pat, and disposed somewhat radially, condemns the cement for use in work exposed to the air. Care must be taken to distinguish the cracks above-mentioned from cracks caused by shrinkage due to too rapid drying; these latter start from the centre, and occur concentrically or assume the form of a capillary network.

Cements which are not burnt to the sintering point, e.g., Roman cement, are less liable to injury from the presence of much magnesia. (Cements made from magnesia and magnesium chloride, harden in the air, but soften when exposed to moisture; marble-like table-tops made by F. A. Schmidt of Dresden failed from the same cause, and their manufacture had to be given up.)

Schott long endeavoured to make a cement of purely basic materials by burning together magnesite and waste marble, founding his hopes on the fact that intimately mixed calcium and magnesium carbonates yield on ignition a slightly sintered mass which, when finely powdered, sets under water, but without success.

R. Dyckerhoff finds that Portland cement mortars, after free exposure to the disintegrating influence of the atmosphere for 10 years, show a distinctly increased strength in compression.

In the case of the cement from "Stephans Dom" in Vienna (which appears to have failed), analysis showed that it had been used without the addition of sand, and revealed no cause for its destruction; various observers advance different hypotheses, such as assigning the failure to the action of water penetrating into the crevices due to the shrinkage of the cement, which shrinkage would have been avoided by the use of sand, also to the inferior character of the stone itself, while Schott dwells on the fact that the cement was of English make.

Schiffner enumerates three heads under which the influences governing the hardening of Portland cement may be grouped. (i.) The nature and character of the normal sand. (ii.) The influence of foreign matters, such as acid liquids, vegetable oils, liquors containing tannin, sour beer, and such like, that may come in contact with it, owing to the use to which structures built with it may be put. (iii.) The careless treatment of it while building, e.g., delay in using it after mixing, the use of too much or too little

water, and so forth. He has instituted a series of experiments, showing the result of different treatments of cement after gauging. (i.) Cement put, immediately after gauging, in a closed box for 24 hours, then kept 27 days under water, and finally exposed to the extremely dry air of the laboratory, showed no signs of expansion, was of satisfactory hardness, and had no tendency to retrograde in strength; it contained 10—11 per cent. of combined water and 1·15 of carbonic anhydride. (ii.) Cement treated in the same way, save that it was kept only three days under water, was somewhat inferior in hardness to that mentioned under (i.), but showed no proneness to expansion or distortion: it contained 6—7 per cent. of combined water and 15·25 per cent. of carbonic anhydride. (iii.) Cement exposed at once to dry air was all more or less friable; its precise condition was governed by several causes, such as the time of year, thickness of the test-pat, fineness, rate of setting; it contained less than 4 per cent. of combined water, and 7—8 per cent. of carbonic anhydride.

The reason of this is simple: parts not exposed to water or very damp air for a sufficient time, fail to obtain enough water for their complete hydration: this was strikingly shown by transferring some of the pats—so friable that they could be moved only with difficulty—to water for four weeks, at the end of which time they had become fairly hard and permanent in air.

Böhme proposes that the normal consistency of a cement be determined by means of a standard needle having a circular end 1 cm. in diameter and loaded with 300 grms. If this come to rest 6 mm. from the surface of a glass plate on which is the cement to be tested, confined by a ring 8 × 1 cm., the consistency of that cement is normal.

Tomčič has ascertained the influence of air and other gases on the strength of Portland cement. Dry carbonic anhydride, and, in a less degree, dry air, increase the strength in tension and compression appreciably, while moist air, dry sulphuretted hydrogen, and the addition of 0·25 to 1·00 per cent. of calcium sulphide considerably lower it.—B. B.

PATENTS.

Manufacturing Artificial Stone. E. de Pass, London.

From R. H. Stone, Brighton, Victoria. Eng. Pat. 4927, Nov. 10, 1881. (Second Edition.) 6d.

This inventor uses the following materials and proportions:—Sand, 70—80 per cent.; amorphous silica or silicates, 10 per cent.; slaked lime, 10 per cent.; water, 10 per cent., by measure respectively.—E. G. C.

Improvements in the Manufacture of Artificial Stone and Concrete Blocks. J. W. Ransome, Stoke Newington.

Eng. Pat. 14,286, October 4, 1888. 4d.

The usual method is to mix the materials (say Portland cement and sand), with water, and to place the mixture in a mould. According to the present invention the dry materials are placed in a mould and exposed to pressure, and while in this state water is introduced, preferably from beneath.—E. J. B.

Improvements in the Manufacture of Cement. C. J.

Widmark, Örebro, Sweden. Eng. Pat. 964, January 18, 1889. 4d.

The inventor claims the manufacture of cement by submitting lime, previously burned to the ordinary degree, or such other ingredients as may be used, "to a further burning under a high degree of heat, and then pulverising it or them."—E. G. C.

An Improved Vitreous Material for Paving and other Purposes. J. Rust, London. Eng. Pat. 13,211, July 13,

1889. 4d.

The ingredients are:—Sand, soda ash, native barium carbonate, China clay, phosphate of lime, and sodium nitrate.

—E. G. C.

X.—METALLURGY.

The Influence of Chemistry upon the Iron and Steel Industry in Recent Years. Sir Lowthian Bell, Bart. (Presidential Address to the Chemical Section of the British Association, Newcastle-on-Tyne, 1889.)

It has occasionally been the practice of former occupants of this chair to devote a considerable portion of the presidential address to the more recent discoveries in chemical science. This branch of learning advances now with such rapid strides and covers so wide a field that no one who has not made it the business of his life can hope to discharge this duty with even a moderate share of success.

My immediate predecessor, indeed, discouraged any further attempts in this direction on the ground of the impossibility of doing it justice within the limits of a short discourse, and his remarks were consequently directed to the best methods of teaching the science with which Section B is more directly concerned. I propose this morning to add my testimony to the importance of Dr. Tilden's recommendation by comparing the rate of progress of one of our great national industries as it has been advanced with and without the aid which chemistry is capable of affording. For this purpose I have selected the metallurgy of iron, not only from my greater familiarity with its details, but because, in my judgment, it affords a suitable example for the object I have in view.

It is needless to insist on the disadvantage attending the application of a science to practical work, without a fair knowledge of the principles which regulate its action. At the same time it would be unfair to those who were engaged in the manufacture of iron during the first half of the present century, to deny the value of the services which they rendered to their art, without having given much thought to the laws of nature upon which their processes depended. The work so performed sufficed, nevertheless, to place the world in possession of the metal in such abundance and at so low a cost that no engineering works were delayed on account of the high price or absence of the required quality in the produce of our ironworks during the period in question. On the other hand it is not to be denied that since the ironmasters have allied themselves with the chemist they have made more progress in thirty years than their predecessors did in three centuries.

No one unacquainted with the archaeology of the iron trade could suppose that the colossal furnaces now pouring forth their streams of molten metal, followed by the rapid action of the Bessemer converter, were the modern representatives of the iron-making appliances of former days. Out of these last, in a low hearth not larger than a domestic fireplace, often dependent on the wind for their blast, a few pounds of ore were, at a considerable cost for labour, fuel, and waste of metal, converted into malleable iron. By means of a modern furnace, in an hour and a half a 10 ton converter can be filled with liquid cast iron, which in 20 minutes may be run into ingots cheaper, stronger, and more malleable than the best wrought iron of our ancestors, or indeed of our own manufacture.

How out of the small fire of the ancient ironworks, the German Stück-Ofen was evolved is a matter of conjecture. In both, owing to the conditions under which the fuel was burnt, carbon dioxide was largely the product of its combustion. The oxidising property of this gas was in each the cause of the waste of metal just spoken of. Probably, and for other reasons than avoiding this loss of iron, attempts were made to increase the dimensions of the Stück-Ofen. If this addition were one of limited extent, the smelter would find, to his cost, that a substance was obtained which no longer possessed the malleable property of that obtained from the lesser furnace. This change would be due to the absorption of carbon, but not in sufficient quantity to constitute that valuable form of the metal known as cast iron. With a material, useless for the smith and incapable from its difficult fusibility of being run into moulds, we can understand the delay which took place in the introduction of the blast furnace which, about the middle of the 16th century, gave to cast iron a recognised and valuable position in the arts.

In those days there was no very exact science to appeal to, for 250 years after the "high furnace" of the Germans and French had been set to work, Fourcroy, in his "General System of Chemical Knowledge and its Application to the Phenomena of Science and Art," arrived at the conclusion that cast metal was erroneously supposed to be a mixture of slag and iron, or a compound of arsenic or manganese and iron. This was written in 1804 in a work of 5,000 pages, when he lent to the opinion that Monge and Berthollet were more correct in considering the product of the blast furnace as consisting of iron, oxygen, and carbon.

When the malleable iron-maker had placed in his hands a material containing, as the pig did, more than 90 per cent. of metal, he found it greatly to his advantage to avoid having to deal with all the earthy matter contained in the ores, for it was the presence of silica and alumina which helped to add to the waste incurred in the old hearths. The object sought for in treating ore in the old Catalan fires, as they were called, was one of a reducing or deoxidising character, whereas the reverse of this was required when ore was replaced by pig iron. In the first case, oxygen had to be removed from the oxide of iron, in the latter oxygen had to be united with the metalloids found in the pig. These were distinctions unknown in the days we are considering, and therefore did not trouble the minds of the ironmasters. In both cases there was a large quantity of oxide of iron present, and when pig iron was handed over to the Catalan furnaceman, it was the oxide of iron so generated which performed the desired duty, and thus this simple mode of procuring malleable iron remained undisturbed for upwards of 200 years.

The discovery which led to the discontinuance of the low blast furnace as a means of procuring iron in its malleable form was that of puddling made by Cort in 1784. In point of fact Cort's process was merely doing in a reverberatory furnace that which was previously effected by means of compressed air. In an economic point of view, however, the difference is great, and its consequences were of immense importance, for to the puddling furnace we were first indebted for an ample supply of cheap iron by which, in a variety of well-known ways, the interests of the human race have been so largely promoted. As an indication of the indifference of those formerly engaged in industrial pursuits to the scientific aspect of their calling, may be mentioned the fact that puddling had been largely followed for upwards of half a century before it occurred to any one to examine the chemistry of the process.

Down to the beginning of the 17th century the only fuel used in the blast furnace, and, indeed, in the manufacture of iron generally, was charcoal. In 1620 Dudley made several attempts to substitute mineral coal in his smelting works for vegetable fuel, which, by the exhaustion of timber, had become very expensive. He failed in this, and in consequence the British iron trade gradually fell, until the entire output was not equal to the production of one modern blast furnace. This happened in 1740, when Darby, by treating pit coal in the same fashion as the charcoal burners had done with wood, i.e., by charring it, restored vitality to an expiring industry. It is true that the restoration must have been of a languid character, for in half a century afterwards it is said the weekly produce of a furnace did not exceed 15 or 16 tons.

Various changes were introduced into the manufacture of iron in the first quarter of the present century, but these were rather of a mechanical than of a chemical nature. They chiefly owed their origin to the lessons taught by the chemist Black to James Watt, who profited by them in the application of steam as a motive power. This brings us to the year 1828, a year which will always be distinguished in the annals of the iron trade, by the discovery of Neilson of the value of heated air in smelting the ores of this metal. I never heard it maintained that this inventor had any pretensions to be considered a man of science. Had it been otherwise, the knowledge of the virtues of the hot blast might have been indefinitely postponed, and this opinion is founded on the fact that for many a long year no satisfactory explanation was given why heat, obtained by burning coal, in the hot air apparatus, was capable of saving three or four times its weight in the fuel consumed in the furnace itself.

I propose, with your permission, to consider this subject with more attention than I shall devote to other portions of this address, and I am led to do this, not only because it is one of some scientific interest, but because its study seems to afford a solution to some questions in respect to which great differences of opinion prevailed among those whose daily work led them to pay much attention to their details. These questions have all a reference to the quantity of fuel consumed in smelting the ore, as this may be affected by the temperature of the blast and the dimensions of the furnaces employed for this purpose.

As is well understood, the heat excited in an iron furnace may be classified under three heads:—

First, that derived from the combustion of the coke at the point where the blast enters the furnace, the ultimate product being carbonic oxide.

Second, the conversion of a portion of this carbonic oxide into carbon dioxide.

Third, the heat carried into the furnace by the blast.

For the better illustration of the relations which the heat derived from these sources bear to one another, a table (No. I.) has been prepared in which the quantities of each are given in centigrade calories, and reckoned upon 20 units of iron to correspond with English weights. The information upon which the calculations are based is derived from actual observation gathered from furnaces of different sizes and fed with air at different temperatures.

A second table contains statements showing the manner in which the heat so generated is appropriated in the various divisions of the duty the furnaces had to perform, and for facility of comparison, alongside the quantities of heat so required, their equivalents in the coke used have been added.

In the table No. II. the appropriation of the heat is separated into *Constants* and *Variables*. The first consists of items where the quantity of heat required in making a particular quality of iron is only liable to alterations of trifling amount. On the other hand, the variables exhibit in A and B differences so considerable that work which in the furnace blown with cold air absorbed 73,388 calories per 20 cwt. of pig iron was done with 58,645 calories by merely raising the blast to 485°.

TABLE I.

—	A.	—	—	—
Height of furnace in feet.....	48	48	80	80
Calories per unit of coke burnt to CO.....	2,078	2,028	2,018	2,045
Calories from portion of this CO burnt to CO ₂	560	1,059	1,636	1,463
Total calories from coke	2,638	3,087	3,654	3,508
Calories in blast	—	508	534	732
Total heat per unit of coke.....	2,638	3,595	4,188	4,240
Temperature of blast C	0°	485°	485°	695°
Cwt. blast per ton of metal.....	228	128	163	94
Cwt. escaping gases per ton of metal.....	285	170	138	126
Cwt. slag per ton of metal	31	31	29	28

The cause of this great variation in the amount of heat required for a given weight of pig iron, produced under different circumstances as to temperature of blast and size of furnace, depends on changes in the actual amount of work to be performed. How this variation arises will be best seen in the description of the four examples set forth in the two tables.

TABLE II.—SHOWING THE APPROPRIATION OF HEAT AND ITS EQUIVALENT PER TON OF IRON IN CWT. OF COKE.

Appropriation of Heat per 20 of Pig Iron.	A—Blast 6° C.		B—Blast 485° C.		C—Blast 485° C.		D—Blast 695° C.

Cwt. of coke for 20 of pig iron	45'	..	28'92	..	22'32	..	21'24

Beginning with A, which is a furnace 48 ft. in height, blown with cold air and consuming 45 cwt. of coke and 18 cwt. of limestone per ton of metal, the volume of gas produced may be taken at 14,460 cubic yards at ordinary temperatures and pressures. At the temperature at which it escapes we may assume the volumes per ton of iron to be about 36,000 cubic yards, passing out of the furnace at the rate of 675 cubic feet per minute.

In comparing the consumption of coal formerly burnt in the hot-air stoves with the saving of coke in the furnace, account must be taken of the different conditions of the combustion. In Table I., owing to the small quantity of carbon dioxide formed, the heat evolved is only 2,638 calories per unit of coke, whereas each unit of the coal consumed in heating the air afforded three times this quantity of heat. Doubtless there was a great loss in the operation of heating the air, for it would not appear that much above one-fourth of the theoretical quantity of heat capable of being generated by the coal reached the furnace through the tuyeres.

We have now to consider the nature of the change which is effected in a furnace where, for every 2,638 calories generated by the combustion of the coke, 508 calories are carried in by the blast. It will be readily understood that, with the velocity at which the gases are passing out of the cold-blast furnace, they have but little time to impart their heat to the incoming solids, or to have the carbonic oxide they contain converted into carbon dioxide. The withdrawal of so much coke, and its place taken by heat contained in the blast, means that the 14,460 cubic yards of escaping gases are reduced to about 12,120 cubic yards. The effect of this is not only to alter the speed at which the gases are passing through the materials, but to alter the relation in point of quantity which the ironstone present in the furnace bears to the coke, so that in point of fact a larger space is occupied by the ore than was before, and a lesser one by the fuel. We have thus the carbonic oxide passing more slowly over the oxide of iron at the same time

that there is a greater quantity of the oxide exposed to the influence of the reducing gas. To illustrate how this operates, a table has been prepared showing how each 1,000 cubic feet of furnace space is occupied in the four cases we are considering:—

	A.	B.	C.	D.
	48 ft. Cold Blast.	48 ft. Hot Blast.	80 ft. Hot Blast.	80 ft. Hot Blast.
Coke.....	Cubic Feet. 736	Cubic Feet. 686	Cubic Feet. 590	Cubic Feet. 590
Limestone	63	75	86	77
Ironstone	201	239	324	333
Total.....	1,000	1,000	1,000	1,000

The immediate effect of the introduction of the hot blast is to alter the spaces filled by the three minerals from those given in Column A. to coke 686, limestone 75, and ore 239 cubic feet. This is followed by a twofold advantage. Volume for volume, ore and limestone possess double the heat-intercepting power of coke, and there is 19 per cent. more ore ready to oxidise the carbonic oxide passing over it at a reduced speed of 16 per cent. than there was when using cold air. The increased efficiency of the coke, due to a more perfect cooling of the gases and higher oxidation of the carbonic oxide, permits its further suppression until the relative spaces filled by the materials are those shown under Column B. These advantages would not of themselves suffice to save 16 cwt. of coke or thereabouts out of 45 cwt., but the reduction in the coke consumed is followed by a diminution in the quantity of air used and in the weight

of gases and slag produced. A reference to the appropriation of heat classified under the head of "Variables" will show in consequence diminution from 73,338 to 54,643 calories.

It may be asked whether this prolonged exposure of the ore to the reducing gases could not be secured by driving the furnace at a slower speed. There is, however, a point which may be regarded as one of equilibrium, at which the quantity of cold materials charged at the top just suffices to reduce the temperature of the escaping gases, as far as is possible consistent with the dimensions of the furnace. If the volume of blast entering at the tuyères is lowered one-half it would mean that the materials would be exposed for twice the time to the hot gases that they were previous to the alteration in the rate of driving. The elevation in the temperature of the coke would enable its carbon to act on the carbon dioxide, so that there would ensue as great a loss under the second head of heat evolution in Table I. as there is gained by a more perfect interception of the heat contained in the gases.

There is, however, another way of securing this prolonged exposure of the ore to the action of the reducing gas without incurring the inconvenience just referred to, viz., by increasing the dimensions of the furnace blown with cold air. When this was done by raising the height from 48 to 71 feet it was found that the duty performed by the coke, apart from the heat contained in the blast, was just about the same as that in the hot-blast furnace.

With regard to the position of equilibrium above referred to, it is worthy of remark that, while this was reached when a furnace of 48 feet ran 100 tons per week when driven with cold air, it was not arrived at in one of similar dimensions using heated air until the make was increased to about 220 tons.

When we proceed to examine the composition and weight of the gases given off by a 48-foot furnace blown with air at 485°C ., it will be found that about 20 per cent. of the carbon as dioxide has disappeared, due no doubt to the still excessive temperature of the upper zone and too rapid a current of the reducing agent. An obvious way to remedy this evil would be by an addition to the capacity of the furnaces. This was done by raising them to a height of 80 feet, with a cubical space three or four times greater than those of 48 feet. In such a furnace almost the full theoretical quantity of carbon as dioxide has been obtained, but, while the larger furnace held three or four times more ore, &c., than the smaller, the production was only about double that of the lesser. On referring to Table II., it will be seen that a further economy of 6.6 cwt. of coke has been effected in furnace C. as compared with B., due solely to an enlargement of space, for the temperature of the blast was exactly the same in both. This improvement, it will also be perceived, is due to an extension of those causes which acted so beneficially when hot air was applied to B.

If 6.6 cwt. of carbon or thereabouts be the full quantity per ton of iron which can be found in the gases as dioxide, and if, in a furnace working under the conditions of C., it requires 22.32 of coke to furnish this carbon, and that in the carbonic oxide, it is clear we cannot withdraw any coke without disturbing the position of equilibrium supposed to have been established in the case of the furnace in question. Suppose that into such a furnace, the blast, instead of 485° , is admitted at 695° as happened under Column D. The additional heat, 732 calories, instead of 534 as in C., will make itself felt throughout the entire height of the furnace, including, of course, the upper zone. Immediately this happens, some of the carbon dioxide generated by the reduction of the ore attacks the coke and escapes as carbonic oxide. If Table I. is examined, it will be seen that almost the whole of the additional heat carried into the furnace D., as compared with C., has been absorbed by the disappearance of carbon dioxide, so that the net power of the coke unit in both cases is practically the same. Nevertheless, it will be remarked that there is still a small saving of coke due to a reduced amount of blast, escaping gases, &c.

From what has preceded, it has been concluded that a furnace of 80 ft. affords sufficient opportunity for the gases being as fully saturated with oxygen as the nature of the

process of deoxidising the ore will permit. The sensible heat in the escaping gases, however, still represents a considerable loss, reduced, as it has been, from 29,482 to 11,013 calories.

According to estimate it was believed that the reduction of oxide of iron ought to be attended by an increase of temperature—in other words the conversion of carbonic oxide into carbonic dioxide produced more heat than that absorbed by splitting up oxide of iron into its constituent parts. The estimated difference not being a large one, an experiment was made by substituting in the furnace inert substances having about the same specific heat as the ore. The results confirmed the correctness of the calculation—the temperature of the escaping gases fell, and rose to their normal point when the use of ore was recommenced. A more expensive experiment was subsequently made in the same direction by building, at Ferryhill, a pair of furnaces having a height of 103 feet, without any substantial benefit being derived from the large additional expenditure incurred.

It was Scheerer, I think, who first divided the blast furnace into zones. The first division, beginning at the top and extending 12 feet downwards, was designated the preheating zone; the following 18 feet downwards was distinguished as the reducing zone; the next 8 feet the carburising zone, followed by 4 feet which constituted the zone of fusion. The lowest of all, having a depth of about 6 feet, was named the zone of combustion. The author of this mapping out, as it were, of the interior of the furnace does not wish to be understood as confining its various functions within the respective spaces assigned to them; on the contrary, he admits the existence of considerable variations of position. My own observations, however, have led me to conclusions varying considerably from those adopted by Scheerer.

The fundamental cause of these differences seems to depend on the temperature considered as being required for a commencement of the reduction of the ore. By Scheerer, the reducing zone is considered to require a temperature of $1,000^{\circ}$ to $1,200^{\circ}\text{C}$. This change undoubtedly is not the same with all kinds of ores, but my experiments were conducted when using almost every variety of the mineral. According to the trials made, a mixture of one volume of carbon dioxide and two volumes of carbonic oxide at a temperature of 410° removed 10 per cent. only of the oxygen in Cleveland ore, and 37.8 per cent. from an artificially prepared oxide. The composition of the gases at the different depths, however, indicates in an unmistakable manner the nature of the action which is going on at any particular point. A table has been prepared from actual analyses of the gases, which gives the quantity of oxygen present for every 1,000 parts of metal produced; and to this is added the weight of carbon they contained. The results vary, but the general inference to be drawn from the observations made on furnaces of 80 feet is that, by the time the minerals have passed through a space of 8 feet of the depth they have to travel, all the oxygen susceptible of removal from the ore in the upper region is found in the gases, the remainder being retained until it reaches the zone of fusion. The same is the order of action, in a somewhat modified form, which was found to prevail in the case of furnaces 48 feet in height.

On casting the eye along the lines of figures, a somewhat remarkable circumstance is apparent, viz., that the quantity of oxygen per 1,000 of pig iron gradually decreases as the gases ascend, until they approach the upper region, when it commences to increase. This had been the subject of observation for many years without any complete explanation being given of its cause. Dr. Percy, among others, bestowed some attention to the circumstance without arriving at any opinion satisfactory to himself. It is a little extraordinary that, so far as I have seen, no notice has ever been taken of the fact that the carbon in the gases followed the same law. While engaged in investigating the action of furnace gases on the ore, a peculiarity was observed previously unknown to me, viz., that large quantities of carbon were deposited by the dissociation of the reducing gas, the action being $2\text{CO} = \text{CO}_2 + \text{C}$. Experimentally, I

ascertained that spongy iron, as well as oxide of iron, was capable of producing the change, and that 30 per cent. of carbon dioxide, mixed with the carbonic oxide, arrested the reaction, the temperature at the time being 420°. Dr. C. A. Wright, who subsequently became chief chemist of our laboratory, was asked to continue the examination. The conclusion arrived at was the impossibility of effecting the complete reduction of Fe_2O_3 or of any oxide by CO . On the contrary, when metallic iron known to contain no

oxygen was exposed to a current of this gas, carbon was deposited and oxygen absorbed. It would seem, therefore, that this absorption of oxygen by the iron and precipitation of carbon suffice to explain the disappearance of these two elements from the gases, and that they remain in this condition until the fusion of the iron, in contact with intensely heated carbon, liberates the oxygen as well as that portion of the carbon which is not absorbed by the metal in order to produce pig iron.

So far, then, as the analyses given in Table III. enable us to judge, instead of the upper two-thirds of a furnace being required for the purposes of reduction, no material change is effected after passing through 18 feet in a modern furnace of 80 feet in height. After this the composition of the gases, and, therefore, of the minerals, remains pretty steady until the vicinity of the tuyères is reached, with the consequences already referred to.

Of the excess of oxygen at the zone of combustion it is highly probable that a portion is due to the reduction of P_2O_5 , SiO_2 , SO_3 , and CaO . In the case of Cleveland iron I have estimated this at 54 parts per 1,000 of pig iron produced, but the average total oxygen, beyond that furnished by the blast in the first two instances given, was 130 parts. At this rate there must have been 76 parts of oxygen liberated from the oxide of iron, which is equal to 19 per cent. of that originally combined with the iron in the ore.

It may be appropriate here to refer to what may be taken as a typical expression of the working of a blast furnace in respect to the presence of carbon dioxide. An analysis of the gases is therefore inserted in Table IV., drawn from an 80-feet furnace at various levels, with the simple remark that it is improbable that carbon dioxide can exist for any length of time when exposed to incandescent coke at the temperature which prevails at the depths mentioned in the last two columns.

Something like 40 years ago the escaping gases from the blast furnaces, rich as they were in carbonic oxide, were permitted to burn wastefully on the surface of the minerals charged at the throat. This meant a loss of about 54 per cent. of the heating power of the coke. For reasons already given it was of course impossible to utilise much of this heat in the actual smelting of the ore, because of the necessity of preserving a large excess of carbonic oxide in the gases. This, however, constituted no reason why, apart from the furnace work itself, this vast quantity of gaseous fuel should not have been utilised, as it no doubt would earlier have been, had the ironmakers known, as they now do, its full value. To-day all the blast and other engines are driven and the air is heated at our blast furnaces by fuel formerly wasted, and this without any labour for stoking being required. In Great Britain alone the annual saving from this cause is fully equal to four million tons of coal.

In connexion with the other volatile products which accompany the iron smelters' work I will only mention ammonia. Some qualities of coal admit of being used in the raw state. In this case, as in distilling coal for illuminating purposes, ammonia is generated and may be collected. Instead, however, of the ammoniacal vapour being all contained in the hydrocarbons as in gas-making, it is diluted in addition with most of the fixed carbon as oxides and all the nitrogen of the atmospheric air used in its combustion.

Nevertheless Messrs. Bairds, of the Gartsherrie works, and others, are manufacturing large quantities of ammonia sulphate from the ammonia so obtained. A similar object is achieved by attaching the necessary condensers to the apparatus for coking coal. The process of distillation is then carried on in hermetically closed ovens heated by the combustion of the gases evolved. These, before reaching the fire-place where they are burnt, are deprived of their ammoniacal vapours by passing through condensers provided for the purpose. Previous, however, to this being done, the waste heat from the coking process had been applied for generating steam, so that at certain collieries in the county of Durham all the mechanical power is obtained without any coal being specially burnt for this purpose.

Before speaking of the next and last great improvements in connexion with my subject, I should like to say a few words, and a few words only, respecting steel, a well-known and most valuable compound of iron and carbon. Let me first observe that it seems improbable that this substance was not earlier known to the ancients, as was at one time supposed. The facility with which the metal combines with carbon renders it very unlikely that acieration would not occasionally take place when iron itself was the object of the manufacturer. Certain it is that Agricola, who wrote in 1556, describes in Latin a mode, apparently as well known as that of making iron itself, of making *Acie*. The engraving in his "De re metallica" shows bars of malleable iron placed upright in a charcoal fire resembling that of a Catalan hearth. These, after an exposure of several hours to the incandescent charcoal and hot carbonic oxide, were found changed to steel and employed as such.

After the invention of the blast furnace, pig iron was placed in a similar hearth to the Catalan, and while in a melted state a blast of air was directed upon the molten metal, until just as much carbon remained with the iron as constituted steel. This mode of procedure continued to be practised long within my own recollection, and may, for what I know, still be followed in some districts. The subject of steel-making occupied the attention of Hassenfratz, of Réaumur, and others, but practically the only process followed until 1865 was the well-known one of cementation.

Since the days of Fourcroy it had been ascertained that in addition to the iron carbon was an essential ingredient in cast metal, but invariably accompanied by more or less silicon, and whenever the minerals contained sulphur or phosphorus these metalloids were also present. The nature of the actions employed for ridding the product of the blast furnace of these substances so as to render it malleable had also been carefully examined and explained by the light of scientific investigation. The manufacturer had, it is true, learnt by experience and observation how to produce an article of excellence without much knowledge of the science of his art. Among other things he ascertained that to obtain a ton of wrought iron he required the heat of an equal weight of coal in the puddling furnace; but he did not know, nor did even men of science, I think, ever dream, that the oxidation of the metalloids in the pig iron, and that of a small portion of the metal itself, would afford heat enough to enable the workman to dispense with the use of all coal in the process of conversion. When, therefore, the iron trade was informed of this in a paper read before the British Association in 1856, entitled "A mode of making iron without the use of fuel," its author, Henry Bessemer, was set down by the iron trade as a deluded enthusiast. At that period I doubt whether 10 pounds of wrought iron had ever been seen in a state of fusion at one time. Bessemer, in his description, however, spoke of melting tons of it with no more heat than that afforded by the rapid oxidation of about 5 or 6 per cent. of the weight of the pig iron used. Not only, therefore, was the subject one of economic but also of high scientific interest. Nevertheless, a mere statement of the title of the paper was all the notice bestowed by our predecessors in their "Transactions" on a discovery which has revolutionised the art of making iron. It is quite true that for some time it appeared as if the scientific aspect of the question were to constitute its only recommendation, for the malleable iron made in a Bessemer converter proved unmanageable when hot, and destitute of strength when cold. Finally it was ascertained that phosphorus was the source

of the evil, and further, that while carbon and silicon could be almost entirely removed from the molten metal, this third metalloid remained unaffected by the treatment. The extent to which the hurtful influence of phosphorus makes itself felt in the wrought iron obtained by the Bessemer process is somewhat remarkable, because while two- to three-tenths per cent. is often present in puddled bars of fair quality, probably no consumer would accept Bessemer steel when it contains half of this amount. The first success was obtained in Sweden, where, by using pig iron containing a mere trace of the objectionable substance, a product was obtained which was satisfactory. For many years the beneficial effect produced by manganese on steel had been well known, and it occurred to R. F. Mushet, son of David Mushet, one of, if not the earliest scientific metallurgist in the United Kingdom, to try its influence in the converter on iron made from the hematite iron of the West of England, which contained from 0.5 to 1 per cent. of phosphorus. This addition, apparently by its removing occluded or combined oxygen in the molten iron, afforded the necessary relief, and the operation being one of extreme simplicity, enables steel or wrought iron to be produced at a greatly reduced cost. To such an extent has this been carried, that ore is brought by sea over a distance of 1,000 miles to Middlesbrough, and from it steel rails are made more cheaply than a greatly inferior article of iron can be produced from the abundant and economically wrought bed of ironstone found within a couple of miles of that town. As an example of the facility of conversion may be adduced the fact that the molten metal is brought direct from the blast furnace, turned into steel or ingot iron as the case may be, and the heat evolved by the operation is sufficient to enable the product in many cases, without further use of fuel, to be taken direct to the mill and rolled into a finished bar.

We have just seen that 1 per cent., or thereabouts, of phosphorus renders steel or ingot iron valueless; in like manner very insignificant variations in the quantities of carbon or silicon materially affect their quality. Now the blow, as it is termed, in a Bessemer converter may be accomplished in from 12 to 15 minutes. It is clear that therefore the opportunity of ascertaining the precise quality of the steel is one of very short duration. It is, I think, not disputed that a product can be obtained by this process possessed of very high, if indeed not of the highest, excellence, but it is also pretended that the quality is not sufficiently uniform for certain purposes. The ordinary reverberatory furnace is incapable of affording the necessary temperature for melting steel or wrought iron, but by employing the fuel in a gaseous state, and by heating the air and gas before they are brought together, as is done in the valuable furnace suggested by the Messrs. Siemens, the heat is so intensified that wrought iron in it is rapidly fused. Steel is now largely made in such furnaces, either by mixing wrought and cast iron, as proposed by M. Pierre Martin, or by means of cast iron alone, when the carbon is removed by the addition of iron ore and some limestone, in which case, by the agency of the ore, the metalloids are oxidised and removed from the bath of iron. Some hours being required for this sufficient opportunity is afforded for ascertaining the progress of the operation.

The cause of the iron in the Siemens furnace as well as in the Bessemer converter retaining its associated phosphorus began in time to attract the attention of chemists. In each case the expulsion of the metalloids is effected by oxidation. The carbon is gasified, and the silicon on being acidified is absorbed and forms a slag containing usually 45 to 50 per cent. of silicic acid. In the presence of such an excess of this substance, any phosphoric acid, if formed, could not be absorbed by the slag. It was the late M. Gruner, of Paris, who, in 1867, first pointed out this fact, and he it was who first recommended the use of lime in order to render the slag basic instead of acid. Further, in order to avoid the presence of silica, he recommended at the same time that the converter should be lined with lime instead of with fireclay.

The same subject engaged my own attention, when guided by the fact, that as oxide of iron in puddling was capable of acidifying and removing a large quantity of the phosphorus as iron phosphate, it might be possible

to make this removal more complete by some modification of the temperature of the furnace. This was found to be practicable without reducing the carbon below the point necessary for the easy fusion of the metal. The result of these experiments was communicated to the Iron and Steel Institute in March 1877, when it was shown that pig iron containing 1.75 per cent. of P could in a few minutes have this reduced to .2 per cent. This process is now being used in the United States for freeing cast iron from most of its associated phosphorus.

The rapid destruction of the ordinary Bessemer converter led Mr. G. I. Snelus to consider the practicability of using a lime lining, and on experimenting with this on a working scale he confirmed the opinions previously enunciated by Grüner by observing that the presence of lime had removed a considerable quantity of the phosphorus. These discoveries constitute the foundation of the very important basic process of Messrs. Thomas and Gilchrist, which consists in adding lime to the molten steel in a converter constructed on the principle described by Mr. Snelus. Considerable difficulty had, however, been experienced by this metallurgist in the attachment of the lime lining to the walls of the converter. This important question was solved by Mr. Edw. Riley by exposing dolomite to a very high temperature in order to prevent further shrinking, and then grinding it and mixing the powder with coal tar. This formed a species of cement which is applied to the sides and bottom of the converter in the form of bricks or as cement. Doubtless, simple as the idea is, it has greatly contributed to the success of the basic process.

The acidification and subsequent transference to the slag of the phosphorus by the basic treatment has led to its application to agriculture. For this purpose the slag is ground to a fine powder and sprinkled over the land without any further preparation. By this operation an indispensable element of animal life is derived from the remains of living creatures which, ages ago, found a grave in the ferruginous mud destined to become the great Cleveland bed of iron-stone.

Before closing this portion of my official duty, I cannot refrain from tendering to chemists an assurance of the great advantage the manufacturers of iron feel they have derived from the lessons taught them by chemical science. I am the more anxious to do this because we, among others, have been reminded that we are losing the supremacy among industrial nations which we once enjoyed, for want of that knowledge of chemistry which is more assiduously cultivated abroad than it is in our own country. I am not prepared to deny that the opportunities for acquiring a scientific education are less generally spread here than is the case in France, Germany, or Belgium, but for this the nation, and not the iron trade in particular, is responsible. It must also be admitted that as manufacturers we no longer stand so far above other lands as we formerly did. In this result any differences of education are in no way concerned, for if I were to classify the nationalities of the various inventions enumerated in the course of my remarks the fears of those who are alarmed at the appearance of a Belgian girder or a German steam-engine on our shores would, I think, be allayed. Perhaps I may be allowed to offer a very few words on the technical side of this important question of education. Much I shall not be able to say, because I have not yet been able to learn the precise position which the subject occupies in the minds of its most earnest advocates. If it means, as is sometimes alleged, a system by which, along with scientific instruction, manual dexterity in the use of tools or a practical knowledge of various manufacturing processes has to be acquired, I confess I am not sanguine as to the results. Certain I am that if foreign workmen are more skilful in their trades, which, as a rule, I doubt, and which in the iron trade I deny, this superiority is not due to scientific training in the manner proposed, for in this they possess, so far as I have seen, no advantage over our own workmen. My objection to the whole system is the impossibility of anything approaching a general application being practicable. I have not a word to say against the rudiments of science being taught wherever this is possible. The knowledge so obtained may often give the future work-

man a more intelligent interest in his employment than he at present possesses, but I think they who expect much good to attend such a thin veneer of chemistry or physics do not take sufficient account of the extent of the knowledge already possessed by more highly educated men who are now directing the great workshops of the world. It is by extending and enlarging this that substantial aid has to be afforded to industry and science, and not by teaching a mere smattering in our primary or any other schools. In the case of young people who from necessity must leave the schoolroom at an early age, my own leaning is towards the present system, with the addition of drawing and some natural science. By these, certain important lessons are taught, which, if not followed under the discipline of the schoolmaster, run some risk of being entirely neglected. After this, probably, the playground will be found more useful and much more popular with the schoolboy than trying to learn a trade by means of tools which, before he has to use them in earnest, may be thrown into the scrap heap.

As a national question the attention of the Government, Imperial or municipal, ought to be directed to the importance of establishing in all great manufacturing centres, institutions resembling the Physical College of this city. These should consist of appropriate and even handsome buildings, properly furnished with all the instruments and appliances required for teaching the sciences in their practical bearings on industrial pursuits. In Newcastle, as well as in other places, this has been done on a fairly ample scale, and the advantages the College of Science in this city is capable of affording are offered on such terms that no one can plead expense as a barrier to mental improvement.

Bearing in mind the importance of the subject, and remembering, as my colleagues and myself do, the difficulties we have had to encounter, and those we have still before us, I am strongly of opinion that the erection and maintenance of colleges of science should not be left to the accidental liberality of the few, but should be taken in hand by the nation at large.

On Alloys of Iron and Silicon. R. A. Hadfield. A paper read at the Paris meeting of the Iron and Steel Institute, 1889.

THE alloying of elements, other than carbon, with iron is a comparatively new field, and possesses special interest, not only to those concerned and engaged in the treatment of metals, but also to those who study the physical properties of substances. As the properties and nature of alloys of carbon and iron are fairly well understood, it is hardly necessary to consider them here, and in order to narrow down the considerations dealt with in this paper to a practicable limit, attention will be confined solely to alloys or mixtures of which metallic iron and silicon form the principal constituents.

An investigation of the properties of manganese steel, *i.e.*, an alloy of iron and manganese, was placed before this Institute by the author some 12 months ago, and its physical properties have been fairly well determined, as compared with alloys of iron with other elements. This was the more practicable owing to the fact that the manufacture of "cast iron" alloys of manganese, that is, ferro-manganese, had been for some time past in a very advanced state. In other words, by the cheap production of the alloys known as rich ferro-manganese, a material containing 80 per cent. of manganese and 5 per cent. to 7 per cent. of carbon, the residue being iron, has enabled experiments to be readily carried out by further alloying such rich manganese products with pure iron.

Mr. Turner's paper, read at the British Association Meeting, Bath, last year, described experiments with steel containing from 10 per cent. to 50 per cent. of silicon, and the details were fully given in the "Proceedings" of the Institute. The writer was asked by Mr. Turner and the British Association committee to investigate the effect of higher percentages of silicon, and he thought that the result of his inquiries might also be of interest to the Institute.

The subject of alloys of iron and silicon has for some years occupied the writer's attention, but it was not until lately that rich cast-iron alloys of silicon, *i.e.*, ferro-silicon,

have been obtainable, and even now they cannot compare in richness of silicon with that of the manganese in ferro-manganese. The highest ferro-silicon yet made contains not more than about 18 per cent. to 20 per cent. of silicon. Fortunately, however, owing to the peculiar fact, noticed more fully further on, as to its lowness in carbon, this is much better fitted for experimental work, as compared with, say, 20 per cent. ferro-manganese. Such a percentage of silicon, though comparatively speaking not so high, is sufficient to enable a suitable experimental material to be made, *i.e.*, a resultant material not containing too much carbon to interfere with an examination of the effect of the metalloid silicon upon the metal iron. Thus while in the case of rich spiegel or ferro-manganese the carbon present amounts to some 5 or 6 per cent., the 20 per cent. ferro-silicon, on the contrary, contains comparatively little carbon—always under $1\frac{1}{2}$ per cent. and often under $\frac{3}{4}$ per cent.—so that by means of this cast-iron alloy, when further diluted or mixed with pure iron, the malleable material or steel produced practically contains but little carbon. The curious fact that ferro-silicon alloys, as they rise in silicon, diminish in carbon, was first noticed in some laboratory experiments 18 years ago by Mr. Edward Riley. This will be again referred to further on. Whilst the scope of the experiments described in the present paper is in no way to deal with material other than malleable compounds of iron and silicon with small quantities of iron and manganese, it may be useful to give some general reference to previous experiments.

The only commercial employment of silicon with other metals is that of silicon bronzes. Silicon is stated to act upon the copper in a similar manner to phosphorus. The qualities of such alloys are great strength and tenacity, high electrical conductivity, and resistance to corrosion. Wire made of this material is stated to have a conductivity of 80 per cent., and a tensile strength of about 36 tons per square inch.

Mr. Warren, in a recent number of the "Chemical News," states that silicon, when in the nascent state, converts platinum into a brittle silicide, or by heating graphitoid silicon in contact with platinum to a full red heat, combination at once takes place, resulting in a brittle regulus containing as high as 10 per cent. silicon, which is fusible at a red heat, and breaks with a crystalline fracture.

Silver and gold are reported as not presenting any great affinity towards silicon, but on heating a mixture of potassium silico-fluoride with either silver or gold in an amorphous condition to a high temperature, a well-fused regulus of silicide of the metal may be obtained. In the latter instance, an alloy containing 5 per cent. of silicon is almost as brittle as antimony. Silver, when alloyed with 10 per cent. of silicon, is stated to have a slightly red tint.

Rich cast-iron alloys of silicon are now usually described as ferro-silicon and silicon-spiegel respectively, the latter containing manganese in addition to silicon. Silicious alloys of cast iron were usually known as glazed pigs, owing to their peculiar glazed appearance when fractured. It is curious that this very material—burnt pig, as it was often called, and only then made accidentally—was formerly thrown on one side as useless, whereas now it is made purposely on a commercial scale and in large quantities—another of the many proofs of the advantage of bringing scientific knowledge to bear upon industrial metallurgy. Such ferro-silicon, by itself, is perfectly useless in the refinery or puddling furnace, or for iron castings. The early samples of silicious iron seldom contained more than from 1 per cent. to 6 per cent. of silicon; but Mr. Riley, of London, in 1872, was the first to point out that rich ferro-silicon was likely to play an important part in metallurgical industry. By means of laboratory experiments he made in the crucible samples containing as high as 22 per cent. of silicon. He also discovered that as silicon increased carbon decreased, until with 20 per cent. of the former the latter is not present in quantities of more than $\frac{3}{4}$ per cent. to 1 per cent., and the greater part of this small amount existed as graphite. Spiegeleisen and ferro-manganese are the richest carbon alloys that can be produced, and they contain about 6 per cent. of carbon; ordinary cast iron rarely exceeds about 4 per cent., and never contains more than about $4\frac{1}{2}$ per cent. So strong, however, is the action of silicon in preventing carbonisation, even in the presence of a large excess of carbonaceous fuel, that in silicon-spiegel—an alloy of iron, manganese, silicon, and carbon, and notwithstanding the presence of a large amount of manganese—it (that is, the silicon) has still the upper hand, and prevents, as in the case of ferro-silicon, carbonisation taking place. A few typical analyses of ferro-silicon, silicon-spiegel, ferro-manganese, and spiegeleisen may be of interest here (see Table I.), but for a fuller description, and of the methods

TABLE I.

	ANALYSES PER CENT.				REMARKS.

These analyses are from the paper of Mr. Holgate, Assoc. R. S. M., Darwen, on "The Manufacture of Ferro-Manganese and Ferro-Silicon in the Blast Furnace."

of manufacture employed in their production, reference is given to Mr. Holgate's admirable paper on "The Composition of Ferro-Manganese and Ferro-Silicon made in the Blast Furnace." The writer is indebted to this paper for the analyses in question. Four of the samples quoted represent spiegele and ferro-manganese, and it is interesting to note that, as the manganese rises, there is a gradual increase of carbon up to as high as 7 per cent. A noteworthy fact is, that if silicon, even in 50 per cent. ferro-manganese, is allowed to reach 4 per cent., the carbon is at once much reduced, in some cases to the low amount of about 2½ per cent. This action is still more intensified in the alloys known as silicon-spiegele or silicide of manganese, of which two analyses are given. From the latter it will be seen that, provided the silicon exceeds 10 per cent., the carbon is reduced to an exceedingly low point, and that although manganese may be present even in comparatively high percentages, this is quite immaterial. This decrease of carbon takes place both in the combined and in the graphitic form, but principally in the former. A very valuable property of these spiegele alloys is the fact that they contain practically no sulphur, the much-dreaded enemy of the steel-maker.

It will, therefore, be seen that in the blast furnace, somewhat strange to say, silicon cannot be reduced unless carbon is also present, and yet, when reduction of silicon occurs with the production of highly silicious iron, carbon is practically absent in the resultant material. The late Dr. Percy, more than 20 years ago, referred to this in his "Metallurgy," and said that, according to his experience, no reduction can take place when silica and iron, without carbon, are heated together, even at the highest furnace temperature. Possibly this might now be accomplished in the powerful electric smelting furnaces, and it would be interesting to know whether alloys as rich in silicon as the present valuable alloys of ferro-manganese are rich in manganese could be produced. If so, without doubt, considerable employment could be found for them in metallurgical industry.

Alloys or compounds of iron, carbon, and silicon, non-malleable in their nature and coming under the term "cast iron," have been thoroughly investigated in this country by Mr. T. Turner of Birmingham, and the results have been placed before this Institute, so that it is unnecessary to do more than touch upon this matter here. Great credit is due to this investigator for the lengthy and valuable researches he has made in the direction indicated, as also to Mr. Keep, of Detroit, U.S.A., who has lately presented interesting papers on the same subject to the American Institute of Mining Engineers. Mr. Keep sums up so well the general results of all investigations up to date, that it may be well to briefly mention them, especially as some of the remarks apply, to some extent, to the malleable compounds or alloys of iron and silicon now being described. Both Mr. Keep and Mr. Turner find that white carbonaceous cast iron, which would invariably give porous and brittle castings, are made free from honeycombs and possess much greater strength by the addition of comparatively small amounts of silicon. The latter result is one which was considered contrary to previous experience. If further additions are made, say up to 2 per cent., the iron becomes grey, and at this point the maximum strength is obtained. If more silicon is added, although the iron becomes still more grey, it also becomes weaker. By a still further addition a closer grain results, but the iron is even more brittle than in its white condition. Too much silicon also produces, as in the silicon steel now being described, lack of fluidity and greater shrinkage. Mr. Keep thinks that silicon in cast iron is evidently to some extent combined with the iron and carbon, but whether it exists also in a form corresponding with graphitic carbon mechanically mixed with the remaining mass, is a question still in dispute and unanswered. As now well known, the principal effect of silicon is to change the carbon from the combined to the graphitic state. One point particularly mentioned by Mr. Keep, and an important one, is that silicon irons have always had the reputation of imparting fluidity to other brands, and naturally this was at first supposed to be owing to the silicon added. It has now been found that this is not directly so, and that it is from the fact that the silicon present causes an increase in the quantity of graphite, and

consequently a more fluid cast iron. Silicon is not, therefore, directly the cause, except by its indirect action on the carbon.

In conclusion, on this point, as Mr. Snelus said more than 17 years ago, it is generally supposed that the absorption of much silicon tends to set free the carbon in the graphitic state. No statement more concisely expresses the influence of silicon on what is termed cast iron than that given some eight years ago by Mr. C. F. King, of Newport, U.S.A., in an able paper read before the American Institute of Mining Engineers on "The Chemical Action of the Bessemer Process." He said it is due to the presence of silicon in pig iron that carbon is set free on cooling, and it is in proportion to the diminution of the silicon that the carbon remains chemically combined. Mr. King gives a diagram showing the rate of elimination of the metalloids in the process named, and it is a somewhat remarkable coincidence that the percentage point (1·8 per cent. Si) where the diminishing silicon curve cuts the combined carbon and graphitic curves, is exactly that which gave the maximum tensile strength in the material made by Mr. T. Turner, and later by Mr. Keep, in their numerous tests as to the effect of silicon upon cast iron. The diagram referred to and given (Diagram I.) shows that by a diminution in the silicon highly graphitic pig iron becomes rapidly mottled, and eventually white, although practically none, or but little, total carbon is oxidised; and this, as far as can be seen, is solely by the fall of the silicon from 2·50 to 1·70 per cent. Whilst, therefore, Messrs. Turner and Keep show that white iron can be converted into mottled, and eventually grey, by means of additions of silicon, this diagram shows the converse, namely, that with silicon abstracted cast iron becomes mottled and eventually white.

Outside, one might say ever within, the laboratory, the properties of the metalloid silicon or silicium are but little known. No fuller details can be found than in that part of Dr. Percy's "Metallurgy" relating to silicon, where all the methods for its production on a laboratory scale are given.

It is ordinarily described as a non-metal, very hard, dark brown in colour, a non-conductor of electricity, lustrous, not readily oxidised, and soluble in all ordinary acids, with the exception of hydrofluoric. It is said to resemble carbon in its general properties; others add that it exists like carbon in a graphitic, amorphous, and combined or adamantine form, but this has still to be determined.

Mr. Henry J. Williams, St. Louis, Missouri, U.S.A., this year presented a paper to the American Institute of Mining Engineers on "The Determination of Silicon in Ferro-Silicons, its Occurrence in Aluminium as Graphitoid Silicon, and a Study of its Reactions with Alkaline Carbonates." As the latest investigation of this kind, it may be well to refer to the experiments. Mr. Williams' method of determining the metalloid was by means of fusion with sodium carbonate, the idea being to dissolve it as soluble sodium silicate, and leave the iron in a very spongy and finally divided condition, so as to be readily attacked by acids. He noticed some curious facts during fusion. As soon as the sodium carbonate was thoroughly melted and the heat reached its maximum, the reaction became very violent, bubbles of gas (carbonic acid) rising to the surface and bursting into flame. This had been noticed before by another observer making experiments of similar nature with graphitic pig iron. Mr. Williams was, however, somewhat puzzled, as the ferro-silicon with which he was experimenting was high in silicon and comparatively very low in carbon, yet it gave the same result. To ascertain why silicon acts exactly like carbon during the reduction, he endeavoured to obtain an iron entirely free from foreign elements—particularly carbon—while containing high silicon, but he was unsuccessful. He found the desired condition realised in the aluminium of commerce, most of which, in spite of its name, he states contains not less than 3 per cent. or 4 per cent. of silicon, but, of course, no carbon. He found that a large part of the silicon in such aluminium seemed invariably present as an allotropic modification of that metalloid, crystallising in fine glistening black plates resembling some forms of graphite, and he considered that this was evidently the graphitoid form of silicon which Deville has mentioned in connexion with aluminium, but

which has not yet been isolated or found to exist in iron. Dr. Percy mentioned at length the same fact, and describes the material as resembling graphite from iron-smelting furnaces, and as being hard enough to scratch glass, with a specific gravity of 2.49. As regards, however, the form silicon may take in cast iron or steel, Mr. Keepe considers that, whether it exists in a state corresponding to graphitic carbon, and mechanically mixed with the remaining mass, is still a question in dispute. Mr. Holgate, of Darwen, also, in the paper before referred to, after making many analyses, says he has never found any evidence as to the existence of graphitic silicon in such alloys, though he has noticed some slight difference in the behaviour of silicon when dissolved in acids. Mr. Turner, in his paper some two years ago, after carefully investigating this point, both by means of experiments of his own and of those of Sir Frederick Abel, Mr. Snellus, and others, says that it may be considered that in a vast majority of cases, at least, silicon has only one form. Finally, therefore, the practical metallurgist has at present apparently no means of readily determining this point, although he may have reason to think that silicon does vary its form in cast iron or steel.

In metallurgical literature but little reliable information is to be found as to the effect of silicon upon iron. Mr. Howe, in his excellent work on "The Metallurgy of Steel," gives an excellent *resumé* of what has appeared. Some 14 years ago, in America, good results were promised by a process which was to use "Codoris, or silicon ore," as it was termed. This was to dephosphorise or neutralise the phosphorus in the metal under treatment. Only a few years back the writer had reason to investigate this matter in America, but found that this so-called puddled silicon iron or silicon steel contained no silicon.

Referring now to the consideration of silicon alloyed with the metal iron, the common belief has been that steel which has to be used in its forged state should contain practically none, or as small an amount as possible. Any quantity exceeding .10 per cent., or up to .20 per cent. at most, has been considered to be highly injurious. "Give a dog a bad name" is well illustrated in the present case, as will be seen from the results and tests given. At any rate, it may be safely said that silicon has been blamed in a somewhat hasty manner. This blame may be well deserved in alloys of carbon, silicon, and iron, as such alloys, as regards ductility, have no doubt proved unreliable and of little value, but the blame has been put at the door of silicon, whereas it is now proved that silicon alloyed with iron, provided carbon is absent or only present in small amounts, gives good tests as to toughness and malleability. It will be seen that $1\frac{1}{2}$ or even 2 per cent. may be present, and yet the material may possess 25 to 30 per cent. elongation; whereas the same percentage of carbon alloyed with iron would give a product barely malleable and one possessing but little elongation under tensile stress. Whilst, therefore, the common belief that alloys of carbon, silicon, and iron are brittle or even dangerous is quite correct, the cause is not due to silicon only, but to the combination of silicon with carbon and iron, a case parallel to some extent to that pointed out by the well-known Terre-Noire Company's experiments, where it was proved that phosphorus may be present in iron provided the carbon is low and the manganese high, a fact (that is, as regards phosphorus) still more prominent in wrought irons. As also pointed out by Mr. Howe, "Silica is often mistaken for silicon; who knows how far it is responsible for this metalloid's bad name?" This was actually noticed by Mr. Turner in test bars of steel containing comparatively low percentages of silicon, that is, under .5 per cent., much of the silicon present being in the oxidised condition.

Also, according to M. Gautier, there is a difference between steel made with silicon only and that with silicon and manganese, i.e., between a product made by adding ferro-silicon (carbon, silicon, and iron alloy), and that with silicon-spiegel (carbon, silicon, manganese, and iron alloy), and he mentions the following interesting experiment by his then colleague, M. Pourcel.

In a porcelain tube were placed two receptacles, one holding steel made by adding ferro-silicon only, and the

other steel by an alloy of silicon-spiegel. A current of chlorine was passed until all the iron was removed in the state of chloride. It was then seen that in the first receptacle there remained a network of silicate of iron, preserving the original formation of the piece, whilst steel by silicon and manganese alloy left no residuum. Also that such steel with no manganese was red-short, lacked fluidity, and possessed other defects. The writer has, however, not noticed such difference in the material now described, which in its molten state pours well, the ingots forging easily, and up to 2 per cent. silicon the ductility in the testing machine being very good.

However, as suggested by Mr. Howe, possibly silicon may enter into different combinations in steel, some promoting, some impairing ductility and malleability. In favour of this is the fact that so many well-known scientists and metallurgists have utterly condemned in forged steel the employment of silicon, even if present in small amounts. Such strong opinions would not be expressed without good grounds, and a reasonable explanation for the apparent discrepancy noticed by different observers seems to some extent to be in the direction named. At any rate, the samples described in this paper, and containing up to 2 per cent., present a remarkable ductility and toughness both in the bending and tensile specimens.

The writer wishes it be understood that he does not claim that silicon should take the place of carbon. Smaller quantities of carbon produce the requisite hardness and different tempers required in the industrial application of steel, and, in fact, silicon alone does not produce a steel that will harden by water-quenching, thus in this respect resembling manganese steel. Still it is a somewhat remarkable fact that a steel (specimen C, Table II.) containing 1.60 per cent. of silicon, a metalloid ordinarily so much distrusted, stretched 35.10 per cent. (on 2 in.) with 54.52 per cent. reduction in area, and a test bar from the same material tested by Professor Kennedy, gave 24.30 per cent. (on 10 in.) with 58.30 per cent. reduction in area. Also had not the specimen D., tested by Professor Kennedy, broken in the threads (the diameter of the bar over the threads being only .93 in. against .898 in. of the tested part of the bar, too small a difference in the holding part), no doubt his test would have confirmed the writer's, that a material with even 2.13 per cent. of silicon can elongate 36.50 per cent. on 2 in. (equivalent to about 27 per cent. on 10 in.) with 59.96 per cent. reduction in area. So that whilst it may not be advisable to use silicon as a hardener in making steel, it is important to have proved that the brittleness noticed in ordinary so-called silicon steel is due rather to the combined presence of the two hardeners, silicon and carbon. It may be here mentioned that the ductility noticed cannot be attributed to manganese, which was only present in small quantities, about .20 per cent. to .30 per cent.

The material employed in these experiments was made by melting in crucibles good wrought iron scrap, low in sulphur and phosphorus, to which was added in varying and increasing quantities rich ferro-silicon containing 20 per cent. of silicon. The ingots, $2\frac{1}{2}$ in. square, were reduced by forging in the ordinary method to $1\frac{1}{2}$ in. square billets, then rolled down to bars $1\frac{1}{2}$ in. diameter.

The effect of silicon upon iron is as follows:—1. In its forged condition. 2. In its cast condition.

1. Forged condition. The forge reports that the material A. (Table II.) (.24 per cent. Si) did not forge well, cracking somewhat whilst being hammered, but all the other samples, B. to H. (.79 per cent. to 5.53 per cent. Si), when forged at a fair yellow heat, required no special care, thus clearly showing that silicon, even up to as high as about 6 per cent., does not destroy the malleability of the metal iron. Upon, however, exceeding this percentage the material is red-short, crumbles at a low heat, and notwithstanding the low percentage of carbon present (.25 per cent.) becomes really a species of cast iron. It should also be here mentioned, that if the carbon had been higher, the point at which malleability ceases would have been with a much lower percentage of silicon. Nor is such red-shortness removed by the addition of manganese.

NOTES.—1. The tests by Professor Kennedy were made with a lever machine, those by the author with a hydraulic machine made by Sir Joseph Whitworth.

2. Unfortunately the tests made by Professor Kennedy were made on bars with holding parts only .03 in. larger than that under stress. The bars were thus much more liable to break in the thread; in two specimens this occurred, and the result of these two tests can hardly be considered complete.

3. In the Whitworth machine "permanent set" is usually readily observed by the "give" of the finger on dial; but to be quite sure on this point, the test pieces were taken out and very carefully gauged in a Whitworth measuring machine at successive and increasing stresses, until the permanent set was discovered by an actual increase in the length of the test bar.

4. The relative hardness of other substances determined by Professor Turner's sclerometer:—Lead, 1; copper, 8; softest iron, 15; mild steel, 21; good cast iron, 21 to 24; hard cast iron (scrap), 36; window glass, 60; very hard white iron, 72; manganese steel, under test; silicon steel, 20 to 36.

5. These tests will be found plotted on Diagram III.

It may also be here mentioned, that no return of strength takes place by a further addition of silicon, as is so specially characteristic of manganese steel. Any further addition merely increases its resemblance to silicious cast iron. Nor do gradually increasing percentages, as is the case with manganese steel, destroy the magnetic properties of the alloy, a 7 per cent. material seems quite as susceptible as ordinary iron or steel drillings.

As regards the results of the mechanical tests on this steel in its forged state, these are so fully detailed in Table II. (Tensile and Bending Tests), Table III. (Compression Tests), and Diagram III. that it is only necessary to add a few remarks here.

Apparently silicon, up to $1\frac{1}{2}$ or $1\frac{3}{4}$ per cent., added to iron, although increasing the limit of elasticity and raising the tensile strength, does not impair ductility; but after this the further increase of tensile strength noticed is only obtained with a serious loss of ductility. Apparently there is no sharp line of demarcation, but after exceeding about $1\frac{1}{2}$ to 2 per cent. further slight increases cause great changes in the characteristics of the material. In this respect therefore, its action rather resembles that of carbon, in contradistinction to the action of manganese, of which larger amounts are required to effect similar changes.

The fractures from the tensile test bars, up to "D," specimen (2.18 per cent. Si) are silky, after this completely and coarsely crystalline. As in the specimens in the cast state, neither annealing nor water-quenching seem to have any effect on the structure.

The annealed flat bending pieces, half inch wide by one-fourth inch thick, gave good results, specimens A., B., C., and D. (.24 per cent. to 2.18 per cent. Si) bending double cold without fracture, more like soft steel, and after being bent double the pieces were flattened close together cold without showing signs of fracture. Specimen E. (2.67 per cent. Si) also bent double cold, but broke in the radius with the last blow. F. (3.46 per cent. Si) was much stiffer, bent only to a right angle. G. and H. (4.49 per cent. and 5.53 per cent.) would not bend at all, and were exceedingly brittle. These bending tests were confirmed by Mr. Turner's experiments with bars of the same size. Up to D. specimen the samples bent to an angle of 180° , with one-eighth inch radius.

Pieces from the bars used for bending tests were also tested for weldability, but entirely without success. The writer's experience has always been that silicon is quite fatal to welding, notwithstanding that the contrary might be expected

from the fact that silica is of such material assistance in welding wrought iron.

As regards water-quenching or hardening, samples A., B., C., and D. (.24 per cent. to 2.18 per cent. Si) were unaffected, *i.e.* unhardened, by even the highest heat. Even if plunged at welding heat into water made specially cold, no hardening beyond a surface stiffening took place, nor did their toughness seem impaired by this treatment. Specimen E. (2.67 per cent. Si) was heated to an ordinary yellow heat, and plunged into cold water at about 70°F . This piece was much stiffened, but only broke on being bent double. Another piece of the same material, heated to a welding heat and plunged into water at about 52° , also proved very stiff, and only broke when bent double. F. (3.46 per cent. Si) this sample was only stiffened by being water-quenched at a welding heat. It was just as brittle as before, and had not hardened, being easily touched by a file. In this respect, therefore, *i.e.* as to being toughened by water-quenching, this material differs from manganese steel. The heating did not cause much alteration in fracture, the crystallisation being still open and coarse. H. (5.53 per cent.) was quenched both at ordinary heat and at a welding heat, and although the surface was skin-hardened, upon being fractured it was easily filed. These tests, therefore, clearly prove that silicon does not confer the same property as carbon does upon iron, *i.e.* of becoming hardened when dipped hot into a cooling medium. It should also be here stated that the whole of the samples were subjected to high heats, even to a welding temperature, without falling to pieces. In fact, as regards this point, they behaved more like mild steel, apparently proving that silicon itself does not cause iron to become red-short.

That silicon steel has a certain kind or degree of softness or lack of body compared with carbon steel is especially brought out in the compression tests (Table III.), where sample E., although apparently very hard and brittle (high in the scale of Turner's hardness tests, *viz.*, 33), crushed up 38 per cent. of its length under a compression load of 100 tons per square inch. A correspondingly hard temper of carbon or tungsten steel would not shorten more than 20 per cent., or if hardened, would remain unaltered. A very mild steel, containing not more than .20 per cent. of carbon, would not shorten much more than this sample containing over $2\frac{1}{2}$ per cent. of silicon. At any rate, therefore, silicon is not so powerful a hardener of iron as is carbon. Mr. T. Turner has tested this material in his sclerometer, or hardness testing machine, the results of which are given under his name in Table II.

In order to test this steel in the shape of wire, samples E. (2·67 per cent. Si) and G. (4·49 per cent. Si) were reduced to rods, and Messrs. Shipman and Co., of Sheffield, kindly undertook to draw them into wire. The G. material, though readily rolled into rods, would not, however, draw, nor did annealing soften or give it the requisite ductility. In the rod state the tensile strength was 59 tons per square inch, with 12 torsions in eight inches. Crucible carbon steel would stand about the same test, and Swedish Bessemer, with high carbon, is slightly higher in torsion, but lower in tensile strength.

The material E. was readily drawn to No. 20 B.W.G., standing 180 lb. tensile strength (64 tons per square inch), with 157 torsions in eight inches. Annealing lowered the tensile strength to 120 lb. (about 48 tons per square inch), and slightly increased the torsions to 169 in eight inches. The wire-makers endeavoured to harden both G. rods and E. wire, first in oil and then in water, but without success.

Professor Barrett, of Dublin, has kindly undertaken to determine the electrical properties of the steel wire just mentioned, but the results are not yet completed. About 12 months ago the writer, thinking that silicon might confer upon iron qualities suitable for the manufacture of magnets, sent to Mr. Bottomley, in Sir W. Thomson's laboratory, Glasgow, a forged sample containing 4·43 per cent. of silicon, and 18 per cent. of carbon.

The results of Bottomley's experiments, as will be seen from Diagram No. III., were unfavourable. He found that the material had less susceptibility and more retentiveness than good soft iron, and that it had enormously less retentiveness than hard steel suitable for magnet-making. The diagram shows two curves "A" and "B," "A" showing the retentiveness of the bar and "B" the susceptibility. The dotted curve "C" represents what the bar should be if it were suitable for magnet-making, and the dotted curve "D" what it would be were it good soft iron.

Considerable attention having been given to the curious non-magnetic properties of manganese steel, the writer was led to make the approximate tests detailed in Table IV., to see if iron, alloyed with other elements than manganese, would also lose its magnetic susceptibility. From the list given it will be seen that practically manganese is the only exception, for as regards ferro-chrome, it is only when very high percentages of chromium, and but comparatively small amounts of iron are present, that the material is not susceptible.

MALLEABLE FERRO-ALLOYS.

Malleable compounds of iron with other elements so far experimented upon (including carbon, silicon, sulphur, phosphorus, chromium, tungsten, aluminium, and nickel) are strongly susceptible to magnetisation.

Alloys of manganese and iron, however, form an exception to this. As is now well known in manganese steel, as soon as the manganese exceeds 8 or 9 per cent., the material is only attracted when in a finely divided state such as drillings or powder, and with further increase of manganese even this slight susceptibility disappears. The same fact is noticed as regards the non-malleable compounds of iron and manganese. Alloys of iron, nickel, and manganese are also not susceptible.

2. *Cast state.*—As might be expected, the whole of the samples are very free from honeycombs, but this soundness in the cast is only acquired at the expense of toughness or ductility. As regards this freedom from honeycombs, it may be of interest to state here that although silicon does produce soundness in steel, yet Mr. Holgate noticed that in making ferro-silicon of 13 to 15 per cent., there is in casting an unusually large outburst of gas, and the pigs are exceedingly full of honeycombs. A sample is exhibited among the specimens accompanying this paper. In watching a cast of material of this percentage from the blast furnace, he noticed that when the exterior of the pigs became almost solid, and whilst the interior was still liquid, the metal began to boil up, and frequently for 15 or 20 minutes some cwt. of metal in each bed boiled over, this going on until the pigs were quite set and solid.

It would be interesting to know what is the cause of this outburst, and the composition of the escaping gases. It has been stated in metallurgical literature that in some hot overblown Bessemer charges silicon may be present in considerable percentages, and yet the steel rise or boil over when poured into ingot moulds.

Silicon steel pipes or settles to a much greater extent than ordinary steel, and this in itself is a considerable disadvantage. Its fluidity when being poured is less than that of ordinary steel. The crystallisation or form of fracture of the lower percentages is somewhat like ordinary mild cast steel, but on exceeding about 2½ per cent. silicon a striking change occurs; the crystals become very large, glazed in appearance, and cleave somewhat after the nature of spiegeleisen. As this large

and marked crystallisation increases the material becomes exceedingly brittle, and if still further additions are made, the appearance of the material approaches silicon pig iron, and is non-malleable.

High percentages of silicon in the cast or unforged material causes a considerable increase in shrinkage or contraction. This point is already a difficult one with the steel-founder, who for many years has been on the horns of the dilemma, that whilst silicon increases soundness, it increases the tendency of castings to draw. In cast iron this fact of silicon also increasing contraction has been noticed by Mr. Keep.

Also, as in the forged so in the cast material, when the silicon exceeds about 2 per cent., and the peculiar crystallisation noticed in the samples exhibited commence, neither annealing nor water-quenching seems to have any effect in changing the structure.

It is well known that considerable difficulty is experienced in dissolving drillings of ferro-silicon; so tedious is the process, that recourse is usually made to the sodium carbonate process. This is not requisite with silicon steel, which requires only the ordinary hydrochloric acid method. The silica residue is very clean and free from iron.

A considerable number of estimations have proved that the silicon is very uniform and homogeneous in this steel. Analyses taken from different parts of the same ingot and bar give results very similar to each other. No traces of graphite are noticed, the carbon always being present in the combined form. If the material analysed is in the form of drillings, they keep their shape, the iron being dissolved out.

Experiments have been made with this steel in comparison with other material as regards its corrosion. Table V. gives the time of immersion in the sulphuric acid and the loss.

In conclusion, the author wishes it to be understood he does not claim that there is any field for the employment of such an alloy or high silicon steel as that here described. This paper is presented only for the purpose of scientific interest, and in order to place on record the actual effect of the metalloïd silicon on iron. Silicon cannot take the place of carbon; the latter has always the advantage of being more easily applied, and of producing a material more suited to the various requirements of users of steel.

It is also clearly proved by these experiments that silicon, unlike carbon, does not confer upon iron the property of becoming hardened when water-quenched.

The following table gives the specific gravities of the silicon steel, as well as that of ferro-silicon:—

Samples of ferro-silicon containing 16 per cent. silicon yet honeycombed.

Silica from silicon steel.

Also other samples.

Roasting Iron Ore. The Ironmonger.

STERLING G. Valentine has made a valuable series of experiments in the desulphurisation of pyritiferous iron ores, from which he draws the following conclusions:—Heat alone, without access of air, can remove, at best, only one-half of the sulphur present. Atmospheric oxygen is absolutely necessary for a proper desulphurisation. Even at a low heat ore is properly desulphurised if air can gain access freely to the FeS_2 in it. Sulphate of iron can be decomposed by heat equally well with or without air. In order that the residuum of sulphur in roasted ores may consist, so far as possible, of sulphates, the roasting must be effected with free access of air. Fusion or sintering of ore is likely to prevent any further desulphurisation. Sintering does not allow much of the remaining sulphur to be in the form of sulphate. Fusion, hence, should never occur in roasting, except after continued heating in air at a lower temperature. Ores cannot be properly desulphurised in the upper part of the blast-furnace. An efficient roaster must allow easy control of heat, abundant air access to the hot ore, and rapid removal of the products of combustion.

Notes on the Iron and Steel Manufacture in France in 1887. Prof. S. Jordan. Iron and Steel Institute, Paris Meeting, 1889.

COAL AND COKE.

Production of Coal and Coke in France in 1887, compared with 1877.

Coal-fields.	1877.	1887.
	Tonnes.	Tonnes.
Northern coal-field	6,720,000	11,317,000
Loire coal-field.....	3,340,000	2,989,000
Gard coal-field.....	1,660,000	1,831,000
Burgundy and Nivernais coal-field ..	1,380,000	1,497,000
Central coal-field	1,020,000	994,000
Aveyron and Tarn coal-field.....	975,000	1,076,000
Auvergne coal-field	240,000	291,000
Iterault coal-field	238,000	208,000
South Vosges coal-field.....	186,000	186,000
Creuse and Corrèze coal-field.....	178,000	153,000
Western coal-field	237,000	136,000
Western Alps coal-field	132,000	132,000
Total for coal and anthracite	16,305,000	20,810,000
Provence and Alps brown coal-fields.	470,000	457,000
Sundry brown coal-fields.....	30,000	21,000
Total for brown coal	500,000	478,000
Sum total.....	16,805,000	21,288,000

N.B.—The French *tonne* is 1,000 kilos

It will be seen that the coal output of France has increased in 10 years by about 25 per cent., and that this increase has nearly altogether taken place in the Northern coal-field.

The coal consumption of France having been 31,191,000 tons for 1887 (instead of 24,144,490 tons for 1877), the foreign imports must have been 10,565,000 tons (including 4,046,000 tons of British coals), instead of 7,882,000 tons (including 2,867,000 tons of British coals), for 1887.

Coke.—As to this fuel the author can only repeat what he said in 1878. Coal is just now produced in France almost only in the improved coke ovens, called Belgian coke ovens, of the Smet, Coppée, or other analogous systems, in which the introduction of the coal to be carbonised is effected through hoppers placed in the arched ceiling of long rectangular and horizontal chambers or vaults, opened at both ends, and the extraction of the coke is effected by means of mechanical steam pushing rams. The vertical Appolt ovens are not now much in use; they are only to be seen at Blanzay, Creusot, and Bezenet. The obsolete beehive ovens are used only at one or two collieries, and can be seen in the exhibition of the Loire collieries; but their products are not intended for blast furnaces, and are only used for foundry purposes. The visitor can find in the exhibits at the Douchy, Escarpelle, and Dourges collieries some examples of improved plants for the manufacture of coke, and in some other collieries will be found specimens of the coke produced.

Coke is manufactured sometimes with only screened small coals, at other times with washed small coals, according to the purity of the fuel to be obtained. The so-called "washed coke" used for blast furnaces contains generally from 6 to 10 per cent. of ash; the unwashed ones contain 10 to 12 per cent., and often more. The small coals carbonised are seldom of only one origin; the coke-makers rather try to obtain economical mixtures by associating the dearer coking coals with the largest possible proportion of the cheaper non-coking coals, so as to come as near as possible to the limit of the property of coking. These mixtures are made with great care by means of various apparatus, such, for instance, as the Carr disintegrator. The coke-makers have, in that way, been able to notably lessen the cost of production of coke, owing especially to the use of the Coppée and other improved ovens, which produce good coke with coals that would not cake in the beehive ovens. Messrs. Seybel and Bernard exhibit in the "Palais des Machines" some drawings of improved coke ovens specially intended for the coking of meagre coals.

Messrs. Schneider and Co. have tried at Le Creusot a new form of vertical coke oven, known as the Bauer system; but the author would require some further data as to the results obtained in order to be able to speak of these ovens.

The application of coke ovens to the production of tar and ammoniacal salts has found a place in some collieries, as at those of Bessèges, Mais, Terrenoire, St. Etienne (Carvès ovens), and the Campagnac colliery (Seybel ovens); but commercial circumstances have not favoured the extension of the manufacture of by-products. The author believes that for some years past no other ovens have been built in France for that purpose; besides, the quality of the coals used here for the production of coke does not suit this special industry of by-products so well as the English or German coals.

SECTION II.—THE PIG IRON MANUFACTURE.

According to the official statistics, the comparison of the pig iron production in France for the years 1877 and 1887 is as follows:—

	1877.	1887.
Pig iron production:—	Tonnes.	Tonnes.
Coke pigs.....	1,372,000	1,547,000
Charcoal pigs.....	80,000	12,000
Coke and charcoal pigs.....	54,000	9,000
Sum total.....	1,506,000	1,568,000

SECTION II.—THE PIG IRON MANUFACTURE—*cont.*

	1877.	1887.
Number of furnaces in blast:—	Tonnes.	Tonnes.
Coke blast furnaces.....	133	84
Charcoal blast furnaces.....	69	12
Coke and charcoal mixed blast furnaces...	30	5
Sum total.....	232	101
Consumption of raw material:—		
Coke.....	1,900,000	1,800,000
Wood charcoal.....	120,000	15,000
Iron ores.....	3,323,000	3,453,000
Indigenous ores.....	2,346,000	2,298,000
Algerian ores.....	330,000	48,000
Foreign ores.....	647,000	1,107,000

These figures indicate that important changes have taken place during the ten years that have elapsed since the 1878 Exhibition.

The production of charcoal pig iron has continuously decreased, and now shows only an unimportant tonnage.

The smelting of iron ores with a mixture of coke and charcoal was a local and temporary peculiarity, and this practice is disappearing more and more, either because the blast furnace owners, who, being unable to use coke only owing to the smallness of their plant, mixed coke with charcoal in order to lessen the cost of production, have finally put their furnaces out of blast, or because they have decided to build larger furnaces, and to use coke alone.

The production of pig iron by means of coke is therefore now the only important branch of the French pig iron trade. The author reported to the Institute in 1878 as to the geographical distribution of the blast furnaces in France. The following statement will show the changes since that time:—

BLAST FURNACES IN BLAST.

Districts.	1877.	1887.
North and Pas-de-Calais district.....	16	12
Mourthe and Moselle district.....	32	31
Champagne district.....	59	14
Franche-Comté district.....	9	2
Central district.....	21	7
North-Western district.....	13	1
Perigord and Aveyron district.....	19	4
Pyrenees and Landes district.....	18	11
Loire and Rhone district.....	29	10
Alpine district.....	6	3
South-Eastern district.....	10	6
	32	101

The total number of blast furnaces has decreased more than one-half, but the pig iron production has nevertheless increased. From about 6,500 tons the mean annual make per furnace has increased to 15,500 tons, and, if the details were looked for, it would be found that the progress in this respect has occurred in the two first districts, and, above all, in the Mearthe and Moselle district, which, with less than a third part of the total number of the French furnaces, has produced more than one-half of the total annual make of pig iron.

SECTION III.—MANUFACTURE OF WROUGHT IRON AND STEEL IN OPEN FIRES AND IN PUDDLING FURNACES.

The introduction of the new and economical processes for manufacture of cast steel has effected great changes in the iron industry of France as well as of other countries. The following statement, taken from the official statistics, gives an idea of these changes since 1878:—

	1877.	1887.
Number of puddling furnaces (iron)	995	637
" " (steel)	51	35
Number of open fires (iron)	243	53
" " (steel).....	6	5
	Tons.	Tons.
Production of puddled iron	821,006	617,997
" of charcoal refined iron	63,487	16,864
" of puddled and charcoal-refined steel.....	20,273	12,532

These figures are sufficiently expressive, and the author does not think it necessary to discuss them specially.

SECTION IV.—MANUFACTURE OF STEEL IN CONVERTERS.

According to the official statistics, there were 24 Bessemer converters at work in France during the year 1877, but no data are given as to their output. The data for 1887 are as follows:—

Converters in activity	28
Output in 1887, viz. :—	Tons.
Rails	189,200
Bars	107,300
Plates and sheets	28,400
Total	324,900

The author cannot indicate separately the output of acid Bessemer steel and of basic steel; but the statistics allow us to estimate at about 143,000 tons, the quantity of basic steel contained in the 324,900 tons above stated. The producing power of basic steel in the French steelworks is, however, much greater than would be supposed from the above figures, as well as of acid Bessemer steel. Indeed, although the official statistics indicate that some 28 converters were at work in 1887, this only represents about two-thirds of the actually existing converters, which will number from 42 to 44. Some Bessemer steel works have been entirely idle in 1887, such as those of Terrenoire, Givors, Saint Nazaire, Pagny on the Meuse; while some others worked with only a part of their plant.

SECTION V.—MANUFACTURE OF STEEL IN OPEN-HEARTH FURNACES.

There were, in 1877, 51 open-hearth furnaces in France. Their number appears to have decreased in 1887, owing to the closing of the Sireuil Works, in which Messrs. Martin were the pioneers of this new manufacture, and to the reduced working of the Terrenoire and Besseges works. The official statistics furnish the following data for 1887:—

Number of open-hearth furnaces in work	69
Output in 1887, viz. :—	Tonnes.
Rails	13,709
Bars	90,498
Plates and sheets	39,557
Total	143,764

But the number of furnaces in working order in 1889 is notably greater, and may be estimated at about 75 furnaces of various systems and sizes.

Since the time of the introduction by Messrs. Martin of the new process in their Sireuil Works, the size of the open-hearth furnace has always been increasing. Instead of the 3 to 4-ton furnaces first used, 10-ton furnaces, 20-ton furnaces, and even, as in some steel works of the Loire district, 35-ton furnaces can now be found.

In reference to the manner of constructing the furnace, the majority are of the fixed type, the so-called Siemens-Martin furnace, designed at first by the Messrs. Martin themselves, and having regenerators situated underneath the hearth, and the reversing valves on one of the small sides. In two or three steelworks only can the Pernot furnaces be found, with a revolving circular basin or hollow hearth, or the Batho furnace, with a round hearth, supported by an iron plate, free underneath, and with round regenerators with plate-iron casing placed laterally and above ground. But the use of these varieties of the open-hearth furnace does not seem to extend very much in the French steelworks, which look as if they preferred the ordinary type. All these furnaces are heated by means of generator gases. Water-gas and petroleum have not yet been tried in France for that purpose, so far as the author knows. The number of casts in 24 hours varies according to the different works and types of furnaces, between two and four.

The most general mode of working is the scrap process. The ore process is not employed in France as far as the author knows, and the combined use of scrap and ore, as in the Laundore process, is only in current practice at the Allevard Works, as far as the author can say.

The nature of the lining varies in the different works, and according to the description of materials used. Sometimes the lining is acid, that is, it is made with sand, ganister, or silicious puddle; sometimes it is basic—that is, made with magnesia bricks or puddle (according to the system patented in 1869 by Mr. Emile Muller), or with dolomitic bricks and blocks; at other times the lining is neutral—that is, made with chrome ore (according to the Valtou-Remaury process). When the lining is made with chrome ore, Messrs. Valtou and Remaury state that no material is taken from the lining either by the molten metal or by the slag, so that no corrosion takes place, and it becomes possible to act on the metal either by scraps or by ores, or by various agents in such a manner as to effect a complete dephosphorisation, and to produce various descriptions of steel. Messrs. Valtou and Remaury exhibit drawings of furnaces neutrally lined, specimens of their chrome ore and linings, and products of some steelworks working their process. French steelworks, such as Fourchambault and Aulais, for instance, choose the neutral lining rather than the basic one, which, they say, is sooner worn out, and above all when some iron ore is used in the process.

The properly-called dephosphorising mode of working, that is, the conversion of truly phosphoretic pigs (such as those of Meinthe and Moselle) in cast steel by the open-hearth process, is not yet much used in France. This description of pig iron is sooner dephosphorised in the basic Bessemer converter. Mr. Fould-Dupont, however, shows in his beautiful exhibit (Central Gallery) cast steel of every form obtained in open-hearth furnaces from his Pompey pig iron.

On the other hand, in many steelworks, the basic or neutral lining is used for making open-hearth steel with ordinary pig and scrap, not free enough from phosphorus to yield good steel on an acid lining, and too low in phosphorus to be worked in the basic converter. Some of them are even working pure pig and scrap upon basic and neutral hearths, and produce soft and extra soft steels of very high quality; these steels being, besides, either simply carbon steels, or steels into whose composition enter silicon, manganese, and chrome, inasmuch as the open-hearth furnace is a very convenient and adaptable one, which allows the easy introduction and stirring of any reagent in the metallic bath.

Upon the whole, the modes of working in the open-hearth furnace are very diversified in France, not only owing to the acid, basic, or neutral lining, but also owing to the composition of the materials, pig iron, scrap, ores, and alloys employed.

SECTION VI.—MANUFACTURE OF BLISTER STEEL AND OF CRUCIBLE CAST STEEL.

The use of cementation or converting furnaces is somewhat stationary in France. There were, in 1877, 34 converting furnaces with an output of 1,717 tons of blister steel; in 1889 the number of working furnaces was 24 and the output was 1,491 tons.

The furnaces are not employed only for the carbonising of superior wrought-iron bars, intended for the making of shear steel or tool cast steel; they are also used for adding carbon to certain puddled steels and even to certain cast steels for special purposes.

In reference to crucible steel, the official statistics give, for 1877, 101 furnaces with an output of 7,252 tons; and for 1887 only 39 furnaces (containing 501 crucibles) have produced 7,532 tons. The old furnaces, heated by coke fires, and containing two or four crucibles each, are now to be found in a few inconsiderable works; the large steelworks employ actually nearly everywhere large gas Siemens furnaces, containing 20, and even 40 crucibles.

The crucible melting is not actually only employed for producing tool cast steel by the fusion of blister steel, or for making homogeneous iron by the fusion of pig iron with malleable iron. This mode of melting metals has now taken a prominent place in the manufacture of the new steels, in which several substances besides carbon are alloyed with iron, as can be seen in the Exhibition by inspecting the Unieux, Assailly, and Firminy exhibits.

At Messrs. T. Holtzer & Co.'s, M. Brustlein began, many years ago, and has continued since, practical researches and experiments with a view to ascertain the influence of some metalloids (such as silicon), and of some metals (such as manganese, chromium, tungsten, and copper), on the mechanical properties and the qualities of cast steels. These trials brought him to the manufacture in crucibles of some iron alloys, like ferro-chromium and others. In 1878 the Unieux Steelworks exhibited ferro-chromium and chrome steels, which were much admired. In 1889 these works exhibit chromium carburets, silico-chromium, ferro-chromiums of various percentages, silico-ferro-chromium, manganese-ferro-chromium—all these alloys being obtained in crucibles; and also a comparative series of different grades and kinds of steels, carbon steel, manganese steel, silico-manganese steel, copper steel, wolfram steel, chrome steel, and chrome-wolfram steel.

SECTION VII.—MISCELLANEA.

The researches and the chemical studies relating to iron metallurgy have been numerous during some years past; they have not been unfruitful for the iron industry. The basic or Thomas-Gilchrist process is one of their fruits, the importance of which cannot be contested. Messrs. Thomas and Gilchrist have been induced to make trial of their basic linings, as they told the author in 1878, by the scientific writings of the late Professor Gruener. The Rollet process, the Valtou-Remaury neutral lining, and others, can also justly be considered as results procured by the chemical laboratory.

Since the considerable increase of the new cast steels (Bessemer and Siemens-Martin) manufacture, these metals have been particularly studied by chemists, often associating themselves for that purpose with mechanical engineers, as can be seen by the writings of Mr. Deshayes on the relations between the mechanical properties of steel and its chemical composition.

But what appears to the author to characterise above all the scientific researches made in France on the metallurgy of iron during this period is the intervention of physical science in these researches. Metallurgists already knew the calorimetric studies of Messrs. Troost and Hautefeuille on the carburised, siliconised, and manganese pig irons. They possess now, among others, Mr. Forquignon's researches on malleable cast iron and steel, those of Mr. Pionchon on the calorific capacities and the physical changes of iron at high temperatures, the studies of Messrs. Osmond and Werth, engineers at the Crenost Works, on the intimate structure of steel; those of Mr. Osmond on the transmutations of iron and carbon in the malleable irons, steels, and

white pigs; and in all these works there have been used at the same time chemical analysis, calorimetry, microscopy, and even electrical measures. Visitors to the Exhibition can see in the Metallurgical Gallery an apparatus used in the Montluçon-Saint-Jaques Steelworks for studies of that kind—the Evard apparatus, for ascertaining and measuring metal dilatations at high temperatures. Besides, moreover, can be found the Mesuré and Nouel pyrometric telescope as employed for practically ascertaining the temperature of incandescent bodies, based on polarisation phenomena.

These various scientific studies have had an influence which is considerable over the French metallurgical works, although the author cannot possibly do more than allude to it. One of their results, and perhaps not the least important, is the considerable increase in the making and employment of steel castings in France, a fact which has forcibly impressed visitors to the Exhibition of 1889.

PATENTS.

Improvements in Extracting Gold and Silver from Ores or other Compounds. J. S. MacArthur, Pollokshields, and R. W. Forrest and W. Forrest, Glasgow. Eng. Pat. 10,223, July 14, 1888. 6d.

CHIEFLY improvements of Eng. Pat. 14,174 of 1887 (this Journal, 1888, 678). The ores are first treated with an alkali or alkaline earth, then washed with cyanide solution, and precipitated with freshly-prepared and finely-divided zinc. The improvements in the zinc process are claimed also for other than cyanide solutions.—T. L. B.

An Improved Method of Extracting Gold from the Various Auriferous Ores. C. T. J. Vautin, London. Eng. Pat. 11,399, August 7, 1888. 6d.

THE expense and delay of roasting gold ores is obviated by treating first of all with chlorine, bromine, or iodine, and then amalgamating. Claim is made for the combination of the two processes—chlorination and amalgamation.—T. L. B.

Improvements in Means or Apparatus to be Employed in Coating Metal Sheets with Tin, Terne, and other Metals or Alloys. J. G. Thomas, Llangennech, and G. H. White, Pontardulais. Eng. Pat. 11,854, August 16, 1888. 8d.

THE several processes from fluxing to finishing are here performed in one continuous operation. The plate passes first through a bottomless box contained in the upper part of the tinning pot; this box contains the flux supported on the surface of the molten metal. It is conducted thence by guides through the molten metal to a pair of rolls, whence it passes through a narrow neck to the grease pot at the entrance of which it is received by another pair of rolls. Between this second pair of rolls and the next pair or finishing rolls, which are arranged above the level of the molten metal, an enclosed guide is provided to conduct the plate. This guide passes above the level of the molten metal and enters a short distance into the grease, which is supported on the surface of the molten metal. Scrapers are also provided to remove any dross from the surface of the molten metal. As the guide encloses the surface of the molten metal through which the plate passes, there is only a small surface on which dross can form and it is thus readily removed. A second pair of finishing rolls is provided, whence the plate is conducted away as desired. The two pots are heated by separate fires, and by reason of the narrow neck both pots may be kept at different temperatures. Six claims are made.—T. L. B.

A New or Improved Process of obtaining Aluminium. B. J. B. Mills, London. From J. D. Bennett, Brooklyn, U.S.A. Eng. Pat. 12,343, August 27, 1888. 4d.

THE process consists of two main operations, the first is to roast a mixture of clay or other aluminous earth, alum, and salt; and the second is to heat in a retort the roasted material so obtained with whiting, asbestos, and lamp-black.

The aluminium is thus produced in buttons and globules, and is separated from the remainder by sifting. The function of the asbestos is to "prevent all slag from forming, and produce an ash whose porous character permits of the filtration and percolation of the globules of aluminium as they are formed."—A. W.

Improvements in the Manufacture of Sodium and Potassium. H. W. Wallis, London. Eng. Pat. 12,626, September 1, 1888. 4d.

"HYDRATED alkali" is powdered and mixed with 10 or 15 per cent. of carbonaceous material, also pulverised, and fed at intervals into a heated retort. It is claimed that this method is preferable to that (already known) of feeding the retort periodically with a mixture of fused alkali and carbonaceous material, both because of the extraneous heat needed to keep the mixture fluid, and of the alleged fact that a mixture so kept for some time becomes less easy to reduce.—H. B.

Improvements in and Connected with the Recovery of Tin, Spelter, Solder, and like Metals or Alloys from Scrap or Refuse Tinplate and other like Coated Metal Wares. R. C. Thompson, St. Helens Junction. Eng. Pat. 12,937, September 7, 1888. 8d.

AFTER cleaning, the material is heated to a temperature equal to or greater than that of the melting point of the metal to be recovered in the presence of gas or liquid, which prevents the oxidation of the metal. The melted metal may then be removed by agitation or other suitable means. The patentee proposes for the purpose a centrifugal machine, drawings of which are given in the specification. Seven claims are made.—T. L. B.

Improvements in the Manufacture of Sodium and Potassium. W. White, Cheshunt. Eng. Pat. 13,125, September 11, 1888. 4d.

IN order to avoid the well-known difficulty of obtaining a sufficiently intimate mixture of the sodium salt (carbonate or hydrate for example) and the reducing agent (some form of carbon) hitherto existing on account of the fusibility of the one and the buoyancy of the other, the patentee substitutes uncrushed charcoal for the powder usually employed, allows it to absorb within its pores the greatest quantity of sodium carbonate or hydrate in a molten condition it can take up, and then heats it in a retort and condenses the resulting sodium vapour in the ordinary way. It is claimed that a comparatively low temperature suffices for the reduction, and that the process is also applicable to potassium and to alloys of the two common alkali metals.—B. B.

The Manufacture of Plates and other Articles from an Alloy or Alloys of Copper and Nickel by Rolling at a Red Heat. Sir H. H. Vivian, Swansea. Eng. Pat. 13,358, September 15, 1888. 4d.

ALLOYS are made containing from one-tenth to 10 per cent. of nickel, the remainder consisting of pure copper. The two metals are melted together, cast into ingots, annealed and rolled at a red heat just as copper is rolled.—E. E. B.

Improvements in the Extraction of Copper from Copper Ores. H. Doetsch, Huelva, Spain. Eng. Pat. 13,359, September 15, 1888. 4d.

PERSULFATES of iron are obtained by dissolving natural iron oxides in sulphuric or hydrochloric acid. The patentee mixes with the ground oxides the equivalent quantities of the mineral acids, preferably strong sulphuric acid heated to 100° to 150° F. The persulphate is dissolved in water to about a one per cent. solution and then poured over copper ore. The copper is thus got into solution, from which it is precipitated by means of metallic iron.—T. L. B.

Improvements in Alloys. H. Eckhardt, Dortmund, Germany. Eng. Pat. 13,742, September 24, 1888. 4d.

CHROME iron ore and Bessemer slag of specified composition are smelted together with coal, or the chrome iron ore and slag are made into briquettes with tar and smelted in a blast furnace. The alloy thus produced contains 50 per cent. of chromium, 20 of manganese, and 20 of iron. If an alloy without manganese be required, powdered glass should be substituted for the slag.—E. E. B.

Improvements in and relating to the Manufacture of Steel and Iron. H. J. Smith, Newmans. Eng. Pat. 13,843, September 25, 1888. 6d.

To prevent red-shortness soda lime (or potash lime) is added to the iron in place of spiegeleisen or any other compound of manganese, preferably at the same stage in the manufacture at which it is customary to add the manganese.—E. E. B.

Improvements in the Manufacture of Alloys of Steel and Nickel. H. Schneider, Le Creusot, France. Eng. Pat. 14,150, October 2, 1888. 6d.

NICKEL is melted with iron or steel, care being taken to prevent oxidation of the nickel at this stage by covering it with anthracite during the fusion. More iron is subsequently added, and the operation conducted as in the manufacture of ordinary steel. Oxidation is prevented by means of a layer of slag or cinder and precautions must be taken to avoid red-shortness in the metal before the introduction of the ferro-manganese. The steel thus produced is specially suitable for the manufacture of ordnance, armour-plates, gun-barrels, &c. for military use.—E. E. B.

Improvements in and relating to the Extraction of Gold from Refractory and other Ores, and in Apparatus employed therein. J. Greenwood, London. Eng. Pat. 14,240, October 3, 1888. 8d.

THE powdered (and, if necessary, roasted) ore is charged into a chlorinator, and a solution of chlorine is then pumped in until a pressure of 80 to 100 lb. per square inch is obtained. All air is preferably expelled. After the apparatus has been revolved for some time the mixture is filtered through asbestos cloth in a shallow wooden apparatus, cone-shaped underneath, and the ore washed by means of a current of water introduced from beneath. The solution of gold chloride is then run into an electrolytic cell, the gold is therein deposited, and the chlorine liberated passed into water, the solution thus formed being used again as already indicated. Five claims are made. Drawings of the apparatus are given in the specification.—T. L. B.

Improvements in Apparatus employed in Coating Metal Plates or Sheets with Tin, Terne, or Lead. E. Brazier, Bilston, and J. Thompson, Wolverhampton. Eng. Pat. 14,807, October 15, 1888. 8d.

THIS is an apparatus by means of which the separate wash pot and grease pot are dispensed with, and the whole process reduced to one operation. It consists of a shallow dish in which the metal is melted, suspended in a larger pot filled with grease, to which is affixed the usual rolls, guides, &c. The sheets are pushed first through the grease, then the coating metal, and finally through the grease again, and are delivered by the rolls. Drawings are given. The advantages are: a minimum quantity of coating metal can be used, as its temperature is maintained by the body of grease in which it is suspended; the metal cannot be overheated; and any loss thereby is prevented.—A. W.

Improvements in and relating to the Manufacture of Steel and Iron. H. J. Smith, Newmains. Eng. Pat. 16,061, November 6, 1888. 4d.

THE object is to dispense with the use of spiegeleisen or ferro-manganese in the well-known oxidation processes, by subjecting the blown metal to the action of a mixture of sodium or potassium hydrate or carbonate and magnesia, or other alkaline earth, &c. The mixture may also contain metallic oxides, iron, or other metallic substances. The above materials remove the oxide of iron from the blown metal and are also said to diminish the percentage of carbon.

—A. W.

Improvements in and relating to the Extraction of Zinc from its Ores. H. A. Hunnicke, St. Louis, U.S.A. Eng. Pat. 18,024, December 10, 1888. 8d.

THE oxide ore and flux are heated to the reducing temperature before mixing with the fuel, which latter is also similarly pre-heated. The whole is then mixed in the reduction chamber, which is kept at a high temperature, and wherein the zinc vapours are produced. The superheated vapours and gases are then cooled as rapidly as possible in the condenser, the object being to minimise the period of existence of that stage during cooling in which the zinc reacts on the carbonic acid with the re-formation of oxide. This may also be accomplished by getting rid of the carbonic acid by passing the vapours, &c. through heated charcoal, with the result that the products consist only of carbon monoxide and zinc vapour. Drawings of a desirable plant are given.—A. W.

A New or Improved Metallic Alloy. F. Ellis, Harborne. Eng. Pat. 3109, February 21, 1889. 4d.

THE alloy consists of copper, 87 parts by weight; zinc, $6\frac{1}{2}$ parts; tin, 4 parts; arsenic, 2 parts; and phosphorus, $\frac{1}{2}$ part. The copper is first melted, and the zinc, tin, arsenic, and finally phosphorus added. The metal obtained is free from porosity, very ductile and elastic, slightly liable to tarnish, and retains a good polish. It is recommended for use in jewellery, ornaments, electro-work, metallic pens, bells, gongs, and shaft bearings.—A. W.

Improvements in or relating to the Coating of Metals. A. J. Boulton, London. From W. G. Clark, Hergott Springs, South Australia. Eng. Pat. 3149, February 21, 1889. 4d.

THE iron or steel is heated to a welding heat, coated with a flux and dipped into molten copper, whereby it becomes covered with a skin of the latter metal. The flux used is a local native earth, and is composed of silicious sand, oxides of iron and aluminium, and carbonate of lime, but the proportions are not given. Two sheets of copper, or a sheet of copper and one of iron, can be welded together by the aid of this flux.—A. W.

An Improved Metallic Alloy for Syphon Heads and other Objects, and for Tinning Purposes in General. D. J. Reisz, M. Berkovits, and J. Biehler, Budapest, Hungary. Eng. Pat. 3916, March 6, 1889. 4d.

THREE to five parts of nickel are heated to redness, when 10 parts of molten tin are added. Complete amalgamation takes place in about half an hour, and this alloy is then thoroughly stirred up with 990 parts of molten tin. The alloy thus obtained is compact, strong, and has the colour of nickel.—E. E. B.

Improvements in the Method of Purifying Quicksilver. P. Schroedter and A. Schroedter, Berlin, Germany. Eng. Pat. 5980, April 8, 1889. 6d.

THE mercury to be purified is filtered through cane or any dry non-resinous wood or stem of fibrous structure. A typical apparatus consists merely of a glass funnel joined at the end of its stem by a rubber ring to a piece of cane

about 12 cm. long and 1 cm. in diameter, on the top of which a plug of cotton-wool freed from oily matter is placed.—B. B.

Improvements in and Means or Apparatus for the Extraction of Metals from Metallic Ores or Matters containing Metals. N. Lébedeff, St. Petersburg, Russia. Eng. Pat. 7353, May 2, 1889. 8d.

THE natural ores, or combinations resulting from metallurgical operations (such as slags), and containing the oxidised metals, are melted in suitable appliances, such as crucibles or reverberatory furnaces, and a reducing gas is forced through the mass when in a state of fusion. To impart sufficient fluidity for the convenient injection of the reducing gas, it may be necessary to add a flux, the nature of which must be determined according to the ore under treatment. When the metal is reduced by the action of the gases, the slag and metal may be run out and treated as desired. The apparatus proposed consists essentially of two reverberatory furnaces placed one on each side of a vertical shaft. The ore is placed in the shaft, and is thus roasted before reaching the furnaces. The reducing gases are introduced by suitable tubes or inlets through the roof of the furnace.—T. L. B.

Improvements relating to the Welding, Soldering, or Brazing of Metals, and to Apparatus therefor. H. H. Lake, London. From E. Thomson, Massachusetts, U.S.A. Eng. Pat. 8038, May 14, 1889. 11d.

THIS specification does not admit of a suitable abstract. It is full of detail of the different methods and plans of the patentee for the various applications of electric soldering, brazing, &c. There are 50 drawings given.—A. W.

An Improved Flux for Coating Iron or Steel with Copper, and for Welding Copper. H. H. Chandler, Lanra, South Australia. Eng. Pat. 9187, June 3, 1889. 4d.

THE flux is composed of carbonate and sulphate of lime in a state of fine subdivision, either separate or mixed together.—E. E. B.

Improvements in the Treatment of Auriferous and Argentiferous Materials, and in Apparatus therefor. A. W. Lockwood, Auckland, New Zealand, and H. Chappel, Sydney, New South Wales. Eng. Pat. 9476, June 7, 1889. 6d.

THE ores, broken to small gauge, are roasted in retorts exactly resembling gas retorts. A perforated pipe runs along the bottom of each retort, whereby steam, superheated steam, or carburetted hydrogen may be passed. In the process sulphur, arsenic, and base metals are carried off and conveyed to condensing chambers. The roasted ore is afterwards ground and amalgamated as usual.—T. L. B.

Improvements in Joining Pieces or Articles of Metal Foil or Thin Metal together, or to other Pieces or Articles of Metal. J. Y. Johnson, London. From L. H. Rogers, New York, U.S.A. Eng. Pat. 11,734, July 23, 1889. 8d.

THE idea is to press the two sheets or foils together up to the line along which it is desired to join them and leaving the remainder free from pressure. The excess is then cut off, and the two freshly exposed edges fused together by the aid of a soldering iron. Two pieces of tin foil can in this way be joined together without a flux, but when tin foil is joined to some other metal a flux such as sal-ammoniac is preferred. The two acts of removing the excess and fusing the surfaces may be conducted in one operation and by the same tool. Drawings are given.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Bichromate Batteries for Domestic Lighting. Dingl. Polyt. J. 272, 561—564.

SOME of the recent devices for increasing the applicability of double and single fluid bichromate batteries for domestic lighting, are described. Such are *Mareschal's* plan for raising and lowering the zines in a single fluid battery which can be operated electrically from a distance, and the mercury cup used by *Radiquet* for two-fluid batteries, in which the zinc of each cell stands, and is thus kept thoroughly amalgamated; to the latter also is due a syphon which can be started without sucking and its attendant risk; the limb of the syphon, which is in the liquid it is desired to draw off, is surrounded by a wider glass tube closed at the bottom save for a hole smaller than the bore of the syphon itself; to the upper end of this outer tube is attached a flexible tube, on blowing through which the liquid in the annular space between the two tubes is depressed, and most of it choosing the easier path, is driven up into the syphon instead of through the small hole at the bottom of the wider tube.

Another arrangement for keeping the zinc amalgamated, described in *Le Génie Civil*, 1889, 107, and capable of utilising zinc scrap, consists in enclosing the zinc in a copper basket which is connected by two perforated copper rods with a porcelain capsule containing mercury which already contains a little zinc in solution, and which distributes itself over both copper and zinc, forming a protective coating, permanent with any ordinary output of current from the cell.

E. Landmann has arrived at the following conclusions with regard to single fluid bichromate cells:

- (1.) Such cells, especially if provided with some arrangement for regulating the area of the immersed portion of the positive plate, are capable of yielding a powerful current for a considerable time.
- (2.) It is essential to renew the spent fluid close to the plates; with a large volume of the exciting liquid, e.g., 6 litres, in a deep cell in which the active surface of the zinc is about 1 sq. dm., no alteration of the area of the immersed surface is necessary for about two hours.
- (3.) From their high E.M.F. and small internal resistance these batteries are well adapted for lighting glow lamps in parallel.
- (4.) In the case of retort-carbon the resistance and specific volume increase with the hardness and fineness of texture. The softer and more porous kinds, and those with a high specific gravity, give a higher E.M.F. and are less readily polarised. The use of artificial carbon plates is not advisable.
- (5.) Zinc as pure as possible, free from iron and carbon (compare Chem. News, 60, 95), should be used to avoid local action.
- (6.) Sodium bichromate is in every way preferable to the potassium salt, and chromic acid to either, as no crystals of chrome alum form, but its price is against it.—B. B.

PATENTS.

Improvements in and connected with the Manufacture of Iron. A. G. Greenway, West Derby. Eng. Pat. 6326, April 28, 1888. 8d.

An electric current is passed through cast iron in a molten state through which air is also forced, the object being to produce iron of greater strength than has hitherto been possible. Drawings accompany the specification.—E. E. B.

Improvements in the Means of Preparing Metallic Surfaces for the Reception of Non-adhesive Electro-Deposits in the Form of Tubes, Cylinders, Pans, and like Metal Wares. F. E. and A. S. Elmore, Cockermouth. Eng. Pat. 12,264, August 25, 1888. 6d.

The metal surfaces—properly cleaned and prepared—are coated with lead or a lead alloy by dipping in a bath of molten lead or alloy. Where necessary, as with cast iron, a coating of tin or a tin alloy is first applied and followed

by one or more coatings of the first-mentioned metal or alloy. Such a coating protects the original metal surface from the action of the bath and fills up all pinholes, &c.; the deposit of other metals upon it by electrolysis is, moreover, non-adhesive. When the metal surface or mould is composed of several parts, the coating is made to fill all interstices at the junctions.—E. T.

Improvements in Galvanic Batteries. A. Schanschlied, London. Eng. Pat. 12,290, August 25, 1888. 8d.

THE improvements are in methods of emptying and filling battery cells. In one method, each battery cell is provided with a second cell or annex, with which it communicates by a small hole near the bottom. Each annex communicates in a similar way with that on either side of it. These holes are large enough to keep the cells supplied with new liquor, but are too small to allow much electricity to flow. The annexes are supplied from a tank in which the level is kept constant by a ball-cock. The spent liquor, which is of low density, leaves the cell by an overflow pipe, and each cell has an opening at the bottom for emptying it.

In another method the cells are placed at successive lower levels, and the liquor flows from the top of one to the bottom of the next. In a third method, each cell is connected to its neighbour by a flexible tube, inserted near the bottom of each. If the bend of the tube be held above the level of the liquid in the cells, air enters by a small valve, and the columns of liquid on the two sides fall to the level of the liquid in the cells, which are thus insulated from one another. On lowering the bend, communication is again established and all the cells can be emptied or filled simultaneously.

—E. T.

Improvements in the Reduction of Zinc Oxides. C. A. Burghardt, Manchester. Eng. Pat. 13,182, September 12, 1888. 4d.

THIS is an improvement on Eng. Pat. 9886 of 1888 (this Journal, 1889, 551 and 624), for obtaining pure zinc by the electrolysis of an alkaline zincate solution. The improvement consists in preparing the zincate by adding the roasted ore, or oxide of zinc, to melted caustic potash or soda. The fused mixture is well agitated and afterwards dissolved in water.—E. T.

Improvements in the Construction of Secondary Batteries. S. A. Varley, London. Eng. Pat. 13,102, September 17, 1888. 8d.

ALTERNATE sheets of thin lead and canvas are enclosed in a strong vessel and raised to a temperature of about 400° F. The vessel is then exhausted of air and melted lead run in so as to completely fill it. Pressure is then applied by a screwed cylinder passing through the cover. The temperature is then raised to the melting-point of the contents, which unite more perfectly; at the same time the canvas chars and the gas evolved is allowed to expand by partially unscrewing the cylinder. The whole is then allowed to cool slowly, when the lead crystallises in small crystals, this operation having been facilitated by the charred material and gas rendering the mass porous.

The block thus obtained may be sawn up into plates and formed by Planté's process. Oxide of lead may be introduced with the canvas, which may itself be replaced by other materials.—E. T.

Improvements in or relating to Cases for Electrical Batteries or Cells. G. B. Satterlee, New York, U.S.A. Eng. Pat. 13,615, September 20, 1888. 8d.

THE invention applies to a method of hermetically sealing the containing cells of small portable batteries, such as are placed in gun-stocks. The top is closed by a tightly-fitting plug or stopper, with a head of rather less diameter than that of the outside of the case. Under this head, between it and the case, one or more rings of pure soft india-rubber are compressed by a ferrule screwing on the outside of the case and provided at the top with an inturned flange which

forces the stopper downwards. Grooves or channels may be turned in either the case or the stopper to grip the india-rubber better, and luting may be employed in addition if desired.—E. T.

Means for Producing suitable Acid or Salt Solutions for Feeding Electric Batteries. S. Eloesser, Berlin, Germany. Eng. Pat. 13,717, September 22, 1888. 8d.

WATER entering at the bottom of a mixing vessel is met by acid descending through a vertical tube from a second vessel placed above, the supply of both being regulated by suitable cocks. The mixture flows out near the top of the first vessel, and may, if desired, be more thoroughly mixed by passing through a third vessel containing broken coke or pumice stone. It finally trickles into the cells of the battery from a distributing pipe placed above them. The spent battery liquor passes from the bottom of the cell to a trough at the side, whence it can flow away. In another arrangement, the first mixing vessel is replaced by a T-tube, the acid entering by the vertical arm, the water by one horizontal one, and the mixture leaving by the other.

When a solid salt is employed it is contained in a vessel which is partly immersed in the mixing vessel. The immersed portion is perforated to allow the salt to dissolve.—E. T.

Improvements in Copper Amalgamating Plates. R. I. Atcherley and A. E. Sarti, London. Eng. Pat. 15,172, October 22, 1888. 4d.

To increase the amalgamating surface of plates used for the extracting of gold, and to render it more sensitive, a granular deposit of copper is effected electrolytically. This is then coated electrolytically with silver and the whole amalgamated.—B. T.

Improvements in Electric Batteries. P. Schoop, Oerlikon, Switzerland. Eng. Pat. 15,626, October 30, 1888. 8d.

THE sides and bottom of the containing case are provided with grooved ribs or fillets, resembling those used in boxes for storing photographic plates, microscopic slides, &c.; the electrodes slide into these grooves. One set of electrodes—the negatives, say—are provided with feet which are connected by lead strips passing out of the cell. The other set of electrodes are similarly connected, by lugs, to lead strips above the surface of the electrolyte. Or the current may enter at centres of one set of plates and leave at the circumferences of the other set.—E. T.

A New or Improved Method of Treating the Effluent Waters from Mines or other Waters holding Metals in Solution. M. Yglesias, London. Eng. Pat. 15,708, October 31, 1888. 4d.

THE waters are used as the electrolyte of a voltaic cell, with suitable electrodes, such as iron and carbon, a current of electricity being produced with deposition of the metal. Manganese, iron pyrites, slag, &c. as waste products, may be coated with graphite and used as the carbon electrode.—E. T.

Improvements in the Charging of Secondary Electric Batteries from Primary Batteries, and Apparatus for that Purpose. E. Tyer, London. Eng. Pat. 16,140, November 7, 1888. 8d.

THE secondary cells are divided into two or more groups, the terminals of which are connected to a suitable series of mercury cups. A commutator driven by clockwork is connected with the primary, and opens and closes the circuit between the primary and each group of secondary at regular intervals, giving the primary intervals of repose, which help to keep its plates from polarising excessively.—B. T.

Improvements in the Production of Pure Zinc. C. A. Burghardt, Manchester. Eng. Pat. 18,440, December 18, 1888. 4d.

IMPURE zinc is employed as anode in an electrolytic cell, the deposit of pure zinc being received on a suitable cathode. Zincate of sodium or potassium is used as electrolyte, and may be obtained by charging the cell with caustic alkali, and passing a current of electricity until pure zinc is deposited.—E. T.

Improvements in the Reduction of Zinc and Tin from their Ores. C. A. Burghardt, Manchester. Eng. Pat. 659, January 14, 1889. 6d.

FROM three to seven per cent. of carbonaceous material, such as powdered coal or charcoal, is mixed with the crushed and roasted zinc or tin ore, and the mixture is passed into a heated pot or vessel containing a fused mass of caustic soda or potash. The contents of the pot are stirred and kept hot until gases, chiefly carbon monoxide and dioxide, are no longer evolved, whereupon the mass is poured out, allowed to cool, and treated with water to dissolve out the soluble part. This solution is then subjected to the action of an electric current, and the metal is deposited upon the cathode. The caustic alkali may be obtained from the resulting liquid, and used for a further treatment of ore.—B. T.

Improvements in Primary and Secondary Transportable Galvanic Dry Elements. C. Smith, London. From W. L. F. Helleeson, Copenhagen, Denmark. Eng. Pat. 2297, February 8, 1889. 6d.

A DOUBLE containing case is used, the space between the two cells being filled with a material capable of absorbing moisture, such as sawdust, &c. Any gases generated pass through a plaster of Paris stopper near the top of the inner cell to perforations in its side walls, and are dried by the absorbent material, and thus rendered less harmful to the fittings of the battery. The electrolyte is made solid by the use of some such material as gum tragacanth, which by its sticky nature will always adhere to the electrodes, in spite of changes in the form or size of the latter, the materials ordinarily employed not being suitable when the cell is not hermetically sealed. The inner cell is closed in above the plaster of Paris by a layer of pitch or other suitable material.—E. T.

Improvements in Secondary Batteries. C. B. Askew and J. K. Pumpelly, Chicago, U.S.A. Eng. Pat. 7215, April 30, 1889. 8d.

To prevent any disintegration of the active material, one or both of the faces of each plate is covered by an insulating porous material, such as asbestos. Between the insulating coverings of contiguous plates are parallel ribs, formed either on the coatings or furnished by a separate frame. These ribs leave channels in which the liquid can circulate. To connect the plates—which are shown horizontal in the specification's drawings—each anode is furnished on one side with a lug, so thickened as to fill the space between the anodes immediately above and below. These lugs are bored, and all held firmly pressed together by a rod passing through the holes. The rod is smaller than the holes, and after being placed in position is protected from the electrolyte by pouring in melted lead to fill up the space round it. The cathodes are similarly connected on the other side of the cell.—E. T.

An Improved Process for the Electrolytic Separation of Aluminium, Aluminium Alloys, and Magnesium from Solutions of their Salts. G. Nahsen, Hanover, Germany. Eng. Pat. 8552, May 23, 1889, 4d.

THE inventor states that the production of "hydrate of metallic oxide" in all attempts to electrolyse aqueous or alcoholic solutions of aluminium or magnesium salts, is due to the fact that these metals decompose water at temperatures of 80° C. or less, and that when produced in the nascent

state by electrolysis (during which operation heat is evolved) this decomposition goes on at a much lower temperature. He has found, however, that below 4° C. all the aluminium is obtained as metal, and that hydrogen ceases to be evolved as a secondary reaction. His improvement, therefore, consists in cooling the electrolyte, especially in the neighbourhood of the cathode, by any suitable means, such as worms through which brine or salt lye circulate at a low temperature. Special means are taken to keep the solutions highly and equally concentrated. The positive and negative electrodes used are carbon and aluminium respectively.

—E. T.

Improvements in Secondary Batteries or Accumulators. T. Harris and H. F. de B. Cameron, Detroit, U.S.A. Eng. Pat. 8855, May 28, 1889. 6d.

THE plates of the battery consist of lead in which holes have been punched and tapped, so as to better retain the active material. The plates are held together by transverse rods of vulcanite with vulcanite washers of suitable thickness to act as distance pieces, and the whole rests upon a plate of india-rubber provided with bosses in order to reduce the jarring attendant upon transportation.—B. T.

An Improved Dry Galvanic Battery. D. J. Arnold and H. B. Coryell, Omaha, U.S.A. Eng. Pat. 9153, June 3, 1889. 6d.

THE containing case is of zinc and forms the positive element. The negative element is made up of round carbons, bunched together, and clamped at the top. Litharge, zinc chloride, ammonium chloride, oxide of mercury, and a body-former such as plaster of Paris, are mixed with water, and poured in a semi-fluid condition into the space between the carbons and the zinc containing cell, and allowed to set. The cell is closed hermetically by a layer of pitch or asphaltum.—E. T.

Improvements in and relating to Incandescent Electric Lamps. H. H. Lake, London. From S. F. Van Choate, Boston, U.S.A. Eng. Pat. 9576, June 8, 1889. 11d.

THE inventor describes a lamp holder and lamp cap, features of which are that the shade or reflector is held by a flange on the base of the lamp cap and is therefore secured by the act of placing the lamp in position, while the lamp itself is held by its wires being secured in sockets on the lamp holder. Two methods of sealing the tops of lamps are described, in one of which, a metal cap bearing the wires and filament is cemented on the open end of the lamp; while in the other method, the wires are sealed into a cup-shaped glass stem, which fits closely the open cylindrical end of the lamp, and is sealed thereto, mouth upwards, by fusion of the glass. The latter lamp fits at once, without any cap into the inventor's lamp holder. Lastly, the inventor describes a switch to be attached to each lamp, and provided, to reduce sparking, with a resistance coil common to all the lamps in the installation, and which is substituted for each lamp in the act of turning it off.—E. T.

Improvements in the Electrolytic Production of Hypochlorite of Sodium. E. M. H. Andreoli, London. Eng. Pat. 10,889, July 5, 1889. 6d.

TO increase the yield of the hypochlorite from chloride of sodium and to minimise the reducing action of the nascent hydrogen, the cathodes are made of much less area than the anodes and an oxidising material such as manganese dioxide is introduced into the bath in a retaining network placed between the anodes and cathodes. The anodes are made of carbon or manganese dioxide plates, and the cathodes of iron in the form of a gauze or trellis.—B. T.

Improvements in Storage Batteries. W. P. Thompson, Liverpool. From F. H. Alexander, Hyde Park, Mass., U.S.A. Eng. Pat. 11,044, July 9, 1889. 6d.

THE object of this invention is to construct a battery of high electro-motive force in a small space. Consecutive lead plates are separated from each other by a rubber packing going round the sides and bottom, and thus dividing the space between each pair of plates into a water-tight cell. These cells are filled with the electrolyte and charged in series, one side of each plate becoming positive and the other negative—the number of cells in series being always one less than the number of plates.—E. T.

Improvement in Insulation for Electric Conductors. C. T. Snedeker, St. Louis, Missouri, U.S.A. Eng. Pat. 11,067, July 9, 1889. 4d.

THE conductor is first coated with liquid shellac, and while this is still wet, a fibrous material, such as jute or silk, which has been well saturated in alum is served round it. A coat of a suitable liquid glue is then applied, and while the glue is still damp it is dusted with the following composition: four parts powdered glass, one part powdered alum, one part powdered asbestos. Next a fibrous material which has been well saturated with a paste of linseed oil, litharge, white lead, ground asbestos, and alum, is served round, and the whole is covered with more alum-treated fibrous material. When dry, this coating is treated with a varnish gum dissolved in linseed oil, and into this is pressed a thin coat of asbestos fibre. Finally, when hard and dry, a coat of suitable varnish is applied.—B. T.

An Improved Method and Apparatus for Connecting Carbon Filaments to Metallic Conductors and for similar Purposes. H. H. Lake, London. From H. Kemp, Lynn, U.S.A. Eng. Pat. 11,071, July 9, 1889. 8d.

JOINTS between metallic conductors and carbon filaments are generally weak mechanically on account of the carbon deposit obtained in a hydrocarbon chiefly falling upon the filament itself. To obviate this, the inventor flattens out the conductor, pierces a hole through it, passes the filament through the hole, and then by sending an electric current through the filament, immersed in a hydrocarbon, builds up a mass of carbon about the metal in the form of a rivet, making good electrical contact and a strong mechanical joint. Various methods of jointing in a similar manner are described, together with apparatus for holding the filament and conductors.—B. T.

Improved Grids or Supporting Frames of Electric Accumulators. E. Correns, Berlin, Germany. Eng. Pat. 11,328, July 15, 1889. 6d.

EACH plate is made up of two grids superposed, each having tapering square holes. The grids are put together so that the centre of each hole on one plate is opposite the boundaries of four holes on the other. In the process of manufacture, the wedge shape is given to the holes, after the superposition of the plates, by dies which pass through the perforations in the upper plate and give the required shape to the boundaries of the holes in the lower.—E. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On Palm-nut Oil and its Composition. E. Valenta. Zeits. f. angew. Chem. 1889, 334—337.

THE amount of free acid in palm-nut oil was found to vary, according to its origin and age, between 7 and 58 per cent., and the melting point between 23° and 28°. Shadler has stated in his "Technologie der Fette," that palm-nut oil consists only of palmitin and olein, but this is inaccurate. A mixture of several samples of palm-nut oil from various sources was saponified, the soap acidified, and the fatty acids liberated distilled in a current of steam. The fatty acids in the distillate were submitted to fractional distillation, and at 185° to 200°, a fatty acid passed over which was found to be caproic acid. The residue in the flask was too small for identification. The fatty acids in the residue from the first distillation were submitted to fractional distillation at a pressure of 100 mm. The different distillates were purified by crystallisation from alcohol and fractional precipitation

with acetate of barium or of lead. In this manner acids of constant melting point were separated which were identified from their chemical and physical properties as caproic, caprylic, capric, lauric, myristic, palmitic, and oleic acids, the chief portion consisting of lauric acid.—E. E. B.

Amount of Free Fatty Acids in Oils and Fats. H. Noerdlinger. Zeits. Anal. Chem. 28, 183—187.

THE oils and fats examined were dissolved in a carefully neutralised mixture of alcohol and ether, containing phenolphthalein, and titrated with decinormal potash solution. The acidity found was calculated as oleic acid according to Salkowski's example (this Journal, 1888, 37). Different qualities of the various oils and fats were examined, namely pressed salad oils, common pressed qualities as used for technical purposes, and crude extracted oils. The extracted oils were obtained in the laboratory by the use of petroleum spirit in preference to ether. Except where otherwise mentioned freshly prepared samples were used for the tests. The author's results are given below:—

	Percentage of Free Fatty Acid as found by		Average Percentage of Free Fatty Acid in		
	Salkowski.	v. Rechenberg.	Salad Oil.	Common Oil.	Crude Oil.
Liquid oils:—					
Rape.....	4.28	6.64	1.19	2.88	0.93
Olive.....	1.17	2.25	1.66	12.97 (purity doubtful)
Poppy.....	2.29	2.09	1.92	15.37	4.72
Earth-nut.....	1.66	1.94	6.52	4.02
Sesame.....	1.97	17.94	4.89
Cotton-seed	0.29	0.15	0.46
Mustard	0.85
Castor	9.28	2.78
Linseed	3.45	1.74	1.57
Candle nut (sample about 3 years old).....	56.45
Solid oils and fats:—					
Palm-nut	13.33	6.91	8.49
Palm (old sample; method of extraction unknown)	50.82
Cocoa-nut.....	2.96	7.92	4.26
Illipe (from seeds of a species of <i>bassia</i> ; sample 3 years old).....	28.54
Niam (from <i>Lophira alata</i> Banks.)	24.56
Bicuhyba (from <i>Myristica bicuhyba</i> ; sample 3 years old).....	18.55
Japan wax (method of extraction unknown)	9.25

The quantity of free fatty acid present in vegetable oils varies between pretty wide limits. In the case of the cotton-seed oil tested, the small amount of free acid found is explained by the fact that the oil was refined by means of caustic alkali, which almost entirely removed the fatty acid. The average percentage of acidity of the salad oils is 1.74. This fact may, in certain circumstances, lead to the detection of an adulteration with cotton-seed oil, as it may also be frequently of service in indicating the quality of a salad oil, which is most pleasant to the taste when only a small amount of free acid is present, but is very insipid when quite free from acid.—E. B.

On the Fatty Acids of Drying Oils. K. Hazura. Monatsh. Chem. 10, 190—195.

A CONTINUATION of previous researches (this Journal 1888, 680—681). The present paper deals with the con-

stitution of *sunflower oil*, which the author finds to consist of a mixture of the glycerides of linoleic acid, $C_{18}H_{32}O_2$, and of oleic acid, $C_{18}H_{34}O_2$. As the latter glyceride is present only in small quantity, sunflower oil would be a suitable material for the study of linoleic acid. The fatty acids were identified, through their products of oxidation, as obtained by the method previously employed by the author and described in the reference cited above.—G. H. B.

On the Oxidation of Unsaturated Fatty Acids with Potassium Permanganate. A. Grüssner and K. Hazura. Monatsh. Chem. 10, 196—199.

THIS paper treats of the oxidation of brassidinic and ricinelaidic acids. The employment of potassium permanganate for the oxidation of fatty acids has been described in previous communications. (Compare this Journal, 1888, 680 and 681.) Brassidinic acid, $C_{22}H_{42}O_2$, was obtained by

the action of nitrous acid on erucic acid, and yielded by oxidation a substance of the formula $C_{22}H_{42}O_2(OH)_2$, which the authors have named isodioxybehenic acid. It crystallises from dilute alcoholic solutions in microscopically small rhombic tables, melting at 98° – 99° C. Ricinelaïdic acid, $C_{18}H_{34}O_2(OH)_2$, yields by oxidation the substance $C_{16}H_{30}O_2(OH)_2$, termed β -isotrihydroxystearic acid. This substance crystallises from glacial acetic acid in long needles, and from benzol in rhombic prisms, melting at 114° – 115° C. Brassidinic and ricinelaïdic acids are thus found to comport themselves on oxidation like oleic, linoleic, linolenic, erucic, and the acids from castor oil, which were examined in previous researches.—G. H. B.

Observations on some Non-drying Oils. K. Hazura and A. Grüssner. *Monatsh. Chem.* **10**, 242–249.

THE authors have previously expressed the opinion that most of the non-drying oils contain, besides oleic acid, some other unsaturated acids, and for the purpose of differentiating the components of various oils they employ the method of oxidation with alkaline potassium permanganate. Earth-nut oil, examined by this method, yielded as oxidation products, sativinic acid, $C_{18}H_{32}O_2(OH)_4$, dioxyerucic acid, $C_{18}H_{34}O_2(OH)_2$, and probably also dioxy palmitic acid, $C_{16}H_{30}O_2(OH)_2$, from which it is inferred that the unsaturated fatty acids of earth-nut oil are linoleic acid, oleic acid, and probably hypogeic acid. In a similar manner it is shown that almond oil and sesame oil contain the glycerides of oleic and linoleic acids. Olive oil was examined by Oudemans's method and found to contain 13 per cent. of glycerides of saturated fatty acids and 87 per cent. of glycerides of unsaturated fatty acids.—G. H. B.

Composition of Solid Fats of Animal and of Vegetable Origin. R. Benedikt and K. Hazura. *Monatsh. Chem.* **10**, 353–356. (Compare this Journal 1888, 506–681.)

THE authors have investigated fats of the former class by means of their method of oxidation with alkaline permanganate, and the study of the products. The entire absence of sativic acid, the characteristic product of the oxidation of linoleic acid, proves the absence of the latter, and establishes a general distinction, in proximate composition, between the two classes of fats, those of vegetable origin invariably containing linoleic acid.—C. F. C.

PATENTS.

An Improved Method of Marking or Branding Transparent and other kinds of Soap, and a Machine for accomplishing the same. F. W. M. Bateman, London. Eng. Pat. 13,373, September 17, 1888. 8d.

SOAPS of all kinds are at present branded on the surface only, either by impressed or raised letters, which speedily disappear when in use. By this invention, opaque soaps are branded with the mark by perforating the cake with small holes right through. The method for marking transparent soaps is by the insertion in the centre of the cake, in a horizontal position, of a tablet of soap or other suitable material through which is perforated the desired brand or mark. Drawings are given of the machine used for accomplishing this.—B. H.

Improvements in and relating to the Purification of Glycerin. J. C. A. Brunner, Munich, Germany. Eng. Pat. 15,124, October 20, 1888. 4d.

CRUDE glycerin is heated with 8 per cent. of zinc sulphate, which may or may not have been roasted. When cool, 2.7 per cent. of lime is added, and the mixture filtered. Any lime in solution is removed by carbonic acid; traces of metals are precipitated with hydrogen sulphide, and the excess of this is removed by blowing in air.—E. J. B.

An Improved Soap Powder. H. C. Foulsham, Brondesbury. Eng. Pat. 15,558, October 29, 1888. 4d.

THE improved soap powder consists of 20 lb. soap, 12 lb. alkali, 10 lb. carbonate of soda, 70 lb. soda crystals, and 1 gallon of petroleum.—E. J. B.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

The Modifications of Cadmium Sulphide obtained in the Wet Way. N. v. Klobukow J. Prakt. Chem. **39**, 412–425.

IN preparing cadmium sulphide in the wet way several coloured products, the shade of which varies from bright yellow to dark reddish-brown according to the conditions employed, are obtained, and it was formerly thought that the variations in the colour and density of the precipitates was due to a difference in chemical composition.

Follenius (*Zeits. Anal. Chem.* **13**, 411) and Buchner (*Chem. Zeit.* **11**, 1087 and 1107; this Journal 1887, 665–666) have proved however that the compounds formed in aqueous solutions have the same chemical composition whatever the conditions of the experiment, so that the various precipitates are either physically isomeric or perhaps simply physical modifications of one and the same sulphide. Buchner found that two, and only two modifications of cadmium sulphide are obtained in the wet way, namely, a lemon-yellow α -modification and a specifically heavier vermilion β -modification which he considers to be a polymer $(CdS)_4$ or $(CdS)_6$ of the former. Both modifications are chemically identical and, according to Buchner, can be converted one into the other under the influence of heat or chemical agents. According to Zsigmondy (*Dingl. Polyt. J.* **266**, 364; this Journal, 1888, 122–123) the two modifications show the same behaviour towards heat even when they are dissolved in glass.

The author determined the specific gravity of various (slightly impure) samples of the α - and β -modifications, dried at 105° – 107° , and the results are given in a table. The specific gravity of the α -modification was found to be about 3.9, that of the β -modification about 4.5, so that the difference cannot be due simply to their having been prepared under different conditions, and shows clearly that the two substances are really polymeric. The α - is much more hygroscopic than the β -modification.

A crystallographic investigation showed that the modifications of cadmium sulphide obtained in the wet way may exist in at least two, perhaps even in three distinct crystalline forms. The α -modification is entirely crystalline, but the crystals are not well-defined. A vermilion sample of the β -modification showed crystals similar to, but smaller than, those of the α -modification; another vermilion sample seemed to consist of spherical aggregates. A bright orange-red sample consisted of large well-defined crystals, and differed from all others examined.

The α -modification can be gradually converted into the β -modification by rubbing or by pressure, but the β -modification is not changed by mechanical agents.

The conversion of the α - into the β -modification by rubbing can be effected with the most varied surfaces (agate, glass, porcelain, paper, asbestos, &c.), and either the slightly moist or the perfectly dry substance can be employed; the change is gradual, the colour passing through all the various shades and finally becoming vermilion, but the portions immediately in contact with the rubbing surface are bright red. The β -modification obtained in this way is identical with the pure β -modification prepared by Buchner. If the sample is very damp or made into a paste with water the conversion takes place extremely slowly and only with very energetic rubbing.

The conversion of the α - into the β -modification by pressure is readily effected by placing the air-dried substance in a steel mortar, covering it with a well-fitting stamp and giving the latter several powerful blows. The interior of the compact shining mass thus obtained is vermilion, but parts of the surface most exposed to the pressure have a rather darker shade.

The moist α -modification is also partially converted into the β -modification by the action of induction sparks and by nascent hydrogen, but a considerable proportion is reduced.—F. S. K.

PATENTS.

An Improved Enamel or Varnish for rendering Casks and analogous Articles Damp-proof, and for other useful Purposes. E. Hipwell and B. B. Hofmann, London. Eng. Pat. 13,007, September 8, 1888. 4d.

A "thick enamel" and an "enamel wash" are made. To produce the former, 1 lb. of white shellac is dissolved in two pints of absolute alcohol, and 1 lb. of the solution mixed with $1\frac{1}{2}$ lb. of methylated spirit. To $1\frac{1}{2}$ lb. of the mixture is added 2 lb. of "Creta Gallica or Alanin," continually stirring with a glass rod. The "enamel wash" is made by boiling 1 lb. of ground rice in 1 gal. of water for two hours, allowing to cool, adding while tepid 1 lb. of gelatin, and when cold $\frac{1}{4}$ lb. of salt, adding to $\frac{1}{2}$ gal. of this mixture 2 lb. of "Creta Gallica or Alanin," "dissolved" in 1 gal. of water, and incorporating $\frac{1}{4}$ pint of methylated spirit mixed with $\frac{1}{4}$ pint of water in which $\frac{1}{4}$ lb. of gum arabic or isinglass has been dissolved. Either composition is used, as circumstances may direct, and is applied with a brush.—B. B.

The Manufacture of a New or Improved Fabric, and its Application for the Making and Repairing of Boots and Shoes, and for other Purposes. R. Dick, Glasgow. Eng. Pat. 13,285, September 14, 1888. 1s. 1d.

THE inventor claims the manufacture of a waterproof material made by coating sheets of a suitable fabric with solution of india-rubber. Two or more sheets may be joined together. The material may be employed for a variety of purposes, such as insertion between sheets of leather, to form the soles of boots, waterproof coverings for saddles, covers for books, dressing cloth for hospitals, &c.

Complete drawings of the machinery used in the preparation of the material, and descriptive drawings of various manufactured articles, are given.—E. J. B.

A New or Improved Composition or Paint to be used for Coating and Preserving Metal, Wood, and other Substances and Materials. W. C. Nangle, London. Eng. Pat. 13,721, September 22, 1888. 4d.

FIFTY-SIX galls. of coal tar, pitch, or bitumen is boiled for an hour with "8 galls. of cow-dung," the latter strained off, and the filtrate boiled with "8 galls. of bark" for $2\frac{1}{2}$ hours. The tanning material is then strained off, "8 galls. of sulphur" and "6 galls. of rosin," and finally 70 lb. of gypsum added, the whole stirred and ground free from lumps, allowed to cool, and 26 galls. of turpentine mixed in. The resulting composition may be used for coating wood or metal to prevent corrosion and decay, the surface to be treated having been previously rubbed with chalk; it may also be employed for covering hot surfaces.—B. B.

Improvements in the Process of Cementing Asbestos. J. Dewrance and B. E. Church, London. Eng. Pat. 15,236, October 23, 1888. 4d.

THE chief expense in cementing asbestos with india-rubber arises from the waste of rubber solvent which has to be used to saturate the asbestos, to allow of its mixture with the solution of india-rubber. The patentees claim to have overcome the difficulty by using warm distilled water as the incorporating agent, either making an emulsion of it and the solution of india-rubber, and saturating the asbestos with this, or soaking the asbestos in water and then mixing it with the rubber solution, the principle underlying each method being the substitution of water for solvent naphtha as a saturating agent. Sulphur, plumbago, or litharge may be mixed in at this or a later stage, the bulk of the water squeezed out, the rest evaporated, together with the rubber solvent, and the mass vulcanised by any ordinary process.

The material may be mounded, rolled, or pressed into the form required, or the fibres may be separated and caulked into the grooves of cocks, in the manner described by one of the patentees in Eng. Pat. 4282 of 1883.—B. B.

An Improved Paint or Composition especially suitable for Coating Ships' Bottoms, and the Process of Manufacturing the same. J. Baynes, W. H. Doughty, and H. T. Greaves, Hull. Eng. Pat. 15,564, October 29, 1888. 4d.

FIFTY parts of copper scales are kept in contact with 17 parts of carbolic acid for several days in an air-tight vessel, until carbolate of copper has formed, when 21 parts of zinc oxide, 28 parts of "oxide of iron," 4 parts of red lead, 4 parts of "arsenic," and $5\frac{1}{2}$ parts of "boiled seed oil," are mixed in, and the whole passed through granite rollers. The mixture is transferred to a pan, and kept "near boiling heat" for two hours. Meanwhile, 7 parts of "shellac or other gums" are melted in a second pan, "the boiled seed oil" added, the mixture kept at a gentle heat for 30 minutes, 3 parts of spirits of turpentine added, and the whole run into the first pan. In a third pan 56 parts of "resin" are "dissolved," 2 parts of sugar of lead added, the mixture boiled gently for 30 minutes, 17 parts of turpentine added, and the whole run into the first pan, the contents of which is well stirred until the temperature falls to 70° F., when 36 parts of "mineral naphtha" are stirred in. In using this paint for iron or steel, it is necessary to cover the structure to be protected with a coat of priming composition containing "for its basis a metallic oxide electro positive (*sic*) to iron or steel," "to prevent actual contact between the iron and copper."—B. B.

An Improved Knife or Mechanical Contrivance for Cutting or Bleeding India-rubber Trees. C. Melhado, Upper Norwood. From H. B. de Blancaneaux, Belize, British Honduras. Eng. Pat. 15,604, October 30, 1888. 6d.

A STRONG knife with a curved blade, of which the cutting edge is convex, has bolted to it parallel to the blade close to the end remote from the handle, a piece of steel bent into the shape of a U or pot-hook, one side of which is sharpened to a cutting edge. By means of this grooves can readily be cut in the bark of india-rubber trees of a depth governed by the position of the second blade with respect to the first, a slot in which work a nut and bolt allowing of adjustment in this respect.—B. B.

Improvements in Dentists' and other Vulcanising Flasks. T. Wilson, Glasgow. Eng. Pat. 4360, March 13, 1889. 6d.

THE flasks are in halves bolted together by their lugs when in use; each half is in section a truncated cone, with its base at the plane of juncture. Viewed as a separate vessel, each half has a removable bottom which slides into position through a slot in the side and rests on a rim or ledge running partly round the bottom of the half flask on the inside. By means of this device, on separating the halves, the contents of each can be readily knocked out by tapping on the removable bottom, the process being facilitated by the conical shape of the flask.—B. B.

A New Composition for Waterproofing Textile Fabrics, and as a Paint for Wood and other Surfaces. E. S. Baldwin, Loughborough. From J. Smith, Marton, New Zealand. Eng. Pat. 10,858, July 5, 1889. 4d.

A COMPOSITION is made containing 56 lb. of white lead, 3 galls. of boiled linseed oil, 3 lb. of "patent dryers," 20 lb. of "whitening," 4 lb. of sulphate of lime, 3 oz. of alum, $1\frac{1}{4}$ lb. of glue, mixed in a manner varying with the "quality of the ingredients." The mixture can be applied to wood, iron, plaster, or other materials, as a paint, or spread over textile fabrics in one or more layers, preferably rolling the article treated between each application. It is said to be to a certain extent fire-proof.—B. B.

Improvements relating to the Treatment of Lead and other Fumes in the Manufacture of Pigments, and to Apparatus therefor. F. L. Bartlett, Portland, Maine, U.S.A. Eng. Pat. 11,405, July 16, 1889. 8d.

THE bulky character of lead fume and the dark colour due to the presence (according to the patentee) of cadmium, sele-

nium, vanadium, tellurium, "sulphur compounds, carbonaceous matter, and acids," which it possesses, hinder its use as a pigment, until it has been refined by sublimation or similar expensive processes. The method now proposed consists in heating it in an iron tube set horizontally in a furnace and containing a coreless screw concentric with the tube, and rotated in it by a shaft and pulley. The fume is fed in by a hopper at one end, and is carried slowly by the screw to the other, where it is discharged; on its way it meets a gentle current of air drawn in at one end and discharged at a point near the hopper at the other end, such current being obtained by the use of a hood fitting on the top of the furnace, and furnished with an exit pipe, thus inducing a slight draught. The result of this treatment is that the fume becomes dense and white and suitable for use as a pigment. In order to prevent the fume sticking to the screw and becoming partly converted into litharge, a rod is occasionally introduced and allowed to tumble round with the motion of the screw. Care must be taken to prevent more fume passing in through the hopper than is enough to form a thin even layer in the tube.

The screw is preferably made of cast iron, stayed by longitudinal rods, and has the form of a flat bar coiled lengthwise. It may be rotated in the tube as described above, or the tube may be rotated about it, without altering the principle of the apparatus or the nature of the product.

—B. B.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENTS.

Improvements in the Utilisation of Leather Waste. W. A. Burrows, London. Eng. Pat. 14,235, October 3, 1888. 6d.

THIS is an improvement of Eng. Pat. 11,880 of 1885 (this Journal, 1886, 329). The waste leather, after being disintegrated, is submitted to the action of an acid, such as oxalic, citric, tartaric or acetic, or of an alkali, such as soda, potash or ammonia. The leather flock is then mixed with a suitable proportion of fibrous material, such as spent tan, wood pulp, jute, oakum, &c. &c.

When the flock is to be used for the manufacture of hard articles, such as door-knobs or boot-heels, it is mixed with a solution of gelatin to which has been added some alum or other astringent. The mixture, while damp, may be moulded or otherwise formed, and when dry is perfectly hard. The leather flock may also be mixed with solution of various gums or resins in linseed or other oil, and after mixing, the product may be rolled into sheets or forced into moulds.

—B. H.

Means for Freeing Skins, Kips, and Hides from Lime, and for causing the same to Swell. J. Hauff, Feuerbach, Germany. Eng. Pat. 10,110, June 20, 1889. 1d.

IT has been found that cresotinic acid had too powerful an effect on very soft skins when used for neutralising the lime. Oxynaphthoic acid (hydroxynaphthoic acid), which is soluble in 20,000—30,000 parts of water, has been successfully tried. Salicylic acid, or a mixture of salicylic and cresotinic acids, can also be used for causing the hides to swell. "As cresotinic acids should be understood the carbonic acids from the three cresols, and as oxynaphthoic acids the carbonic acids from the naphthols."—B. H.

XV.—AGRICULTURE, MANURES, Etc.

Manurial Experiments in Hanover. Salfeld. Jour. f. Landw. 1889, 25—33.

THE experiments the results of which are given below were carried out on the old Eschland.

1. Winter rye, after unmanured buckwheat, grown on plots of 1 hectare each.

(a.) Unmanured produced 358 lb. (b.) Thomas phosphate powder produced 901 lb. (c.) Thomas phosphate powder and horn-meat produced 935 lb. (d.) Thomas phosphate and sulphate of ammonia produced 972 lb. (e.) Thomas phosphate and Chili saltpetre produced 1,008 lb. (f.) Bone-meal produced 1,027 lb. These various manures were applied in such quantities that 900 grms. of phosphoric acid and 222 grms. of nitrogen were supplied per hectare. The Thomas phosphate, horn-meat, and bone-meal were applied 11 days previous to sowing; the ammonium sulphate was drilled with the seed, and the sodium nitrate was top-dressed.

II. A series of experiments were made with a view to determine whether, in growing a crop of winter rye on the old Eschland, it would be an economy to use a nitrogenous manure in addition to the Thomas phosphate powder. The average of three unmanured plots was 5·033 kilos. of grain and 14·683 kilos. of straw. The average of four plots manured with Thomas phosphate was 7·382 kilos. of grain and 19·912 kilos. of straw. Four plots manured with Thomas phosphate powder and ammonium sulphate averaged 8·995 kilos. of grain and 22·35 kilos. of straw, and other four manured with Thomas phosphate and sodium nitrate averaged 13·532 kilos. of grain and 31·225 kilos. of straw. The manures were applied so that 180 lb. of phosphoric acid, 60 lb. of nitrogen, and 216 lb. of potash were present per hectare. Reckoning the grain and straw at the then prevailing prices, the gain in excess of the value of the unmanured plots of the other three was respectively 59·08 M., 59·28 M., and 167·25 M.

III. A series of experiments were made to test the manurial value of kainite and Thomas phosphate powder for buck-wheat and sporgel, the result being that while with both of these manures when used singly an increased crop was obtained, a very much better crop was produced by the application of the two together.—J. W. L.

Mineral Value of several Sea Coast Products. A. Mayer. Jour. f. Landw. 1889, 42—47.

	Moisture.	Organic Matter.	Nitrogen.	Potash.	Phosphoric Acid.	Calcium Carbonate in Ash.	Sodium Chloride.	Sand.	Total Ash.

—J. W. L.

Comparative Value of various Phosphates as Manures for the Cereals. J. Raulin. J. d'agric. pratique, 1889, 105—106.

FROM a series of experiments made with several finely-ground insoluble phosphates (phosphatic minerals) with superphosphate and precipitated phosphate, the author finds that the superphosphate and precipitated phosphate can be successfully replaced by mineral phosphate, when in the first year from five to six times the usual amount of phosphoric acid is employed. In these experiments, which were made on a soil rich in humus and lime, maize was grown in 1887, and wheat followed in 1888. The amounts of phosphoric acid in the first year were: In the case of superphosphate and precipitated phosphate 40 kilos. per

hectare; in the case of the finely-ground minerals 200 kilos. per hectare. In the following year all the plots received the same amounts, namely, 40 kilos. of phosphoric acid per hectare.

Comparative Experiments on the Manurial Value of Sodium Nitrate and Ammonium Sulphate. C. Rolland. J. d'agric. pratique, 1889, 423—426.

WHEAT was grown on three plots, one of which was left unmanured, whilst of the other two, one received ammonium sulphate, equivalent to 30 kilos. of nitrogen per hectare, the other sodium nitrate containing the same amount of nitrogen. The following table contains the principal results:—

Manure per Hectare.	Cost of Manure.	Produce per Hectare.		Increased Produce.		Value of Increased Produce.		Profit.
		Grain.	Straw.	Grain.	Straw.	Grain.	Straw.	
200 kilos. of sodium nitrate.....	M. 43'20	Kilos. 1,835	Kilos. 4,835	Kilos. 605	Kilos. 2,375	M. 135'20	M. 66'50	158'50
150 kilos. of ammonium sulphate.....	37'20	1,500	2,870	270	410	60'48	11'48	34'75
Unmanured	1,230	2,460

(1 hectare = 2·47 acres.)

—J. W. L.

The Effect of Common Salt on Vegetation. A. Stood. Landw. Vers. Stats. 36, 113—118.

THE damaging effect of salt on vegetation is most noticeable when the ground is so badly drained that the salt water remains about the roots of the plant, and also where, during the hot summer months, it rises towards the surface and there becomes concentrated. The author records two cases where in the lower parts of two fields there were ditches containing more or less salty water. In the neighbourhood of these both the grass and also the trees suffered, whereas on the higher ground away from the influence of the ditch, a luxuriant herbage prevailed.

The analyses of the soil taken from those parts of the fields near the salty ditch and away from the same, showed a very considerable excess of sodium and chlorine in the former over that of the latter. In the ash of the plants from the respective parts of the two fields, that of the diseased plants contained very considerable quantities of sodium and chlorine, whilst the ash of the healthy herbage contained comparatively but very little of these ingredients.—J. W. L.

PATENT.

A New or Improved Composition for Destroying Insects and Protecting Trees and the like therefrom. G. I. MacMunn, St. Mary Cray. Eng. Pat. 11,721, July 23, 1889, 4d.

ONE pint of "Oil Mentha Viridis (or oil of Spearmint)," 1 oz. of arsenious acid, and 7 oz. of carbolic acid are mixed with 1 cwt. of a mixture consisting of two parts of "resin oil," and one part of carbonate of lime. The viscid composition thus obtained can be smeared on the trunks of trees and stems of plants to prevent insect ravages.

—B. B.

XVI.—SUGAR, STARCH, GUM, Etc.

PATENTS.

Improvements in Means or Apparatus for Drying Slabs of Sugar, applicable for Heating and Cooling other Articles and for Analogous Operations. B. E. R. Newlands, London. Eng. Pat. 12,784, September 4, 1888. 8d.

ON two shafts arranged (preferably) vertically one above the other and parallel to each other are mounted sprocket wheels or drums, over which pass endless chains. Attached to these chains are a series of boxes made of perforated metal sheets, the outer end of each box being open, the inner end attached to the chains. The whole is so cased in that the sugar slabs or other articles, which are automatically fed into the boxes at one point of their circuit and discharged at another, are exposed during the time they are in the boxes to a current of hot air. The speed of the chains and of the carriers or boxes is so arranged that the time occupied by the passage of each block is just sufficient to effect the necessary desiccation. Drawings are given.—A. J. K.

Improvements in the Manufacture of Sugar and in Apparatus therefor. G. Adant, Molenbeck-St.-Jean, Belgium. Eng. Pat. 13,084, September 10, 1888. 8d.

THIS invention relates to the manufacture of sugar in slabs, flat cakes, or blocks. The details of the apparatus are such as can only be described intelligibly by reference to the drawings which are provided with the specification.

—A. J. K.

Improvements in the Treatment of Sugar Solutions. J. G. Lorrain, London. Eng. Pat. 13,595, September 20, 1888. 6d.

INSTEAD of concentrating sugar solutions in the ordinary way by evaporation, the water is resolved into its constituent gases by means of electrolysis.—A. J. K.

Improvements in Centrifugal Apparatus for Drying Sugar or other Granular Matters. D. Stewart, Glasgow. Eng. Pat. 13,655, September 21, 1888. 8d.

THE invention relates to centrifugal apparatus somewhat similar to that described in Eng. Pat. 6931 of 1884, and has for its object to improve and simplify the construction of such apparatus. The turbine or rotating basket is placed with its axis horizontal and has within it a hollow drum fixed on a central shaft, leaving an annular cylindrical space between it and the inner surface of the turbine. The moist sugar is supplied by a hopper into one end of the annular space and is gradually propelled along that space to the other end of the turbine by helical flanges or blades fixed on the outside of the inner hollow drum. The turbine and drum are driven at slightly different speeds, and the movement of the sugar through the turbine is due to this difference of speed, which can be regulated to the best advantage. "The inside of the wire-gauze surface of the turbine" is slightly taper, and the turbine and hollow drum can be so adjusted as to have the helical blades at the most convenient distance from the wire gauze. The shaft of the hollow drum passes through a tubular shaft on which the turbine is fixed, and the driving pulleys may both be fixed on their respective shafts at one and either end of the turbine or one at each end. The axis may be in any other position than horizontal, but the latter is preferred.

—A. J. K.

An Improved Apparatus for Producing White Sugar. C. Steffen, Vienna, Austria. Eng. Pat. 8622, May 24, 1889. 8d.

THE sugar mass is lixiviated in moulds with an aqueous solution of pure white sugar. The moulds are so arranged that they can be worked in battery, the slightly impure syrup from the first series passing on to the top of the second series, and so on. The final white syrup is driven out by compressed air.—A. J. K.

Improvements in Apparatus for the Manufacture of Sugar by Electricity. E. Maigrot and J. Sabates, Havana, Cuba. Eng. Pat. 9994, June 18, 1889. 8d.

THE treatment of the juice takes place in a series of troughs, each of which is divided by parchment paper or some other suitable material. The saccharine liquor is in the middle compartment and the outer compartments contain water to the same level. The positive pole of the dynamo is connected with carbon electrodes placed in the sugar liquor, whilst the negative pole is connected with carbon electrodes placed in the water in the two outer compartments. The action of the current decomposes the salts in solution, liberating the bases (potassium, sodium, magnesium, calcium, &c.) at the negative poles. In addition, it is claimed that the organic impurities are decomposed or rendered insoluble by the action of the current.—A. J. K.

XVII.—BREWING, WINES, SPIRITS, Etc.

Action of Maltose in presence of Diastase during Saccharification. L. Lindet. Bull. Soc. Chim. [3] 1, 425—429.

WHEN starch is treated with diastase under the ordinary conditions the starch is first converted into maltose and dextrin and the diastase then, by some ulterior action, changes the dextrin into maltose. This secondary reaction ceases, however, when the wort contains a certain percentage of maltose, so that a considerable quantity of dextrin always remains unchanged. Payen showed that the accumulation of maltose in the wort is the cause of the cessation of saccharification, and that if the maltose is fermented by the addition of yeast the action of the diastase recommences.

O'Sullivan attributed this subsequent saccharification to the joint action of the yeast and diastase on the dextrin, whilst Kjeldahl assumed that it was due, not to the removal of the maltose, but simply to a prolongation of the time during which the diastase is allowed to act, so that if a wort were kept long enough saccharification would be as complete as is the case after it has been fermented.

A wort that had been treated with excess of diastase and contained in consequence the maximum quantity of maltose was kept at 62° for several days in contact with diastase and a mixture of phenylhydrazine hydrochloride and sodium acetate, sufficient to combine not only with the maltose (2.73 per cent.) present in solution, but also with that which would be formed by the subsequent saccharification of the dextrin (1.163 per cent.) added to the mixture. 3.236 grms. of maltose were precipitated in the form of the phenylhydrazine derivative, proving that about 50 per cent. of the dextrin which remained unchanged in presence of maltose was converted into sugar as soon as the maltose was precipitated from the solution.

A wort, previously treated with excess of diastase, was divided into two equal parts (A. and B.) and unequal quantities of the maltose precipitated by means of phenylhydrazine. The wort (A.) then contained 2.66 per cent. of maltose and 5.12 per cent. of dextrin; the other (B.) 6.34 per cent. of maltose and 4.112 per cent. of dextrin. Diastase was then added to both (A. and B.), and the solutions kept at 25°; after 48 hours A. contained 2.431 per cent. of dextrin, showing that 46.7 per cent. of the quantity present had been converted into maltose, whilst B. contained 0.545 per cent., 13 per cent. of the dextrin present having been saccharified. The ratio of maltose to dextrose in the two worts had thus become almost identical.

A wort, previously treated with excess of diastase, was divided into two equal portions (A. and B.) of 100 cc. each, from one of which the whole of the maltose was precipitated with phenylhydrazine; their composition was then—

	Per Cent.
A. { Maltose	Traces.
{ Dextrin	5.06
B. { Maltose	2.44
{ Dextrin	4.52

The same quantity of diastase was added to each, and the solutions kept at 25°. After 24 hours 1.998 grms., and after 72 hours 3.187 grms. of dextrin had been saccharified in A., whilst in B. 2.125 grms. of dextrin were converted into maltose in 24 hours, and no subsequent saccharification occurred. The composition of the solutions was then—

	Per Cent.
A. { Maltose	3.363
{ Dextrin	1.873
B. { Maltose	4.603
{ Dextrin	2.396

These results show that Payen's view is correct, and that, as soon as the sugar is removed with yeast or phenylhydrazine the diastase commences to act on the dextrin again.—F. S. K.

Mucic Fermentation. E. Kramer. Monatsh. Chem. 10, 467—505.

BY mucic fermentation the author understands the process which causes solutions containing sugar (saccharose, glucose, lactose, &c.), or other carbohydrates (mannite, starch, &c.), to become viscid in presence of the necessary quantities of albuminoids and mineral substances (sodium and potassium phosphate being essential). Besides this mucous matter, which must be regarded as a hydrocarbon of the formula $C_6H_{10}O_5$, mannite and carbon dioxide are nearly always produced. The occasional appearance of lactic and butyric acids, or of free hydrogen, in mucous liquids has no connexion with mucic fermentation. The latter is induced by certain bacteria, which differ according to the nature of the sugar contained in the fluid. *Micrococcus viscosus*, as described by Pasteur, is not one of these bacteria.

Liquids containing hydrocarbons may be divided into three groups as regards their becoming viscid. (1.) Liquids containing saccharoses, so long as they show a neutral or

slightly alkaline reaction, *e.g.*, solutions containing saccharose along with albuminoids and mineral substances; decoctions of barley, rice, wheat, &c. in presence of saccharose; the juice of carrots, sugar-beet, onions, &c. The fermentation is induced by Kramer's *Bacillus viscosus sacchari*. (2.) Acid glucose solutions containing the required albuminoids and mineral substances. Wine is the chief representative of this group. The viscosity in this case is brought about by Kramer's *Bacillus viscosus vini*. (3.) Neutral or nearly neutral solutions containing milk sugar besides albumen and mineral substances. Milk belongs to this category. The micro-organisms inducing this fermentation differs from those which cause that process in the (1.) and (2.) group. The characteristics of the two above-mentioned bacteria are described. The mucous product of this fermentation is a result of the assimilation of the ferment, and probably consists essentially of external layers of the membrane which have swelled or been converted into mucous matter. The mannite formed in mucic fermentation must be regarded as a secondary product of an inner respiration of the above bacteria. The primary products are carbon dioxide and hydrogen, which latter converts the glucose into mannite. The mucous substance is not a gum, but a carbohydrate of the formula $C_6H_{10}O_5$, possibly a metamorphosis of cellulose. Alcohol precipitates it from the viscid fluid as a white, amorphous substance, which swells but does not dissolve in water. It is not coloured by iodine. Caustic alkalis dissolve it, giving yellow solutions, from which alcohol precipitates white scales. The specific rotatory power for $\alpha_D = +195^\circ$.—A. R.

PATENTS.

Improvements in the Treatment of Spirits, Wines, and Beer for the Purpose of Ageing or Maturing them. Brin's Oxygen Co., Limited, London. Eng. Pat. September 22, 1888. 4d.

THIS invention has for its object the maturing or ageing of spirits, wine, and beer by treating them with oxygen under pressure. Any convenient apparatus may be used.

—A. L. S.

Improvements relating to the Production of Pure Ethylic Alcohol from Crude Spirits. H. H. Lake, London. From C. E. T. Müller, Berlin, Germany. Eng. Pat. 13,892, September 26, 1888. 8d.

THE invention is based on the fact that aldehyde, amyl alcohol, and the like impurities of crude spirit are less soluble than ethyl alcohol in a solution of certain alkaline salts of a certain concentration and temperature.

Among the salts which may be practically used are carbonates and hydrates of potassium and sodium, phosphate of sodium, sulphates of sodium, ammonium, magnesium, and zinc, and potash or ammonia-alum.

The apparatus consists of a series of settling vessels, three being a convenient number, and the process is conducted as follows:—

The first vessel is partly filled with crude spirit, when a solution of one of the above-mentioned salts of a specific gravity 1.19—1.24 is run on to a screen or grating placed at the top of this so that the solution falls through the crude spirit in a finely divided state. The solution settles to the bottom and then contains about 15 per cent. ethyl alcohol with some aldehyde, amyl alcohol, &c.; but the proportion of these latter to the ethyl alcohol is much less than in the crude spirit. This solution is then led through a pipe to the top of a second settling vessel similar to the first, but filled with refined spirit; the solution which settles to the bottom contains ethyl alcohol, aldehyde, &c., but in diminished proportion.

The same operation may be repeated in a third settling vessel if necessary.

The solution finally obtained is then distilled in any of the usual type of column stills, and the alkaline solution remaining in the still may be used in succeeding operations. The settling vessels are provided with suitable pipes, taps, &c., so that the operation may go on continuously; thus when the settlings are withdrawn from the first vessel further

quantities of crude spirit and alkaline solution are allowed to flow in at the top. When the crude spirit in the upper portion of the first vessel has become very rich in aldehyde, amyl alcohol, &c., the vessel is emptied, and being filled with refined spirit it becomes the third of the series, and so on.—A. L. S.

An Improved Apparatus for Acetifying Alcoholic Wash and Liquor in the Manufacture of Vinegar. J. C. Shears and A. Manbré, London. Eng. Pat. 14,328, October 5, 1888. 6d.

THE invention relates to a modification of "The Quick Process," by which it is claimed that the loss arising from the evaporation of aldehyde, &c., is diminished from 20—25 per cent. to 4—6 per cent. The acetifying chambers are arranged in columns. Each chamber is two-thirds filled with beech-wood shavings; a series of holes is bored in the upper third of each chamber for the free admission of atmospheric air, and the bottoms of the chambers are finely perforated. On the top of the column is placed a delivery box with a finely perforated bottom, and at the bottom of the column is placed a tub to receive the vinegar.

The process is conducted as follows:—The alcoholic liquid is heated to a temperature of 85° — 100° F. in a tub half-full of beech shavings until acetification commences; the liquor is then run into the delivery box and allowed to run down the column. If the alcoholic liquid be not of greater strength than 5 per cent. absolute alcohol, it will be completely converted into vinegar by running through a column of four chambers; but if the strength be greater than this it must be run through once or twice more until the acetification is completed.—A. L. S.

Improvements in the Preparation of Fermentable, especially Brewers', Worts. C. R. Bonne, London. Eng. Pat. 1,582, January 29, 1889. 6d.

THIS is an invention for producing from brewers' grains and other similar products a solution of albuminoids which may be added to wort in cases where this latter does not contain sufficient nitrogenous material for the healthy growth of the yeast. The refuse (spent cereals from breweries, distilleries, vinegar breweries, starch manufactories, and such like) is washed with water to remove all traces of saccharine matter which it may contain, and which if allowed to remain would tend to discolour the product; it is then mixed with water to the consistency of a gruel (*i.e.*, 6—7 parts water to 1 part of dry matter), and introduced into a closed vessel capable of withstanding a pressure of four atmospheres and heated to 300° F., the heat being maintained 3—5 hours. The undissolved matter is then filtered off and the solution containing peptonised albuminoids added to the wort in the quantity required. The addition may be made at any stage between the mashing and fermenting, but the inventor recommends it at the mash tun. The beer brewer will find it sufficient to treat 3—10 per cent. of the grain in this way. In the case of distillers' wash, instead of washing the refuse to remove sugar, it is more convenient to add .05—.01 per cent. of tartaric acid or its equivalent of hydrochloric acid, this obviously could not be done by the beer brewer.—A. L. S.

Improvements in the Distillation of Alcoholic Liquids. J. Leslie, Belfast. Eng. Pat. 8277, May 18, 1889. 4d.

THE inventor claims that by the introduction of free or nascent oxygen or ozonised air into the liquid during distillation or into the alcoholic vapour during rectification, a spirit is obtained which is at once mellowed, and rapidly matures, as the fusel oil and other high alcohols are thus converted into aromatic ethers.

The following process is recommended:—

Barium dioxide is introduced into the pot together with the charge, and when the distillation is about to commence, a continuous flow of dilute hydrochloric acid is admitted by a pipe reaching nearly to the bottom of the still.

A similar result may be obtained in the "patent still" by continuously admitting into the rectifying column an acidified solution of barium dioxide or a solution of hydrogen dioxide previously prepared by dissolving barium dioxide in hydrochloric acid under pressure.

The quantity of barium dioxide to be used varies with the nature and requirements of the spirit operated upon; for every 100 gallons of "pot still spirit" to be drawn, from 50—100 oz. of barium dioxide treated with its equivalent of dilute hydrochloric acid may be taken as a basis.

—A. L. S.

Improvements in Treating and Utilising Spent Hops.
W. F. Snee, Weston-super-Mare. Eng. Pat. 10,656,
July 2, 1889. 6d.

A HORIZONTAL steam boiler (Cornish pattern) is erected, having a cylinder through it sloping from front to back at an angle of about 10°. Within this, and forming its inner lining, is a revolving wire drum ($\frac{1}{8}$ -inch mesh), and through the centre of this a fixed Archimedian screw.

The cylinder is heated to about 200° F., either by steam injected into the boiler, or by means of steam generated in the boiler by a furnace beneath it. The spent hops are introduced into the upper end of the cylinder by a hopper, and the wire drum being made to rotate, they pass continuously along the cylinder to its lower end, where they are ejected dry, and may be used as a litter for horses and cattle, for packing, and other purposes.—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

Decomposition Products of Casein. E. Drechsel. Jour. prakt. Chem. 39, 425—429.

THE author has previously drawn attention to the fact that strong acids and bases have not, as is generally supposed, an identical action on albumen, but that, although ammonia and amido-acids are always formed, carbonic anhydride, acetic acid and oxalic acid are only produced when baryta is employed. Hlasiwetz and Habermann found that when casein is heated with concentrated hydrochloric acid, in presence of stannous chloride, ammonia and several crystalline products, namely, leucine, tyrosine, glutamic acid and asparaginic acid are obtained, but no other crystalline compounds can be isolated. Horbaezewski showed later that other albuminoids give, under the same conditions, identical decomposition products, and sometimes sulphuretted hydrogen as well; Schützenberger, by treating various albuminoids with baryta at a high temperature, obtained the same products and, in addition, amido-acids, carbonic anhydride, oxalic acid, and acetic acid.

The author repeated the experiments of Hlasiwetz and Habermann; after boiling for three days the amido-acids were separated, and on treating the filtrate with phosphomolybdic acid, a dense precipitate was obtained. The precipitate was washed with 5 per cent. sulphuric acid, decomposed with baryta, the filtrate freed from baryta with sulphuric acid, and the solution evaporated with excess of hydrochloric acid. The residue was treated with a little water, dissolved in absolute alcohol, and the solution mixed with ether, whereon a large quantity of an oily substance was precipitated, and after a time partially crystallised. The crystals were separated, washed with absolute alcohol, in which they are only sparingly soluble, and dried over sulphuric acid. This compound is the hydrochloride of a strong base, and when treated with silver carbonate in aqueous solution it yields an alkaline liquid which, on evaporation, gives a crystalline residue. The *platinochloride* of the base crystallises in reddish-yellow prisms and has the composition $C_7H_{12}N_2O_2$, $H_2PtCl_6 + 4H_2O$. On adding alcoholic platinum chloride to the mother-liquors from the

crystalline hydrochloride a lighter coloured, hygroscopic *platinochloride*, $C_8H_{14}N_2O_2$, $H_2PtCl_6 + H_2O$, of another base is precipitated.

The crude mixture of chlorides is not decomposed by concentrated hydrochloric acid at 150°, but at 120°—130° it is decomposed by baryta with liberation of carbonic anhydride.—F. S. K.

Influence of Saccharine on the Digestion. A. Stift. Bied. Centr. 18, 458—460.

CONTRARY to the experience of Bruylants, the author finds that saccharine is not absorbed by the blood, but that it is wholly expelled from the system unchanged.

In one experiment, the author took saccharine daily for eight days in doses of 3 grms. per diem, when he found that it acted as a slight purgative, without however affecting the general health in any other way.

Other experiments conducted by the author were made with a view of ascertaining the effect of saccharine on the artificial digestion of albuminous and pepsin substances. These experiments point to the conclusion that a retardation of the digestion of such substances as meat-fibrin and egg-albumen is experienced in the presence of saccharine, the extent of such retardation depending on the time and quantity of saccharine present. Similar effects were noticeable in the case of starch and diastase, the fermentation being retarded.—J. W. L.

PATENT.

Improvements relating to Thermometers. A. Keddle, Belfast.
Eng. Pat. 9200, June 3, 1889. 6d.

THE invention consists in the adaptation of thermometers to testing the temperature of mixtures, either dry or liquid, such as bread-stuffs, in the state of "sponge." The thermometer is fixed at the lower end of a pointed holder, and is protected by a zinc shield which gives ready access to, and allows free contact with the "sponge" or mixture the temperature of which is desired. The thermometer may be further protected by a glass over the scale.—E. S.

XIX.—PAPER, PASTEBOARD, Etc.

Esparto. Chem. Trade J. 1889, 97—98, 115—116 and 130—131.

THE use of this raw material in paper manufacture continues to be confined, for the most part, to the United Kingdom. The annual import exceeds a quarter of a million tons.

In the first operation of dusting and picking, the raw material sustains a loss of about 6 per cent. in weight. The fine dust from an *esparto* "willow" was found to have the following composition:—

Water	6.2
Organic matter	64.6
Mineral matter	29.2

The organic matter consisted chiefly (90 per cent.) of the cuticular waxes and resins; the mineral matter left after ignition was analysed with subjoined results:—

Silica	56.42
Calcium carbonate	19.17
Magnesium carbonate	3.76
Alumina	20.57
Total	99.92

The silica in this dust is chiefly adventitious, *i.e.*, due to adherent sand. The silica of the grass itself preponderates in the ash, the proportion of which is about 3.5 per cent. of the weight of the *esparto*, after cleaning by dusting.

The percentage of cellulose isolated by the laboratory process varies from 45, in the African sorts, to 48 in the Spanish. The yield of pulp to the paper maker is consider-

ably lower than their "theoretical" numbers, viz., about 40 per cent. in the case of the Spanish varieties, and less for Arzew, Oran, and Tripoli, in the order named. The higher proportion of caustic soda required for boiling the

coarser varieties, prejudicially affects the yield of cellulose in correspondence.

The subjoined table sets forth the chief laboratory and working data of treatment of the various kinds of esparto:—

Variety.	Composition of Esparto.			Per Cwt. of Grass.		Lb. of 60 per Cent. Caustic Soda on 100 lb. of Extractable Organic Matter.
	Fibre or Cellulose.	Water and Ash.	Extractable Organic Matter.	Extractable Organic Matter.	Caustic Soda, 60 per Cent. used in Digesting.	
Spanish.....	Per Cent. 48·6	Per Cent. 12·6	Per Cent. 38·8	43·45	13·5	31·07
Oran.....	44·1	14·6	41·3	46·30	16·5	35·67
Tripoli.....	40·3	16·1	43·6	48·83	20·0	40·55

To remove a given quantity of the extractable organic matter, 15 per cent. more soda is required for Oran, and 32 per cent. more for Tripoli, than for the Spanish varieties. The increased quantity is partly accounted for by the increased volume of lye necessary to cover the coarser kinds; this again will depend upon the construction of the boilers. The points requiring special study with the view to the most economical adjustment of the conditions of the digestion are: (1) concentration of lye; (2) quantity of lye, *i.e.*, proportion to grass; (3) steam pressure, *i.e.*, temperature of digestion; (4) duration. From the general discussion of these contained in the paper, valuable information should be obtained in regard to the solution of the problem in particular cases.—C. F. C.

The Utilisation of Fibrous Peat for the Manufacture of Brown Paper, Wrappers, and Millboards. J. A. London. (Paper read before the Mechanical Science Section, Brit. Assoc., Newcastle Meeting, 1889.)

THE author stated that there were 3,000,000 acres of bog land in Ireland, in a great part of which the necessary fibrous variety of peat could be found, and pointed out the benefits which would accrue from its utilisation. The machine used for treating the material was a "Willow," or "Devil," having a drum 3 ft. in diameter and 12 in. on the face. The drum was covered with a cone-shaped casing. Both drum and casing had cone-shaped teeth, this shape preventing the fibre from adhering to the teeth, but the latter could be adjusted to produce fibre of any degree of fineness. The fibre could be treated in either a wet or dry state. The author further stated that paper made from peat fibre was stronger than that in which wood-pulp was used. White papers on the other hand could not be prepared from peat fibre. So far five mills were working on peat fibre.

PATENTS.

A New and Improved Blowing-out and Washing Process in Making Paper Pulp from Esparto, Straw, and other similar Vegetable Substances. C. F. Dahl, London. Eng. Pat. 11,150, August 1, 1888. 6d.

ACCORDING to this invention esparto, straw or other fibrous materials is boiled under a pressure of 45 lb. per square inch. When the boiling is completed the contents of the boiler is forced under pressure into a cylindrical vessel furnished with safety-valves loaded to 8 lb. This causes the material to be broken up into the state of pulp. Water is forced into this second vessel for the purpose of washing the pulp.—E. J. B.

An Improved Method of Producing Pure Cellulose. H. and C. Bache-Wug and V. B. Drewsen, Böhm, Norway. Eng. Pat. 11,458, August 8, 1888. 4d.

THE inventors treat crude cellulose from wood, straw, esparto, &c. with a solution of a permanganate acidified with sulphuric acid. The precipitated manganese dioxide is removed with sulphurous acid, sodium thio-sulphate or oxalic acid. The process may in certain cases be preceded by a treatment with bleaching powder solution.—E. J. B.

Improved Method of Destroying the Noxious Fumes or Gases arising from Chemical Manufactures or Processes. A. N. Bertram, Milngavie. Eng. Pat. 11,841, August 16, 1888. 6d.

THE gases (especially those arising from the recovery of soda from paper-mill lyes) are drawn into an air-tight brick chamber by a rotary fan, upon the blades and boss of which impinge jets of water. They next pass over one baffle wall and under another, encountering at each wall further jets of water. Water is also allowed to stand upon the floor to a depth of say 12 in.—A. R. D.

Improvements in Apparatus for Straining Paper Pulp and the like. W. Hall, Darwen. Eng. Pat. 12,502, August 30, 1888. 6d.

THE patent strainer consists of two boxes, one of which works inside the other. The moveable box is furnished with strainer plates, and is raised and lowered by a cam placed on a revolving shaft underneath.—E. J. B.

An Improved Method of and Means for Protecting Apparatus used in the Manufacture of Sulphite Cellulose. F. Salomon, Berlin, and H. Brünger, Cunnorsdorf, Germany. Eng. Pat. 13,396, September 17, 1888.

THE improved method consists in exposing the iron boiler plates while heated to the action of a solution of calcium bisulphite.

The latter "boils where it is in contact with the hot walls, and is thereby partly decomposed, the result being the deposition of a firm, dense, permanent crust of about $\frac{1}{2}$ to 2 mm. in thickness. This crust is composed mainly of gypsum (formed by the oxidation of calcium sulphite) and calcium monosulphite, and is so dense that it protects the underlying surface from the destructive action of the lye."—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Mandragora Alkaloids. F. B. Ahrens, Annalen, 251, 312—316.

THIS paper describes two alkaloids which have been obtained from the mandragora root possessing physiological properties very similar to those of atropin, and presumably closely related to it in their chemical constitution. The roots were powdered, macerated eight days with alcohol, and pressed. The alcohol was distilled off from the filtrate, the residue extracted with very dilute acid, and this solution, after neutralisation with potassium carbonate, extracted with ether. On distilling off the ether, the alkaloid remained as a slightly coloured brittle gum, after standing over sulphuric acid. It melts at 77°—79°, becomes moist on exposure to air, and its ethereal solution reacts alkaline. The sulphate

crystallises in small white deliquescent plates, and a solution introduced into the eye caused an enlargement of the pupil. The name *Mandragorin* is proposed for this alkaloid, which was further characterised by the following salts:—The gold chloride double salt, $C_{17}H_{23}NO_3 \cdot HClAuCl_2$ melts at 153° — 155° , and crystallises in shining plates from water, in which it is sparingly soluble in the cold. The chloro-platinate crystallises in small nodules, and melts at 194° — 196° . The mercuric chloride double salt melts at 160 — 161° , and crystallises from water in white needles. Mandragorin is not converted into atropin by the action of alkalis. A second alkaloid was obtained from the mandragora root after extraction with alcohol, as described above, by extracting the residue with water containing hydrochloric acid. This solution was evaporated, supersaturated with potassium carbonate, and extracted with ether, which when distilled off left an oily residue. The sulphate was not obtained in a crystalline form, but its solution caused an enlargement of the pupil. The platinum chloride double salt is a yellow crystalline precipitate melting at 179° — 181° . The gold salt melts at 147° — 153° , and crystallises in yellow plates or needles, and the mercuric chloride double salt crystallises in transparent feather-like needles, which become white and opaque when dried on the water-bath. The quantity obtained of this alkaloid was too small to allow of its composition being determined, but it is assumed to be isomeric with the atropa alkaloids. The following table gives the properties of the double salts of the isomeric alkaloids $C_{17}H_{23}NO_3$.

—	Gold Chloride Double Salt.	Platinum Chloride Double Salt.	Mercuric Chloride Double Salt.
Atropin.....	Oil gradually crystallising. Melting point 135° — 137° .	Yellow gummy precipitate. Monoclinic crystals by evaporating the solution.	Gummy precipitate.
Hyoseyamin....	Shining irregular plates. Melting point 160° (162°).	Triclinic crystals by evaporating the solution. Melting point 207° — 210° .	Oil solidifying to plates.
Hyosein.....	Flat yellow shining prisms. Melting point 198° .	Small octahedra soluble in ether alcohol.	Amorphous or oily.
Mandragorin....	Shining yellow plates. Melting point 153° — 155° .	Slightly soluble nodules. Melting point 194° — 196° .	Slightly soluble needles. Melting point 160° — 161° .
(?)	Plates or needles. Melting point 147° — 153° .	Bright yellow crystalline powder. Melting point 197° — 181° .	Transparent, flat feather-like needles.

—T. A. L.

On the Constituents of Herniaria. L. Barth and G. Herzig. Monatsh. Chem. **10**, 161—173.

Herniaria glabra and *Herniaria hirsuta* are herbaceous plants belonging to the family of the *Caryophyllaceae*, which have long been used as a popular remedy for ruptures, and have been included in the last edition of the Austrian pharmacopœia. The authors have experimented with a carefully selected quantity of *Herniaria hirsuta* with the result that the alcoholic extract contained various extractive matters and herniarin, which is the methylic ether of umbelliferone, and a glucoside which in character and toxic action resembles saponin, but with the difference that a splitting up by means of hydrochloric acid separates sugar and a substance containing one atom more of oxygen than saponin and hence named oxy-sapogenin, $C_{15}H_{25}O_3$. Herniarin forms a white crystalline powder easily soluble in alcohol and ether. It has the formula $C_{16}H_{15}O_3$, and melts at 117 — 118° C. When shaken with water or heated to 100° C. it

gives off an odour like that of coumarin. Its solubility in water is so small that one litre dissolved only 0.133 grm. herniarin, whence the authors observe that the active properties of the aqueous infusion of the plant cannot be due to this substance, but more probably to the glucoside which is present in the aqueous extract. Herniarin dissolves in concentrated sulphuric acid with a bluish-violet fluorescence and in caustic potash solution without fluorescence from which it is precipitated unchanged on acidifying. One kilo. of the plant yielded about 2 grms. of pure herniarin.—G. H. B.

On Caffeine. R. Leipen. Monatsh. Chem. **10**, 184—189.

This paper treats chiefly of the nature of the action of ozone on caffeine. The products of the reaction were ammonia, methylamine, carbonic acid, and dimethylparabanic acid, the decomposition being in all respects similar to that effected by potassium chromate and sulphuric acid. Theobromine treated in a similar manner remained for the most part unchanged by the ozone. In the course of this research the author had occasion to notice the exceptional stability of the oxalate of caffeine, which underwent repeated crystallisation from aqueous solution without decomposition, differing essentially in this respect from other salts of caffeine with inorganic and fatty acids.—G. H. B.

On the Constitution of the Cinchona Alkaloids. Z. H. Skraup and J. Würstl. Monatsh. Chem. **10**, 220—230.

A COMPARISON of the oxidation products of cinchonine, quinine, cinchonidine, and quinidine shows that in the first stage two different quinoline derivatives, cinchonic acid and quinic acid, are produced, but a further stage of oxidation yields the same two products from all four, namely, cincholoipon, $C_9H_{17}NO_2$, and cincholoiponic acid, $C_9H_{13}NO_4$. The authors now find that these products are yielded also by cinchonine and quinine. A part of the paper is devoted to a discussion of the relations between the cinchona alkaloids, but the matter is unsuitable for abstraction.

—G. H. B.

On Acid Salts of Mercury and the Halogens. G. Neumann. Monatsh. Chem. **10**, 236—241.

THE compounds here described are prepared by saturating the halogen acid with the mercury halogen salt at the ordinary temperature, and exposing the solution to a temperature of 0° C., or below, in an exsiccator over sulphuric acid and quicklime. The crystals thus obtained will decompose at a slight elevation of temperature or in presence of moisture. Compounds of the following formulae were obtained in crystals:— $HgCl_2$, HCl ; $HgBr_2$, HBr ; HgI_2 , HI . At a temperature of -12° C. the crystals contained a further molecule of acid, for example, $HgCl_2 \cdot 2HCl$.—G. H. B.

Camphonitrophenol. P. Cazeneuve. Bull. Soc. Chim. [3] **1**, 417—425.

Camphonitrophenol—

isomeric with nitrocamphor—

is obtained when α -nitrocamphor is boiled for half an hour with 10 times its weight of pure concentrated hydrochloric acid, but about 10 per cent. of the camphor is converted into an insoluble compound. The solution is diluted with three times its volume of water, agitated with animal charcoal, filtered, evaporated to dryness, and the residue recrystallised from boiling water. It loses its water at 30° , volatilises slowly at 100° , is soluble in water, alcohol, ether, chloroform, and benzene, and dissolves in boiling water in all proportions; it softens at 60° and melts at 70° , but the

anhydrous crystals melt at 220° with partial decomposition. Its specific rotatory power in 1.8 per cent. absolute alcoholic or benzene solution is $\alpha_D = +10^{\circ}$. It reddens litmus, gives a reddish colouration with ferric chloride solution, decomposes carbonates, and yields an acetyl derivative—

and an ethyl ether. When boiled with concentrated potash or when treated with sodium amalgam in the cold it takes up one molecule of water, and is converted into the compound—

Camphonitrophenol as an Antiseptic.—The author studied the antiseptic action of camphonitrophenol on *bacillus anthracis* and *staphylococcus pyrogenes aureus*, and found that 20 centigrammes are required to sterilise 15 cc. of aqueous salt-beef extract; it is only poisonous to higher animals when administered in large doses.

The camphonitrophenates are isomeric with the nitro-camphrates, but, unlike the latter, they are dextro-rotatory. The potassium, sodium, ammonium, copper, lead, zinc, iron, and barium salts are soluble in water, but the silver and mercury salts are only sparingly soluble, and the calcium salt is insoluble; the salts of quinine and cinchonine are also insoluble in water, but many alkaloids, morphine, for example, give soluble salts. The sodium salt—

prepared by boiling camphonitrophenol with excess of sodium carbonate, crystallises in needles, loses its water at 100° , and is readily soluble in alcohol. The calcium salt, $(\text{C}_{10}\text{H}_{14}\text{O.NO}_2)_2\text{Ca}$, can be prepared by precipitating aqueous solutions with lime water. The ammonium salt crystallises in colourless needles and sublimes at about 150° with slight decomposition.—F. S. K.

On some Bases found in the Shoots of *Solanum Tuberosum*. R. Fribas. Monatsh. Chem. 10, 541—560.

FRESH potato shoots were macerated and extracted with water containing 2 per cent. of acetic acid; the filtrate was rendered alkaline with ammonia, and the precipitate which collected dried, extracted with 85 per cent. alcohol, and filtered hot. A small quantity of ammonia being now added until just turbid, the solution on cooling deposited crystals and an amorphous body, the former solanine, the latter called by the author solanaine. These were further purified by frequent recrystallisation from alcohol. Both bodies are glucosides. Solanine melts at 244° , dissolves readily in dilute hydrochloric acid and 85 per cent. alcohol. Its composition is represented by the formula $\text{C}_{55}\text{H}_{93}\text{NO}_{18} + 4\frac{1}{2} \text{aq}$. Solanaine melts at 208° , it is more soluble in alcohol than solanine. It was not obtained in the crystalline form. The formula deduced from various analyses is $\text{C}_{52}\text{H}_{83}\text{NO}_3 + 4 \text{H}_2\text{O}$.

Both solanine and solanaine are, however, split up into the same substances by heating with dilute hydrochloric acid, viz., a sugar and solanidine hydrochloride. The sugar differs from dextrose in its action on polarised light, but its percentage composition is the same. The glucosazone prepared from it also resembles the corresponding dextrose compound. Heated with nitric acid neither mucic nor saccharic acid could be detected. The other product of the decomposition of the two bases is a crystalline colourless powder. Its formula is $\text{C}_{10}\text{H}_{13}\text{NO}_2 + \text{HCl}$. On treating its dilute alcoholic solution with potash, crystals of the free base solanidine were obtained, melting at 191° . The sulphate crystallises in colourless leaflets. A diacetyl-derivative was also prepared, melting at 203° .—A. R.

Betel Oil. J. Bertram and E. Gildemeister. J. Prakt. Chem. 39, 349—355.

THE leaves of *Piper betle* (L) from Southern China and Malay Archipelago yield an ethereal oil, betel oil, from which, using fresh leaves, Eykman (Chem. Zeit. 1888, 81) obtained a liquid phenol, "chavicol"—

a parahydroxyallylbenzene.

The authors, working on the dried leaves, found an entirely different phenol. The oil (of which .5 per cent. was obtained from the leaves) had a specific gravity of 1.024 at 15°C ., and yielded 70—75 per cent. of a phenol extracted by agitation with alkali and subsequently set free with acid.

The phenol distilled in vacuum yielded *Betelphenol*, $\text{C}_{10}\text{H}_{12}\text{O}_2$, boiling point 254° — 255° , sp. gr. 1.067 at 15° . Pure *Betelphenol* is an oily, colourless, highly-refractive liquid, with strong and persistent odour, and differing entirely from eugenol. Both give a green colour in alcoholic solution with ferric chloride, *Betelphenol* giving the deeper tint. The percentage composition is the same, but eugenol has sp. gr. 1.072 at 15° , and boils at 250° — 251° .

The authors prepared the acetyl-derivative, boiling at 275° — 277° and setting at -20° , remelting at -5° , the corresponding eugenol derivative boils at 270° and melts at 30° — 31° .

The Benzoyl-derivative crystallises in thin plates melting at 49° — 50° , the eugenol benzoate when pure melts only at 69° — 70° .

Acetylisoranillic acid, $\text{C}_{20}\text{H}_{10}\text{O}_5$, crystallising in slender needles or scales, soluble in water, melting at 250° , obtained by oxidation of the acetyl derivative with potassium permanganate. It is isomeric with the analogous acetylvanillic acid prepared in same way from eugenol. Thus the formula for *Betelphenol* will be—

$\text{C}_3\text{H}_5.\text{C}_6\text{H}_3(\text{OCH}_3).\text{OH}$ [$\text{C}_3\text{H}_5:\text{OH}:\text{OCH}_3 = 1:3:4$]
eugenol being—

$\text{C}_3\text{H}_5.\text{C}_6\text{H}_3(\text{OCH}_3).\text{OH}$ [$\text{C}_3\text{H}_5:\text{OCH}_3:\text{OH} = 1:3:4$]

Methyl ether of betelphenol. This was prepared and found to be identical with the corresponding derivative of eugenol and boiling at 247° to 248° . This confirms the correctness of the above formula. The methyl ether was also oxidised, and a crystalline salt obtained corresponding with that from eugenol methyl ether.

The second portion of the betel oil unaffected by agitation with alkali was fractionated, distilling mostly between 250° — 270° . This fraction was clear yellow, with a very pleasant odour of tea; on being mixed with double its volume of ether, and treated with hydrochloric acid and cooled in a freezing mixture, needle-shaped crystals slowly separated, melting at 117° — 118° . A sesqui-terpene dihydrochloride, $\text{C}_{15}\text{H}_{24} + 2 \text{HCl}$, of the same melting point has been obtained from a similar fraction of the oils of cubeb, saffron, patchouli, and others.—D. A. S.

On Carvol and Carvacrol Sulphonic Acid. A. Claus and W. Fahrion. J. Prakt. Chem. 39, 256—266.

EQUAL parts carvol and strong sulphuric acid 1.84 are gently mixed, vigorous action takes place, the pungent odour of carvacrol being evolved. By subsequent treatment the authors prepare an acid which they find to be identical with that from carvacrol, viz., *Carvacrolpara-sulphonic acid*—

It crystallises readily in large tables or flattened monoclinic prisms, easily soluble in water and alcohol, and soluble also in ether, melting at 65° — 69° (uncorr.) By further heating it is decomposed, giving off the odour of carvacrol. The authors describe the potassium, sodium, calcium, barium, and lead salts. The chloride is a viscid reddish-brown oil entirely uncrystallisable. The amide is insoluble in ether and benzene. On oxidation thymoquinone is obtained, pointing to the para-position of the sulphonic group to the hydroxyl.

Acetylcareacrol is a thick pale-yellow oil of not unpleasant odour.

The remainder of the paper is devoted to consideration of the constitution of carvol which shows the properties of a ketone.—D. A. S.

PATENTS.

Improvements in the Manufacture of Iodine by Electrolysis. T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 11,479, August 9, 1888. 4d.

ELECTROLYSIS is carried on in a vessel divided into two by a porous partition. In one compartment is an iron or other suitable cathode, immersed in a solution of a (preferably) caustic alkali. In the other is a platinum or other inoxidisable anode immersed in an acid solution of an iodide, preferably that of sodium or potassium. The iodide solution may be acidified by hydrochloric or sulphuric acid; or a soluble sulphate, such as that of magnesium, sodium, or potassium may be used, such sulphate being decomposed simultaneously with the iodide, and liberating the necessary acid. The reactions, which also indicate the proportions to be used, are given as follows:—

The solutions should be moderately concentrated. The iodine which collects at the positive plate is removed, washed, and then dried in a current of warm air.—E. T.

Improvements in the Manufacture of Salols and Analogous Ethers. C. Kolbe, Radheul, Germany. Eng. Pat. 13,169, September 12, 1888.

THIS is an improvement on M. von Nencki, Eng. Pat. 8018 of 1886 (this Journal, 1886, 577, and 1887, 561), referring to the manufacture of salols, by treating phenols and salicylic acid with dehydrating agents. In the present invention salicylic acid is replaced by the homologues, cresotic acids, and the isomeric compounds of *p*-hydroxybenzoic acid, or *p*-methoxybenzoic acid, or *p*-ethoxybenzoic acid.

In place of phenol or naphthol, cresol, thiophenol, and resorcinol monomethyl ether, $\text{C}_6\text{H}_4(\text{OCH}_3)\text{OH}$, may be employed.

Twenty-four new compounds are thus obtained, as for instance *o*-cresol salicylate, $\text{C}_6\text{H}_3(\text{CO}_2\text{C}_6\text{H}_4\text{CH}_3)\text{OH}$.

The compounds produced according to this invention are intended for use as medicaments and for the production of colouring matters.—O. J. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Certain Organic Reducing Agents as Developers. J. H. Stebbings. Meeting Soc. of Amateur Phot. New York.

Resorcinol.—The author has experimented with this substance, using carbonate of soda and carbonate of potassium, without, however, obtaining any satisfactory results. H. Tóth and Eder (Phot. Corresp. 17, 191), however, state that in an ammoniacal or caustic soda solution it reduces gelatinobromide plates very well, although somewhat slower than pyrogallol.

Amido-β-Naphthol-α-Sulphonic Acid.—This compound is slightly soluble in boiling water, but a trifle more so in an aqueous solution of acetate of soda, from which, on cooling, it crystallises out again. Alkalis and alkaline earths dissolve it very readily, and the solutions thus obtained, when left exposed to the air, rapidly turn orange-

brown. Oxidation products colour either the neutral or alkaline solutions of this acid yellow to brown. The most peculiar feature of this salt, as well as of those that are yet to be described, is that of the reduction of silver salts either in acid or alkaline solutions to extremely finely-divided metallic silver. This peculiarity would, in the author's opinion, make the new compound an extremely valuable one for use in developers.

Amido-β-Naphthol-β-Sulphonic Acid.—This compound is isomeric with the foregoing one, and may be obtained by reducing the orange dye-stuff produced by combining diazobenzene chloride with Schäffer's β-naphthol-β-sulphonic acid. It is obtained in small white crystals. In small quantities it may be dissolved in boiling water, without decomposition; and if the solution thus obtained be rapidly cooled down with ice, the amido-acid crystallises out unaltered in little snow-white needles. By slow cooling of the aqueous solution it is decomposed, gradually turning brown. In alkaline solutions it behaves similarly to alkaline pyrogallol. It likewise reduces silver salts to metallic silver.

Pyrocatechin (catechol), the third isomer of hydroquinone (quinol), is said to work very well. This substance crystallises in rectangular prisms belonging to the orthorhombic system. Eder and H. Tóth, in their experiments, used a 5 per cent. catechol solution, to which they added two or three drops of ammonia for every 20 cc.

Phloroglucol, $\text{C}_6\text{H}_3(\text{OH})_3$, an isomeride of pyrogallol, has also been tried by Eder, who states that even in a strong ammoniacal solution it works very poorly, as the reducing action is very slight. Perhaps in a caustic soda solution it might work better. This substance is best prepared by fusing resorcinol with caustic soda. It crystallises in hard rhombic prisms, having a very sweet taste.

Some time ago the author made a few tests with phenylhydrazine hydrochloride, and found that this substance in a caustic soda solution reduces chloride of silver very easily. He did not extend these experiments to bromide of silver, but has no doubt that it will reduce this too.

This compound may be prepared by reducing diazobenzene chloride with tin and hydrochloric acid. It crystallises in little pearly plates, which are quite soluble in water, and altogether it is a very remarkable compound.

In Ber. 21, 3468, is an article by O. N. Witt, entitled, "*Reduction Products from the Azo-colouring Matters of the Naphthalene Series.*" This article describes a number of compounds, which it would appear are likely to prove useful in photography, though the author has not heard of their being used, or even experimented with, for this purpose. (This Journal, 1889, 276.)

No doubt good results might be obtained, moreover, from paraphenylenediamine, which may be obtained by reducing paraniacetanilide with tin and hydrochloric acid; and from dimethyl-para-phenylenediamine, which may be obtained by reducing nitroso-dimethyl aniline with zinc dust. Both compounds, especially the latter, absorb oxygen from the air, and for this reason they might make good reducing agents.

XXII.—EXPLOSIVES, MATCHES, Etc.

Novelties in the Explosives Industry. O. Guttman. Dingl. Polyt. J. 273, 62—69.

An improved pattern of *Lauer's* friction tube is shown in Fig. 1. Each tube is tested with a strain equal to 8—10 kilos. before leaving the works. They are now being largely and successfully employed in the place of electric detonators. Figs. 2—3 represent Roth's safety fuse igniter. The fuse is surrounded either by a metallic case or wire gauze. The igniting composition in the globular form is fired either by means of a needle or by a drop of sulphuric acid, or by means of a friction rod.

Bickford and Co.'s safety fuse igniter is similar to Roth's, the ignition of the fuse being brought about by the breaking of a glass ball containing sulphuric acid.

In Zschokke's pneumatic igniter the needle, which is kept in position by means of a spring, is driven into the friction composition by air pressure.

As regards Zschokke's chemical igniter, a drop of sulphuric acid contained in a U-tube is blown into the chamber containing the friction composition.

Two explosions of blasting gelatin occurred in the magazines at Aden within a few weeks of each other. It seems probable that these explosions were due to the decomposition of the gelatin. The temperature alone is not sufficient to explain this accident. It is evident, however, that the construction of the magazine was favourable to the concentration of the sun's rays and that it was badly ventilated.

The author states that if blasting gelatin be exposed to a temperature of 70° for a length of time, the gun-cotton contained in it suffers decomposition, which under favourable circumstances may result in ignition.—C. N. H.

PATENTS.

Improvements in the Manufacture of Explosives. J. H. Johnson, London. From F. Engel, Hamburg, Germany. Eng. Pat. 6022, April 25, 1887. 6d.

This invention has for its object the manufacture of explosives for use in small arms and ordnance. It consists in nitrating woody matter, vegetable fibre, or cellulose, and then completely dissolving them in acetic ether or like solvent until they assume a plastic consistency. By distilling off the solvent the mass is reduced to a powdered or granular form.—C. N. H.

Smokeless Gunpowder. C. F. Hengst, Plunstead. Eng. Pat. 16,783, December 6, 1887. (Second Edition.) 6d.

Compare this Journal, 1889, 478.

Improvements in Smokeless Explosives. J. A. Wanklyn, London. Eng. Pat. 9799, July 5, 1888. 4d.

This invention relates to improvements in smokeless powders and consists in the admixture of dynamite or gun-cotton with nitrate of urea.—C. N. H.

Improvements in the Manufacture of Explosives. I. M. T. Anderson, Combs, and A. Anderson, Woolwich. Eng. Pat. 13,308, September 14, 1888. 6d.

This invention relates to the treatment of nitro-cellulose by acetic ether or other suitable solvent, the object being to form the explosive material into threads, strips, cylinders, tubes, or other forms by forcing it through slits or holes in a plate, and then, if required, cutting the threads, &c. into grains or rings.—C. N. H.

An Improved Explosive Compound. P. M. Justice, London. Eng. Pat. 13,789, September 24, 1888. 4d.

This invention relates to an explosive composed of "a suitable nitrate" coated with a hydrocarbon, such as paraffin or naphthalene, and rendered sensitive to detonation at the desired time by admixture with potassium chlorate.—C. N. H.

Improvements in the Manufacture of Dynamite. C. O. Lundholm, Ardeer. Eng. Pat. 14,027, September 29, 1888. 4d.

The object of this invention is to render dynamite not liable to injury or deterioration by water or moisture, and even capable of acting effectively whilst immersed in water. The invention consists in employing as the absorbent of the nitroglycerin the substance obtained by carbonising without access of air, a siliceous earth naturally containing organic or carbonaceous matter.—C. N. H.

Improved Methods or Means of Treating High Explosives, such as Dynamite, and for the Utilisation, Protection, and Firing of such Explosives in Projectiles, Torpedoes, Cartridges, and the like. R. S. Lawrence, London. Eng. Pat. 236, January 5, 1889. 1s. 3d.

This invention has reference to the treatment of high explosives, with a view to their employment in the charging of projectiles, torpedoes, mines, &c. The patentee encloses the high explosive within an envelope or hollow rope of flexible or elastic material. When the high explosive is in the form of dynamite it may be applied to one or both surfaces of a "sheet material." When nitroglycerin is used the material may be saturated with it. The sheet thus prepared may be cut up into suitable forms, fully described and illustrated in the specification. The projectiles charged with high explosives treated according to this invention are fired by specially-constructed time fuses.

The specification contains 20 claims and five sheets of drawings.—C. N. H.

A New Explosive. W. H. A. Kitchen and J. G. A. Kitchen, St. Helens. Eng. Pat. 11,102, July 10, 1889. 4d.

This invention relates to a mixture of chlorate of potassium, coal dust, and resin or sulphur.—C. N. H.

An Improved Manufacture of Smokeless Powder. W. Schückher, Vienna, Austria. Eng. Pat. 11,665, July 22, 1889. 4d.

This invention relates to smokeless powder of the following composition:—

	Parts.
"Nitro-starch".....	50
Saltpetre.....	40
"Nitrobenzol".....	10

The nitro-starch is subjected to the action of a solvent during the process, with a view to harden the finished product.—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

Apparatus for Electrolytic Work. N. v. Klobulow. J. Prakt. Chem. 1889, 40, 121—127.

The author has previously drawn attention to the importance of agitating an electrolyte when a metal is being determined quantitatively by electrolysis. This may be done either by a mechanical agitator or by blowing in air (after the manner which has been suggested as a means of reducing polarisation in single fluid batteries). The latter method appears at first sight to be easy, but it has serious defects, arising partly from the small dimensions of the electrolytic cell (a platinum basin) and partly from the difficulty of distributing the air or other gases uniformly. When air is used care has to be taken to avoid oxidation of the metal or the electrolyte; CO₂ cannot be used with alkaline liquids, and when the electrolyte contains volatile matters such as ammonia, ammonium sulphide, or hydrocyanic acid, the method appears to be inapplicable. Levoir has described an apparatus in which the positive electrode is placed beneath the negative, and the agitation of the electrolyte is effected by the ascent of the oxygen evolved on the lower electrode. But in many cases this is insufficient, and except where the metallic deposit adheres firmly it is not advisable to make the negative electrode the upper one.

The author therefore recommends that the deposition should take place in a platinum basin (which at the same time forms the negative electrode), and describes an arrangement in which the positive electrode acts as a

mechanical agitator. Reference is made to an "universal holder" described in the *J. Prakt. Chem.* **33**, 473, and figures are given illustrating a system of imparting motion to a number of agitators.

In the figure the apparatus for a single one is shown, and the agitator can be easily set in motion by a clockwork arrangement or a small electromotor. For a series of apparatus a running cord bearing against the pulleys C, can be used. K M is a kind of self-centring chuck which is attached to the spindle by the screw N; the electrode is fixed in the chuck by tightening the nut M. L is a cup-shaped guard which prevents dirt, &c. from falling into the electrolyte. The electrode O is slightly tipped as shown by the line *x x'*; this ensures a thorough mixing of the contents without any turbulent motion. Electrical connexion with the positive pole of the battery is made through the arm P. The negative pole is connected with the platinum dish R, upon which the metal is deposited.

There are some instances in which the above arrangement is impossible, e.g., where the electrolysis takes place between two flat plates or two concentric cylinders, or where mercury is used as one electrode. In such cases the form and disposition of the agitator must be altered. Where it need not at the same time be used as an electrode it can be conveniently made of thin glass rod which is easily bent to the required shape.—D. E. J.

Detection of Phosphoric Acid of Mineral Origin. J. Stocklasa. *Bied. Centr.* **18**, 444–446.

LORENZ's method for the detection of phosphoric acid of mineral origin is based on the supposition that mineral phosphates contain a considerable quantity of fluoride, whilst those of animal origin contain not more than a trace; the author finds, however, that some of the phosphatic minerals, such as Norwegian apatite, also contain but a trace of this element, and hence concludes that Lorenz's method cannot be relied upon in all cases.—J. W. L.

Use of Nitroso-β-Naphthol in Quantitative Analysis. *Zeits. Anal. Chem.* **28**, 234–238.

Separation of Copper from Lead, Cadmium, Magnesium, Manganese, Mercury, Zinc, &c. (See this Journal, 1887, 384.)—The following additional notes may be useful. In igniting comparatively large quantities of the precipitated and dried copper nitroso-β-naphthol, it is advisable to add a little pure ammonium oxalate or oxalic acid. Silver, should it be present in the solution, is precipitated along with the copper.

Separation of Iron from Chromium, Manganese, Nickel, Zinc, &c. (See this Journal, 1886, 41.)—At least 1 gm. of nitroso-β-naphthol is required in the precipitation of 0.1 gm. of iron. Small quantities of ferrous iron do not interfere with the quantitative separation of the iron. Not

more than 0.3 gm. of iron should be contained in the volume employed for precipitation. The filtrate from the precipitated ferri-nitroso-β-naphthol is rinsed into a good-sized Erlenmeyer's flask, an excess of ammonium hydrate and chloride added, and the manganese precipitated as manganic hydrate by a stream of air containing vapours of bromine. When chromium is present, 5 cc. of strong hydrochloric acid must be added to each 100 cc. of the solution, to prevent this metal being precipitated as chromium nitroso-β-naphthol, $(C_{10}H_7O.NO)_3Cr$.

Meineke points out that in the precipitation of iron, copper and cobalt, as well as phosphoric acid, are liable to be contained in the precipitate. (See also this Journal, 1885, 370, and 1888, 525.)—E. B.

Use of Potassium Manganate in Analytical Chemistry. *Zeits. Anal. Chem.* **28**, 238–239.

Ad. Jolles recommends potassium manganate for use in analytical work. It is prepared in the pure state by heating equivalent quantities of pure potassium permanganate and hydrate in a crucible, the potassium hydrate being first added and dissolved in a little distilled water, and whilst the crucible is gently heated the powdered permanganate stirred in. The crucible is then heated at a dull red heat for about two hours, allowed to cool, and the potassium manganate formed put into a glass-stoppered bottle. In presence of alkalis, potassium manganate dissolves in water without decomposition. Its alkaline solution is characterised by the property of yielding insoluble compounds of regular composition with certain metallic oxides. On this property the author bases processes for the volumetric estimation of manganese and cobalt.

To estimate manganese, the manganous salt to be tested is added to a weak alkaline solution of potassium manganate, whilst constantly shaking, till the green colour has disappeared and the upper portion of the liquid is colourless. In this manner and without using a zinc salt, a precipitate of manganese dioxide, which settles quickly and renders the end reaction easily perceptible, is obtained free from manganous oxide.

The change is represented by the following equation:

Cobalt is determined in similar manner; a precipitate of cobaltous manganate, $CoMnO_3$, being obtained.—E. B.

On the Estimation of Sulphuric Acid in the Presence of Iron. P. Jannasch and Th. W. Richards. *J. Prakt. Chem.* **39**, 321–334.

THIS is the first of a series of researches undertaken at the request of Victor Meyer on some irregularities in quantitative analysis. On account of its great practical importance the estimation of sulphur in pyrites was first investigated.

Fresenius (*Zeits. Anal. Chem.* **16**, 339; *Chem. Soc. J.* 1878, 650) recommended determination of sulphur in pyrites by fusion with a mixture of sodium carbonate and potassium nitrate, solution, separation of insoluble peroxide and precipitation with barium chloride in usual way. Lunge (*Handb. der Soda Industrie*, **1**, 96) objects to foregoing as being too complicated, and prefers the wet way, i.e., solution in nitric acid and subsequent precipitation. Fresenius (*Zeits. Anal. Chem.* **19**, 53) in reply made a series of pyrites analyses by Lunge's method; he found an average result of 1 per cent. too low, and indicated two sources of error, viz., the invariable presence of iron in the precipitate and the solubility of barium sulphate in acid, especially in presence of ferric chloride. Lunge (*Zeits. Anal. Chem.* **19**, 419) explained that this solubility occurred only in hot solutions and that the barium sulphate separated on cooling. He ascribed the high result of Fresenius to the decomposition in fusing, and consequent estimation of the useless sulphur (Heavyspar and Galena).

The authors, as the result of a long and careful series of experiments (directed in the first place to prevent precipitation of iron), condemn Lange's process and insist on that of Fresenius being the only accurate and reliable method of estimating sulphur in pyrites.

Four experiments were made with absolutely pure prepared ammonium ferrous sulphate, in two of which the iron was oxidised; in each case the barium sulphate was more or less coloured, and in the ferrous solutions 0.8 per cent. too low of SO_3 was obtained, and 0.002 per cent. of peroxide present, while from the ferric solutions the SO_3 found was 1 to 2 per cent. below the theoretical amount, while an average of 0.0157 of Fe_2O_3 was present.

Three experiments with organic acids, citric, acetic, and formic acids being used, were made, but without effect in preventing precipitation of iron. Complete reduction with zinc was tried, but both zinc and iron oxides were found in the precipitate.

A second series of experiments was made. 10 cc. of normal sulphuric acid were diluted to same proportions as in previous series of experiments and the same amount of hydrochloric acid added. The result of four experiments showed an average of 0.3984, as against the theoretical 0.3995. 2.5 cc. of a standard Fe_2Cl_6 solution (made by dissolving 56.1 grms. piano wire in hydrochloric acid and oxidising with chlorine) were added to each 10 cc. of $\text{N.H}_4\text{SO}_4$ and the determination made. The average of five experiments showed 0.3833 only, as against the former series 0.3984; a loss of 0.051, while 0.0144 grm. of Fe_2O_3 was found in the precipitate.

Other experiments showed there was no barium sulphate in the filtrate, and since, though soluble in hot ferric chloride, it separates on cooling, the error must lie not in loss by solution, but in loss on ignition. Ferric oxide and barium sulphate were mixed and ignited, but no loss was sustained. A portion of iron-contaminated precipitate was ignited in a Gooch's crucible, and weighed successively after heating at 150° , 250° , 500° , 700° , and after ignition; the colour gradually darkened and from 250° the loss of weight was apparent.

Finally, another portion was ignited in a platinum boat in a current of air and the gas absorbed in water. The water was acid to litmus and gave a strong precipitate with barium chloride, showing the loss was due to escape of sulphuric anhydride.

The authors advance the theory that a double sulphate of iron and barium is precipitated, and that this decomposes at 250° , leaving ferric oxide. If the figures of the experiments with $\text{N.H}_4\text{SO}_4$ in absence and presence of iron be calculated out to Fe_2SO_4 and thence to BaO , a striking confirmation of this theory is obtained. Thus the authors support the process of Fresenius.—D. A. S.

Determination of Nitric Acid by means of Ferrous Sulphate. Bailhache. Bull. Soc. Chim. [3], 2, 9—13.

This is a modification of Pelouze's method in which ferrous sulphate is substituted for ferrous chloride. 50 cc. of a ferrous sulphate solution containing 100 grms. of the salt and 75 cc. of monohydrated sulphuric acid are placed in a 250 cc. flask, and 25 cc. more of the sulphuric acid added. The flask is provided with a rubber stopper fitted with a stop-cock funnel and an exit tube. It is placed in a hot sand-bath capable of heating five flasks at once. 25 cc. of a saturated solution of sodium bicarbonate are first added by means of the funnel to expel the air, and when this has been effected the solution of nitrate is run in. The nitric oxide comes off quietly, and when the evolution is ended another 25 cc. of the bicarbonate solution are added to drive out the last traces of the gas. The boiling is then continued for five minutes, the contents of the flask allowed to cool and made up with previously boiled water to the containing mark. The unoxidised ferrous sulphate is then titrated by potassium bichromate in an aliquot portion of the solution. Satisfactory analyses are given, the results obtained by this method compared with those got by the Schloesing-Grandean modification of Pelouze's method agreeing very well. The

ferrous sulphate solution keeps well when preserved in a flask attached to a CO_2 generator; its value must be fixed by the bichromate from time to time; five determinations can be effected within an hour if they are carried on simultaneously.—C. A. K.

On the Use of Standard Solutions of Ammonia. R. Rempel. Zeits. f. angew. Chem. 1889, 331—332.

If a normal or semi-normal solution of ammonia be titrated with standard acid the amount of ammonia found will be too low owing to its volatility, and the amount of loss is influenced by the time allowed to elapse before the titration is performed and also by the nature of the vessel in which the ammonia is titrated. Solutions were accurately standardised by adding the ammonia solution from a burette to the solution of acid. Titrations were then made by the reverse process, i.e., adding the standard acid to solution of ammonia, with the following results:—

Vessel in which the Ammonia Solution was Titrated.	Number of cc. of Normal Acid required to Neutralise 20 cc. Semi-Normal Ammonia.			
	Titration performed at once.	Titration performed after standing Five Minutes.		
	Litmus.	Methyl- Orange.	Litmus.	Methyl- Orange.
Erlenmeyer flask of 200 cc. capacity.....	10.00	10.00	10.00	9.97
Beaker of 200 cc. capacity.....	9.90	9.94	9.75	9.80
Deep porcelain basin...	9.70	9.75	8.90	8.80
Shallow porcelain basin	9.43	9.50	7.81	7.75

The author is of opinion that a semi-normal solution of ammonia is the strongest that should ever be used and prefers a weaker solution, and recommends that the standard ammonia be always added to the acid and the burette filled without allowing the ammonia solution to come in contact with the outside air.—E. E. B.

Examination of Sodium Carbonate. R. Kissling. Zeits. f. angew. Chem. 1889, 332—334.

Sodium carbonate is frequently used for standardising solutions of acid for volumetric analysis, although the author prefers potassium tetra-oxalate ($\text{KHC}_2\text{O}_4 \cdot \text{H}_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$), as its purity can be easily tested by igniting it and weighing the potassium carbonate. To render sodium carbonate quite anhydrous it is usual to heat it to redness before weighing out the quantity required for the standard solution, but the author has proved that sodium carbonate loses carbonic acid at as low a temperature as 500° , and that sodium carbonate which has been heated to that temperature invariably contains caustic soda. Anhydrous sodium carbonate can, however, be obtained by heating pure sodium bicarbonate in an air-bath at 150°C .

Dobbin's process for detecting sodium hydrate in the presence of sodium carbonate (this Journal, 1888, 829—830) is considered good, but it is pointed out that it cannot be used for determining sodium hydrate quantitatively in the presence of a large excess of carbonate. The addition of a trace of caustic ammonia to the double iodide solution is preferred to the trace of ammonium chloride recommended by Dobbin, and the solution should not contain an excess of potassium iodide. If a larger quantity of free ammonia be added ammonium carbonate and sodium hydrate would be formed.—E. E. B.

Determination of Lime in Presence of Phosphoric Acid, Iron, Aluminium, and Manganese. O. Reitmar. *Zeits. f. angew. Chem.* 1889, 357—362.

AFTER numerous experiments with Thomas slag as a convenient material, the author formulates the following process:—

The substance to be analysed is dissolved and the silica separated in the usual way, the solution containing all the bases being treated by Classen's process for the direct estimation of lime (Classen, *Quant. Analyse*, 2nd edit., p. 24, and *Zeits. Anal. Chem.* 1879, 391). The method described by Classen consists in treating the hydrochloric acid solution containing the substances enumerated in the heading with potassium oxalate in quantity sufficient to make oxalic acid the only free acid in solution; calcium oxalate separates, phosphoric acid being left in solution. The resulting calcium oxalate is free from phosphoric acid, but contains traces of the oxalates of the other bases present, especially that of manganese; after ignition and a repetition of Classen's process it is obtained pure, and can be weighed as oxide, or the oxalic acid titrated with permanganate solution. A shorter plan, but one somewhat less accurate, is to dissolve the first precipitate of calcium oxalate in hydrochloric acid, and to reprecipitate it in acetic acid solution. Using either method, filtration takes place readily.

The author recommends the use of the burette-tap shown in the figure, in place of the ordinary stop-cock for titrations

with permanganate. As will be seen, the upper and lower surfaces move over each other in a horizontal plane, being held in position by the central pivot and by the rubber bands at the side. These latter enhance, by their action under torsion, the ease with which the liquid may be allowed to fall in distinct single drops when nearing the end of a titration.—B. B.

Detection of Cochineal in Foodstuffs. *Jour. de Pharm. et de Chim.* 18, 489.

Lagorge makes an aqueous or dilute alcoholic solution of the foodstuff, acidifies with a few drops of acetic acid, and extracts with amyl alcohol. Water is added to the amyl alcohol solution and the mixture evaporated on the water-bath till the alcohol is expelled, and an aqueous solution remains. According to the amount of the colouring matter of cochineal present, a green-blue colouration or precipitate is produced on the addition of a 3 per cent. aqueous solution of uranium acetate. The colour changes to orange when acid is added. Ammoniacal carmine under the same conditions gives a red- or blue-violet, logwood a violet, peach-wood a brown-red, and elder berries a violet, precipitate or colouration.—E. B.

Colour-Reactions of Organic Compounds. *Zeits. Anal. Chem.* 28, 244—252.

E. NICKEL, in a recent publication, classifies in the order below the colour-tests commonly applied for the detection of organic bodies.

Colour-tests with Nitrous Acid, excluding the Formation of Azo-Compounds.—The reagents of Millon, Hoffmann, and Plügge, produce almost identical colourations with the mono-hydroxy- and methoxy-derivatives of aromatic hydrocarbons. The same reagents also give colourations with aromatic hydroxy-compounds, containing aldehyde- or carboxyl-groups, or side-chains in which hydroxyl- or amido-groups are present. One or two drops of the reagent are added to 1 cc. of the solution to be tested; usually the colouration is most intense when the mixture is heated to 60° or 70° or even 100°, but frequently, as with thymol, for example, heat destroys the colouration first produced. Only monophenols yield full colourations with Liebermann's reagent, the majority of polyphenols giving pale yellow tints, but, exceptionally, a full red colouration is obtained with orcinol. As the reaction proceeds in two stages, nitroso-phenols being formed in the first stage, which are then condensed with the unaltered phenols, the test can be so modified that phenols and sulphuric acid may be employed to detect nitrophenols. The author finds that, in some cases, a condensation in Liebermann's reaction may be effected with metallic salts. Thus vanillin gives a fine violet colouration on being heated with a solution of mercuric chloride containing potassium nitrite, and a solution of phlorizin becomes blue or violet when heated after the addition of zinc sulphate and a fairly large amount of potassium nitrite.

Colour-tests in which Azo-Compounds are produced.—

The sulphates of aniline and its homologues may be advantageously used along with potassium nitrite in Weselsky's reaction, instead of the nitrate of aniline and potassium nitrite recommended, or the diazo-salts may be directly used. Among substances of minor technical importance, red colourations are obtained with phloroglucinol, catechin, and maelurin. Phenols almost invariably yield yellow or brown colours, but resorcinol and phlorizin give red colours, as also do several aldehydes. To this group of reactions belongs also Ehrlich's test with para-diazobenzenesulphonic acid.

Colour-tests with Formation of Triphenylmethane- and similar Compounds.—

In the presence of acid such phenols as common phenol, catechol, resorcinol, quinol, pyrogallol, and phloroglucinol act as excellent colour reagents for aldehydes, and conversely aldehydes may be used to detect the phenols mentioned. As a reagent for detecting lignine, the author assigns the foremost place to phloroglucinol, which he considers better for the purpose than orcinol and resorcinol. Many aldehydes give colourations with the sulphates of aniline, toluidine, &c.; vanillin, for instance, as was shown by Singer, gives a yellow colour with aniline sulphate, as does also salicylaldehyde; on the other hand, no colouration is obtained with cinnamol. Of the glucosides coniferin alone gives a pale yellow colouration, when tested in solution with aniline hydrochloride, but a much deeper yellow when tested in the dry state, and especially after the addition of acid. The salts of aniline, &c. can also be used as reagents for lignine. Potassium hydrogen sulphite, it is stated, interferes with these tests. The reactions of Lustgarten and the furfural reaction of Stenhouse belong to this group.

Colour-tests with Salts of Iron and Chromic Acid.—

Ferric chloride gives colourations with a large number of organic bodies; it should be applied in the form of a dilute aqueous solution. Three classes of aromatic compounds yield colourations with ferric chloride, namely, compounds containing a hydroxyl- or an amido-group in the benzene nucleus and carboxylic acids. The influences of other additional hydrogen-replacing groups, both from the natures of the groups and their positions in the benzene nucleus, on the colourations obtained with the aromatic hydroxy-compounds, are fully considered in the original paper. In connexion with Sanio's proposal to employ potassium bichromate in the micro-chemical testing of astringent matters when dark red or brown precipitates are obtained, the author discusses the extent of reliance which may be placed on the indications of this reaction. Several phenols, namely, catechol, quinol, pyrogallol, and hot solution of α -naphthol, give brown colourations or precipitates; resorcinol does not give a colouration,

nor do guaiacol, oreinol, and phloroglucinol. Gallie acid gives a copious precipitate, but protoeatechnic acid gives only a colouration and no precipitate even in a concentrated solution. Certain amines, notably aniline and xyldine, also give brown colourations with bichromate solution. Lastly, attention is called to the colourations induced by the oxidising influence on the alkaloids of the chromic acid liberated by the use of an acid with bichromate solution.—E. B.

Test for Lanolin. Zeits. Anal. Chem. **28**, 256—257.

G. Vulpinus dispenses with the use of acetic anhydride in the detection of lanolin by the following test:—The solution of a few centigrammes of lanolin in 5 cc. of chloroform is carefully poured on to the surface of an equal volume of concentrated sulphuric acid, when a brown-red ring is produced, which increases in intensity for 24 hours, by which time small red-brown solid particles attach themselves to the sides of the test-tube immediately round the coloured ring, and the chloroform above the dark-coloured layer has a violet tint. On treating in the same way lard, wax, oil of almonds, olive oil, mineral grease, and tallow, only more or less yellow-coloured rings are produced; darker rings are produced with sperm oil and American vaselin, but the colouration obtained with vaselin is a pure brown, the chloroform being tinted similarly, whilst sperm oil alone gives a coloured ring resembling that obtained with lanolin when it is present in larger proportion than the latter.—E. B.

A New Reaction for Proteids. C. Reichl. Monatsh. Chem. **10**, 317—320.

THE proteids react with benzaldehyde in presence of sulphuric acid to form blue colouring matters. In testing a solution for the presence of proteids the aldehyde is added in small quantity; afterwards, sulphuric acid (50 per cent.) in large quantity; lastly, one drop of a solution of ferri-sulphate, the latter serving to intensify the reaction. Solid proteids are coloured blue under similar conditions of treatment. The reactions have been obtained with all the well-known proteids. In the case of dissolved proteids the limit of the reaction is reached with solutions of 0.03 per cent.

Similar reactions are obtainable with salicylic aldehyde and salicin; also with benzoyl chloride and benzotrichloride.

—C. F. C.

Estimation of Theine in Tea. Arch. de Pharm. **223**, 828.

Hilger recommends the following plan:—10 to 20 grms. of the sample of tea are submitted to three successive treatments with boiling water. A slight excess of basic lead acetate is added to the filtered extract, the precipitate being collected, washed, and decomposed with hydrogen sulphide. The filtered solution, from which the lead has thus been removed, is evaporated to dryness with addition of pure sand, granular marble, magnesia, or chalk. The dried mass is now thoroughly extracted with chloroform in a Soxhlet's apparatus, the residue, left after evaporation of the chloroform, being dried for three hours at 100° and weighed. By repeatedly crystallising the residue from water or alcohol, it may be obtained colourless.

Waage has examined 37 methods proposed or used for the determination of theine, and gives preference to the methods of Mulder, Fricke, Stahl Schmidt, and the one described above, but considers Mulder's method, with some slight modifications, the best. The modified method is as follows:—10 grms. of tea are extracted by four treatments with boiling water, taking altogether four hours' time. The filtered extract, measuring about 2 litres, is evaporated to a syrup, mixed with 2 grms. of pure calcined magnesia and 5 grms. of sand, and, after being thoroughly dried, is submitted to extraction with anhydrous chloroform in a Soxhlet's apparatus. The chloroform is evaporated, a slightly coloured residue being left, which contains fatty and resinous matters. These impurities are removed by

dissolving the residue in hot water and filtering; the filtrate is evaporated to dryness and weighed after being heated to 100° for two hours.

M. Hoffmann and R. Tittelbach also recommend Mulder's method, but the former considers it necessary to treat the aqueous extract with lead acetate to remove tannin and colouring matters as much as possible, precipitating the lead from the filtrate with hydrogen sulphide.—E. B.

On Testing the Purity of Commercial Reagents employed in Elementary Analysis. M. Nencki. Monatsh. Chem. **10**, 233—235.

THE author observes that a pamphlet by Dr. C. Krauch, "On the Testing of Chemical Reagents," omits to notice some of the impurities commonly found in the reagents used in organic analysis. The author finds that lime is a common impurity of cupric oxide, and has in one case found as much as 1.02 per cent. CaO, whilst a quantity of lead chromate obtained from a well-known chemical manufactory contained 13.27 per cent. of lead sulphate. He advocates the testing of these reagents, to avoid misleading results.—G. H. B.

Butter Analysis. L. F. Nilson. Zeits. Anal. Chem. **28**, 175—183.

THE author recommends the following method for determining the amount of volatile fatty acids in butter as being more accurate than the methods of Reichert, Hehner, and Koettstorfer. The clear ethereal solution of the butter-fat, separated from the milk by treatment with ether and potassium hydrate, according to Soxhlet's method, is poured into a beaker, the ether evaporated and the residue dried at 100° C. for half an hour. Whilst the residue is still warm, 2.5 grms. of it are weighed out into a Bohemian-glass flask of 200 cc. capacity, which is then placed in the balance case to cool, and when cold the weight of the butter-fat is adjusted to exactly 2.5 grms., then 5 cc. of a solution of alcoholic potash, made by dissolving 20 grms. of pure potassium hydrate in 100 cc. of 70 per cent. alcohol, are added. The butter-fat is next saponified by gently warming the flask for two minutes or so, and by continuing the heating for a similar length of time, the greater portion of the alcohol is driven off, what remains being removed by a stream of air passed through the flask whilst it is held in boiling water. It is very important that the last traces of alcohol be removed as otherwise ethereal salts are formed in the subsequent operations, and the percentages of volatile fatty acids found are too low. The saponified butter-fat, rendered free from alcohol in the above manner, is dissolved in 50 cc. of distilled water, a few bits of pumice added to prevent frothing, and then 20 cc. of an aqueous solution of pure phosphoric acid, containing 20 per cent. of orthophosphoric acid. The flask is then connected with a tube, about 1 metre in length, bent twice at obtuse angles at distances of 20 cm. and 10 cm. from the ends; the portion nearest the flask has preferably a bulb blown on it, the middle portion is surrounded by a Liebig's condenser. The flask is heated by a small flame and a volume of 50 cc. is distilled over at the rate of 1 cc. per minute. As a certain quantity of insoluble non-volatile fatty acids is always carried over with the steam, it is necessary to filter the distillate and to wash the filter-paper, condenser-tube, and measuring cylinder, with hot water free from ammonia; sometimes ether must be used to cleanse the condenser-tube. The water used for washing is added to the distillate, and the total volume made up to 100 cc.: two drops of phenolphthalein solution are added, and the solution titrated with decinormal potash solution which has been carefully standardised with the same indicator against a decinormal solution of sulphuric acid. The volume of standard alkali required indicates the quantity of fatty acids in the butter-fat. Very reliable results are obtained by this method, the volumes of standard alkali required in a number of tests of the same sample of

butter-fat differing by less than 0.1 cc. But the volatile fatty acids are not entirely separated by one distillation, for further but smaller quantities are obtained by repeating the distillation after adding 50 cc. of water to the residue in the flask. The volume of standard alkali required to neutralise the fatty acids obtained by repeatedly distilling the butter-fat from the morning and evening milk of two cows is shown below:—

	I.		II.	
	Morning.	Evening.	Morning.	Evening.
	Cc.	Cc.	Cc.	Cc.
1	14.27	14.35	16.00	15.92
2	1.35	1.40	1.45	1.51
3	0.58	0.60	0.60	0.58
4	0.35	0.38	0.37	0.39
5	..	0.27

According to Heintz the presence of the difficultly soluble lauric acid renders it impossible to completely separate the soluble from the insoluble fatty acids in Lehner's method, and the author suggests that it is this acid which is only partially distilled at one operation.

The following notes are appended:—

1. The amount of volatile fatty acids contained in colostrum-fat is very low; in two cases where tests were made the volumes of alkali required were respectively 9.27 and 10.0 cc.

2. The maximum amount of volatile fatty acids in butter is reached in from five to seven days after the calving of the cows, remaining constant a short time, then gradually diminishing till the close of the lactation period, at the end of which time the alkali index is rarely less than 12 cc., independently of the season of the year or the fodder.

3. Individuality also bears influence. One cow, for example, from the second month onwards yielded milk containing almost as good a quality of fat as that yielded by other cows at later periods.

4. The alkali index of the fat of normal milk varied between 20.5 and 11.45 cc. Out of 797 tests which were made, only 44 cases were met with in which a lower value than 12.5 cc. was found, and of these 12 were between 11.33 and 11.45 cc. From this it would appear that Reichert's minimum value, namely, 12.5 cc., is too high.

5. In disease the amount of volatile fatty acid is considerably reduced; in one instance, where a cow became ill, the alkali index fell from 16.85 to 10.10 cc.—E. B.

A Modification of Kjeldahl's Method. J. W. Gunning. Zeits. Anal. Chem. 28, 188—191.

The author recommends the use of a mixture of one part of potassium sulphate and two parts of sulphuric acid, instead of sulphuric acid alone, as employed in Kjeldahl's process. The two substances are fused together, forming when cold a semi-solid mass, which can be easily melted and poured from a warm vessel. 0.5 to 1 gram. of the substance to be analysed is heated in a round-bottomed flask of about 300 cc. capacity. Liquids after being acidified are evaporated down almost to dryness. There is considerable frothing at the commencement of the reaction, accompanied by the evolution of at first weak, then stronger, acid. The escape of acid may be prevented by employing an arrangement for condensing the vapours and returning them to the flask. The concentration of the acid in the flask must not be carried too far. As soon as the frothing begins to cease the reaction may be left to go on by itself, the heat, of course, being first regulated. The time necessary to complete the reaction varies, but has never, with the author, exceeded

1½ to 2 hours. Below are some of the results obtained by this method:—

	Weight of Substance Taken.	Percentage of Nitrogen	
		Found.	Calculated.
Bread.....	2 grms.	1.22	..
Milk.....	25 cc.	0.449	..
Uric acid.....	1 gram.	33.3	33.33
Acetanilide.....	1 gram.	10.34	10.37
Morphine.....	0.5 gram.	4.60	4.62
Aniline oxalate.....	..	10.0	10.1

It is pointed out that the success of the determination depends largely on the construction of the distilling apparatus. The author's experience leads him to use a wide (15—20 mm. diameter) distillation-tube, consisting solely of one piece, leading into the vessel which contains the acid. It is worthy of note that a small amount of alkali is extracted from the glass by the condensing water-vapour. This may be prevented by repeatedly rinsing the tube with hot acid before use. Lastly, the author finds that a titration, more exact than with litmus, may be made by the addition to the sulphuric acid used for condensing the ammonia, of a mixture of suitable amounts of potassium iodide and iodate, the liberated iodine being afterwards determined with a standard solution of sodium thiosulphate.—E. B.

Method for the Quantitative Estimation of Fat in Milk. T. Dietrich. Zeits. f. angew. Chem. 1889, 413—414.

The author uses the following method for the determination of fat in milk when many samples have to be treated at the same time:—

A strip of filter-paper about 27 cm. long and 8 cm. broad is tightly wound round a solid wooden cylinder 28 mm. in diameter, thus making a paper shell closed at the bottom and some 5—6 cm. high, like that used by Soxhlet for the determination of fat in feeding-stuffs. A similar shell of cotton wool is now made by winding a strip of prepared cotton wool (such as is used for surgical bandages), of the same dimensions, round a wooden cylinder 20 mm. in diameter. This is rammed into the paper shell, thus lining it with a layer of cotton wool 4—5 mm. thick; the hole in the centre is then loosely filled with cotton wool.

From 15—20 grms. of the milk, which, if sour, are first shaken with a few drops of strong ammonia, to make the liquid homogeneous, are poured into a weighing bottle, weighed, and then poured into the prepared shell, the bottle being weighed again. The shell is then placed upon a small glass dish, and dried at 60°—80°. If the shell has been carefully made, no milk will pass through on to the dish. When total solids are to be determined, the shell is dried till of constant weight; otherwise it is transferred directly to the Soxhlet extractor.

The author finds that his shells, which, on an average, consist of 1.5 grms. of paper and 2—2.2 grms. of cotton wool, contain nearly 0.01 gram. of fat, which must be allowed for in accurate analysis.

The Soxhlet extraction tubes are ground into the condensers, and also into the weighed ether flasks, three of which are supplied to each extractor, thus preventing loss of time.—A. G. B.

New Books.

WATTS' DICTIONARY OF CHEMISTRY. Revised and entirely rewritten by H. FOSTER MORLEY, M.A., D.Sc., and M. M. PATTISON MUIR, M.A., assisted by eminent contributors. In four volumes. Vol. II. London: Longmans, Green, & Co. New York: 15, East 16th Street. 1889.

OCTAVO volume strongly and handsomely bound, price 42s. This, the second volume issued, contains Introduction to the Articles relating to Organic Chemistry by Dr. Morley, List of the Special Contributors, Table of Abbreviations used in the work, and text covering 760 pages, commencing with C (Chenocholic Acid) and ending with I (Indigo). With regard to the strictly systematic and methodic manner of treating a subject this requires to be utilised by frequent practical reference in order to be properly appreciated, and doubtless it will be found to be of the greatest service in the rapid search after facts where time is limited and practical investigation is waiting. For a brief *exposé* of this method given in our notice of Vol. I. see this Journal, 1888, 351. In the present volume, as an example of concise and method treatment of a subject at once of theoretic and technical interest, see article CITRIC ACID, whilst that on CHEMICAL CLASSIFICATION is clearly and ably expounded, withal condensed into a surprisingly brief space. Of considerable importance and value are the articles on Crystallisation, Dissociation, Chemical Equilibrium, Equivalency, Explosion, Fermentation and Putrefaction, and Flame. An important contribution is also that on "Geological Chemistry."

Attention may also be called to the articles on "GLYCERIN" and "INDIGO," which latter concludes the volume. In two cases the observance of the rules as to terminology of late years adopted by the Chemical Society is missed, for we find here the terms "Glycerin" and "Resorein," instead of Glycerol and Resorcinol.

WATTS' MANUAL OF CHEMISTRY. (Based on Fownes' Manual.) Vol. I. Physical and Inorganic Chemistry. Second Edition. (Fourteenth Edition of Fownes.) By WILLIAM A. TILDEN, D.Sc., F.R.S., Professor of Chemistry in the Mason College, Birmingham. London: J. and A. Churchill, 11, New Burlington Street. 1889.

THIS volume commences with a short sketch of the more important Elementary Bodies, the principal Laws of Chemical Combination, and the representation of the constitution and reactions of bodies by Symbolic Notation. The next section contains a description of the Non-metallic Elements, and the more important compounds which they form with one another; and this is followed by a discussion of the general principles of Chemical Philosophy. In this part of the work the Laws of Chemical Combination and Decomposition and the principles of the Atomic Theory are more fully developed. The last section is devoted to the Chemistry of the Metals. Tables of Hydrometer and Thermometric degrees, &c., are given at the end of the book, and a full Alphabetical Index.

The work commences with the author's preface, and then follows a somewhat novel though exceedingly desirable feature, viz., a few "Directions to the Student" in reading and using the book. The TABLE OF CONTENTS follows, then comes the INTRODUCTION, and then the general text, covering 525 pages, and interspersed with 122 effective wood-engravings.

The book is bound in black cloth, is of 8vo. size, and its price is 8s. 6d.

A TEXT-BOOK OF ORGANIC CHEMISTRY. By A. BERNTHSEN, Ph.D., formerly Professor of Organic Chemistry in the University of Heidelberg, &c. Translated by GEORGE MCGOWAN, Ph.D., Demonstrator in Chemistry, University College of N. Wales (Bangor). [The original text specially brought up to date by the Author for this edition.] London: Blackie & Son, 49 and 50, Old Bailey, E.C., Glasgow, Edinburgh, and Dublin. 1889.

The German edition of this work was noticed on its appearance (this Journal, 1888, 405). It has been highly

praised in the German press, and hence an English translation was to be looked for as a desirable consummation. The present book resembles in size and style the German one, and that the accurate expression of the author's views might be secured, Dr. McGowan submitted the proof-slips to Professor Bernthsen's personal revision.

It will be observed that type of two sizes has been employed in the work, in order that the matter which is of the greatest importance, either in itself or for the purposes of a general review, may be readily distinguished.

The treatment of the theoretical matter is, especially in the first half of the book, purely inductive; the isomeric relations of the paraffins, for instance, are first referred to under Butane, and no constitutional formula of any important compound is given without the grounds for it being indicated. The inductive method is also retained even where, as in the case of the theory of the benzene derivatives, the historical development has run on other lines. In accordance with this the class definitions are based not on theoretical but on actual relations. After the Table of Contents, preceded by Author's and Translator's Prefaces, comes a list of "Additions and Corrections," and this is followed by the text, covering 519 pages, and a full Alphabetical Index. For the general sub-division of the subject, we refer to the notice of the German edition (this Journal, 1888, 405). The size is medium 8vo., and the price 9s.

CHEMICAL TECHNOLOGY, OR CHEMISTRY IN ITS APPLICATIONS TO ARTS AND MANUFACTURES. Edited by CHAS. EDWARD GROVES, F.R.S., Editor of the Journal of the Chemical Society, and WILLIAM THORP, B.Sc. With which is incorporated Richardson and Watts' Chemical Technology. Vol. I.—FUEL AND ITS APPLICATIONS. By E. J. MILLS, D.Sc., F.R.S., and F. J. ROWAN, C.E. Edited by C. E. GROVES, F.R.S. London: J. and A. Churchill, 11, New Burlington Street. 1889.

LARGE 8vo. volume, strongly bound in red cloth, price 30s. The work is based upon that of Richardson and Watts, which was itself based on that of Ronalds and Richardson, which was again founded on the German work of Knapp.

It is now announced, and the announcement will be welcomed, that the entire work, of which the present issue forms the first volume, will be divided into sections, of which the most important are—Fuel and its Applications; Lighting; Acids and Alkalis; Glass and Pottery; Metallurgy; Textile Fabrics; Leather, Paper, &c.; Colouring Matters and Dyes; Oils and Varnishes; Brewing and Distilling; Sugar, Starch, Flour, &c.

The present comprehensive work comprises Table of Contents, and a still larger one of Illustrations, which form an important feature of the book, and most of them are splendidly executed. There are no less than 607, and, besides these, five plates, that on page 36 representing Microscopic Sections of Coal, being beautifully executed and coloured.

To give an idea of the extent of the treatment of the subjects, the sub-divisional headings are now given—Wood; Turf or Peat; Coal; Effect of Heat on Fuels; Wood Charcoal; Coke; Distillation of Peat; Artificial or Patent Fuel, Briquettes; Gaseous Combustibles; Liquid Fuel; Minor Fuels; Theory of Heat; Flame; Application of Fuel; Domestic Heating; Heating by Means of Hot Air; Hot-blast Stoves; Heating by Water and Steam; Application of Fuel to Vaporisation; Evaporation; Distillation; Drying; Ovens for baking Bread; Brick and Porcelain Kilns; Furnaces; Gas Furnaces; the practical Effect of Fuel; Analytical Tables of various kinds of Coal and other Fuel. APPENDIX. The General Principles of Coal Washing.

The illustrations represent—I. Boiler Furnaces. II. Briquette Apparatus. III. Calorimeters and Pyrometers. IV. Charcoal Ovens and Apparatus. V. Chemical Furnaces. VI. Coal Washing Apparatus. VII. Coke Ovens. VIII. Evaporating and Distilling Apparatus. IX. Fire-damp Indicators. X. Fire-places, Grates, and Stoves. XI. Furnaces and Cupolas. XII. Gas-fired Boilers. XIII. Gas Producers. XIV. Gas Stoves and Gas Fires. XV. Heating Apparatus. XVI. Heating Gas Retorts. XVII. Hot blast Ovens and Stoves. XVIII. Kilns and Ovens. XIX. Liquid Fuel Apparatus. XX. Mechanical Stokers. XXI. Miscellaneous.

AMMONIA AND AMMONIUM COMPOUNDS. Comprising their Manufacture from Gas Liquor, and from Spent Oxide (with the recovery from the latter of the by-products, Sulphur, Sulphocyanides, Prussian blue, &c.), special attention being given to the analysis, properties, and treatment of the raw materials and fuel products. By Dr. R. ARNOLD. Translated from the German by HAROLD G. COLMAN, Ph.D., M.Sc. London: Sampson Low, Marston, Searle, and Rivington, Limited, Fetter Lane, Fleet Street, E.C. 1889.

This is a small 8vo volume, bound in cloth, price 5s., containing Preface, Table of Contents, text covering 126 pages, and an Alphabetical Index. With the text are interspersed nine wood engravings, and the Appendix, from pages 111 to 120, comprises a useful series of Tables of Specific Gravities of Ammonium Sulphate Solutions, with corresponding percentages of real Sulphate; of Sal-ammoniac Solutions, Caustic Ammonia Solutions (Carius), Sulphuric Acid (Kolb), Hydrochloric Acid and Nitric Acid (Kolb), &c.

A Synopsis of Recent Literature and Recent Patents is finally given.

Trade Report.

(From Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Importation of Oil of Bitter Almonds.

According to a decision of the Imperial Council approved by the Emperor of Russia, Article 250 of the Customs Tariff, which prohibits the importation of oil of bitter almonds, is abolished, and this article will in future pay import duty according to paragraph 2 of Article 144, or 15 roubles 85 copecks gold per pond.

THE NETHERLANDS.

Classification of Articles in Customs Tariff.

According to the *Moniteur Belge*, the following decisions affecting the classification of articles in the Netherlands Customs Tariff have recently been given by the Netherlands Customs authorities:—

Medicinal capsules are free from import duties.

Liquid creoline is assimilated to oils not specially distinguished, and pays, consequently, 0.55 florin per 100 kilogrammes.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220.4 lb. avoirdupois. Franc = $9\frac{5}{16}$ d.

The following decisions affecting the classification of articles in the Swiss Customs Tariff were given by the Swiss Customs authorities during the month of August last:—

Liquid ammonia, in receptacles of wrought iron.—Category 9a. Duty, 7 francs per quintal.

Gun-cotton, for the manufacture of collodion (*collodum-*

wolle) (less explosive, and containing less nitric acid than gun-cotton used as an explosive material).—Category 21. Duty, 40 francs per quintal.

Apparatus of copper for distillation.—Category 105. Duty, 4 francs per quintal. This article is taken out of Category 139.

FRANCE.

Customs Decisions.

Circulars have been issued by the French Customs Department giving the following decisions in regard to the classification of articles in the French Customs Tariff, and to the application of the Customs Law:—

The duty of 5 per cent. *ad valorem* at present applicable, according to the general tariff, on sulphate of quinine imported from abroad, will in future be converted into a specific duty of 250 francs per 100 kilogrammes, without distinction of quality.

Bronze of silicium is assimilated, for payment of duties, to ordinary bronze.

Wine lees declared for temporary admission for the purpose of making cream of tartar and tartaric acid to be re-exported, are to be analysed by the Customs official in order to determine the strength of the lees.

PORTUGAL.

The Customs Treatment of Saccharin.

A despatch, dated the 4th September last, has been received at the Foreign Office from Mr. Petre, Her Majesty's Minister at Lisbon, enclosing copies and translation of a Royal Decree of the 20th August, fixing the import duty on saccharin for consumption in apothecaries' shops in Portugal at 15,000 reis (3*l.* 6*s.* 8*d.*) per kilogramme. Saccharin, where pure or mixed, and any articles of food containing the same, is, according to the decree notified in p. 249 of the September (1888) number of the *Board of Trade Journal*, and subject to the above exception, prohibited to be imported into the continental part of the kingdom of Portugal or into the adjacent islands.

ROUMANIA.

Reduction of Import Duty on Pharmaceutical Preparations and Compounded Medicines.

The *Deutsches Handels-Archiv* for the month of September says that a Roumanian law of the 22nd June last, provides as follows:—

The Customs duty on pharmaceutical preparations or compounded medicines provided for in Article 146 of the "Autonomous" Tariff is reduced from 10 francs to 3 francs per kilogramme.

DUTY ON BUTYRIC ETHER.

A general order has been issued by Her Majesty's Customs to the effect that the Treasury have directed, with reference to the provision contained in the Schedule to the Act 39 & 40 Vict. cap. 35, that a duty of 15*s.* a gallon be charged on butyric ether, upon importation into Great Britain and Ireland, that being the sum which may be taken as equivalent to the duty on the quantity of spirit used in its manufacture.

This duty will be levied on and after the 1st day of October 1889.—*London Chamber of Commerce.*

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

POISONING FROM CANNED PROVISIONS.

The following is an extract from a report to the Foreign Office, dated the 23rd August last, by Captain W. F. Segrave, Her Majesty's Consul at Baltimore, on the subject of canned goods deleterious to health put up in the United States:—

“Commercially all canned provisions that are hermetically sealed are packed in cans made of tinplate, *i.e.*, sheet iron superficially alloyed with tin.

“This article is imported exclusively from England, and is subject to an import duty of one cent per pound. The

average import for the past three years has been 3,600,000 boxes, which paid in duties 3,960,000 dollars. There is no tinplate manufactured in the United States, and yet, with nothing in the tinplate trade to protect, the duty of a cent a pound is still imposed on it.

“One hundred and thirty millions of cans are every year manufactured in Baltimore city alone, and two million pounds of solder are consumed in making them.

“Equal parts of block tin and lead form the best solder, but no doubt a baser description of solder, composed of a larger proportion of lead, is by no means uncommon. A flux of powdered resin, or a much more deleterious flux composed of chloride of zinc, containing free muriatic acid, is applied to the tinned surface to be soldered, and this the unfortunate and dangerous practice is, to apply on the *inside*.

“The use of an acid flux for inside soldering is objected to as a possible source of danger, whereas in cans where resin is used, it is asserted, and no doubt with good reason, that it communicates its taste to the contents of the can.

“To obviate both objections, the law, which is compulsory as well in France as in Germany, should be passed and enforced in this country, to the effect that all cans containing articles of food should be soldered on the *outside*.

“Laudable efforts have no doubt been made by the trade to abolish entirely *inside* soldering, but not as yet with such entire success as they deserve.

“The first danger from the inside surface of solder is the direct solvent action on the lead of an acid fluid, when acid vegetables or fruit are preserved without syrup. The second source of danger is from galvanic action.

“There is one special hermetically sealed product which even in this country and in the trade has a peculiarly evil reputation, and that is the American sardine, in which there is great possibility of danger as at present put up.

“Notwithstanding the label is French, in the well-known yellow and black letters, the contents are not sardines, nor are they put up in ‘huile d’olive pure,’ but in cotton-seed oil.

“Professor Tonry, of this city, states in a report: ‘I have now before me one of these sardine tins, with the solder on the inside, and fully one quarter of the interior surface of the metal eaten away.’

“The fish that were contained in this tin were nearly all eaten by three persons, two of whom were children, and all were taken sick within half an hour after consuming them. The child who had eaten most freely died in 24 hours.

“I made a chemical examination of the viscera and found lead; lead was also found in the oil and remaining contents of the tin. A coroner's inquest was subsequently held, the verdict found being that death resulted from lead poisoning from a sardine tin improperly soldered.”

THE PRODUCTION OF HENEQUEN IN MEXICO.

With reference to the notice on pp. 421—22 of the April number of the *Board of Trade Journal*, a further despatch, dated the 27th August last, has been received from Sir F. C. E. Denys, Her Majesty's Chargé d'Affaires at Mexico, giving the following information on the subject of the production of henequen in Mexico, but more particularly in Yucatan:—

“The great activity in the henequen industry of Yucatan is steadily maintained, the value of the fibre exported during the first seven months of the year amounting to over 7,000,000 dols. (1,005,100*l.*).

“The ports to which it has been chiefly sent are New York, New Orleans, Boston, Havana, Hamburg.

“The small outlay required to make a plantation of henequen, the little care necessary when once the plant has begun to yield, and the immense profits to be derived from the sale of the fibre at the current price, namely, 26 reals the arroba (9*s.* 8*d.* for 25 lbs.), have naturally attracted much attention, and efforts are being made to introduce the plant into other parts of the Republic where the soil offers the necessary features for its successful cultivation.

“The *Diario Comercial*, in a recent number, states that samples of fibre taken from plants grown at Solidad, in the State of Vera Cruz, have been pronounced in New York to be of a superior quality, and to have realised higher prices than the fibre from Yucatan.

"In the neighbourhood of Alvarado, in the same State, the *Diario Comercial* mentions that some 140,000 plants have already been planted, and it is considered probable that the cultivation of henequen, if it prove successful, will here supersede that of cotton, which the dampness of the climate and the ravages of the numerous insects have been rendering less profitable year by year.

"The planters of Yucatan, who are now making large fortunes, may therefore have to contend with a brisk competition in the near future."

THE REIHLEN CHAMPAGNE PROCESS.

United States Consular Reports, May 1889, p. 79.

Champagne, as is well known, is but an ordinary wine charged with carbonic acid gas. The process by which it is made requires time, labour, and skilful manipulation. It begins late in the spring with the wine of the preceding autumn.

In such wine the fungi are still alive and vigorous enough, upon due provocation, to continue the work of fermentation. Older wine, it has been held, could not be employed, because the fungi had, it was thought, become sterilised.

About 2 per cent. of sugar having been put into the bottles they are recorked. Fermentation sets in with production of alcohol and carbonic acid; but there is also at first a muddying of the wine followed by a thick deposit upon the sides of the bottle. Tannin and alum are introduced to loosen this, the bottles are gradually inverted, and at last the whole deposit is collected on the cork. All this is attended with a loss of from 15 to 25 per cent. of the bottles and their contents, so uncontrollable does the pressure become.

The bottles are then "disgorged," that is, the corks are skilfully drawn, the deposit allowed to escape, and sugar brandy and strong wine are added to replace the loss. The champagne is then recorked and is ready for the market.

This involves immense labour, and Herr Adolph Reihlen of Stuttgart set to work to minimise this labour and waste. The method he pursued is based upon the following lines:

In 1833 Schwamm discovered that the deposit thrown down by wine contained countless minute parasitical plants of various orders.

These were recognised as the agent in fermentation, and Reihlen found that these organisms were not confined to wine, but existed throughout the whole vegetable kingdom, and could be induced to settle from the air upon suitably prepared vegetable fibre. Herr Reihlen's apparatus is such that large quantities of wine in one body can be subjected to the fermentation process by means of germs caught from the atmosphere on wood-fibre moistened with sugared water. This fibre is not thrown loosely into the receiver, but is held in a sort of basket, so that it can be withdrawn at pleasure, and with it the sediment which in the old process gave so much trouble.

There being a fixed ratio between the pressure upon the receiver and the advance of the champagne process, it is easy to determine how rapidly the contents can be drawn off as a finished product, and the equivalent of the raw material, wine and sugar, added to make the process continuous.

It was in 1885 that the first bottle of this new champagne was sold. The production is now 6,000 bottles a day. A champagne undistinguishable, it is claimed, from the best French brands is furnished at less than 30 cents. (15*d.*) a bottle.

From the first the new champagne has been in use in the hospitals of Stuttgart and elsewhere, and is pronounced upon authority to be perfectly pure.—C.G.C.

DYEWOODS IN BORDEAUX.

United States Consular Reports, May 1889, p. 84.

There are 15 dye-works in Bordeaux, and the principal dye-wood employed is campeachy wood, imported from Yucatan, the Antilles, Hayti, and South America. Its colour is a vinous red, slightly shading to blue, and produces violet, black, red, yellow, grey, &c., according to the acid substances employed with it.

Yellow wood is also used. The finest comes from Cuba, and is principally used in silk dyeing.

Pernambuco wood or Brazil wood is found near Pernambuco. The price is high, being from 30*s.* to 50*s.* per cwt. owing to which only a small quantity is imported into France. The colour is a positive but beautiful red. Other species, found in the West Indies and Central America, are either reddish-yellow or dark red, which changes to a dark brown when exposed to the air. The derived tints are light red and amaranth, and it is employed to produce a more positive madder-red, and to apply colours on wool, silk, and cotton. The colours, however, are not durable, but can be rendered more so by steaming, or by the addition of gall or sumac. Redwoods are divided into two classes, extractive and non-extractive. The extractive species are imported from Brazil and other parts of America, and includes also the Sapan wood from the East Indies. Chili and Colorado woods are especially esteemed; the colour is pale or brownish-rose. Bahia wood of good quality is violet-red in colour. Sapan wood is pale in colour, but develops a beautiful bright red. Non-extractive woods are sandal, catechou, and camwood. These woods only yield their colouring matter to alkalis. Sandal wood and camwood come from Africa and catechou from the West Indies.

MANUFACTURE AND USE OF ALCOHOL IN FRANCE.

United States Consular Reports, May 1889, p. 176.

On the 14th December 1875 the French Assembly enacted a law providing that all farmers and fruit-growers might distil wines, lees, ciders, plums, and cherries grown on their own property without license or previous declaration and free from all supervision by the revenue officers of the State. This system has now endured for 13 years, and, it is alleged, has led to such serious frauds and such deplorable effects upon the wine market, that it is now demanded that free distillation shall be suppressed and all manufactures of alcohol subjected to uniform control and taxation.

The following facts and statistics have been elicited during the discussion. The native wine product of France has declined from 56,405,000 hectolitres (1,490,153,885 gals.) in 1877 to 24,333,000 hectolitres (642,805,861 gals.) in 1887. The point of interest is to examine how the product of alcohol has varied in relation to the yearly vintage.

While, therefore, the production of alcohol has increased nearly 20 per cent. during the 12 years, the annual distillation of alcohol from wine has fallen from 545,994 hectolitres to 32,758 hectolitres, or 1 gal. in 1887 for each 17 gals. in 1876.

It requires from 7 to 8½ gallons of wine to make one of brandy, so that the whole amount made in 1886—87 could not have exceeded 80,000 hectolitres. Comparing this with the quantity of so-called eogne drunk and exported we obtain some idea of the proportion to which the manufacture from other substances has grown. A large part also of the alcohol made by farmers is used for fortification of wines, and this was especially the case in 1888.

NOTE.—1 hectolitre = 26·417 gallons.

The present law enables low and deleterious grades of alcohol to be made from figs, dates, beets, and other substances, and to be used while warm from the still in fortifying artificial wine made from dried grapes and water. Accordingly it is proposed to suppress the present right of free distillation by cultivators, and introduce supervision by revenue officers of all distillation, reserving to actual wine-growers a privilege of strengthening their vintage to a limit of 2 per cent. free of tax, with alcohol made from wine grown on their own premises.—C. G. C.

MISCELLANEOUS TRADE NOTICES.

DISCOVERY OF PETROLEUM SPRINGS AT ZANTE.

It is announced in the *Revue de l'Orient* that petroleum springs have been discovered at Zante. The quality of the oil having been found very good for lighting purposes, a foreign company has applied for the concession to work the springs, on condition of having a monopoly of the sale for local consumption.

THE DISCOVERY OF A RICH SILVER MINE IN JAPAN.

The *London and China Telegraph* of the 17th September contains the following particulars of the recent discovery of a rich silver mine in Japan:—

South of the city of Furuhiro, in Shiribishi territory, at a point where the river divides into two branches, the Inakura and Ishinosawa, and familiarly known by the name of Futatsumata (two branches), is situated the Furuhiro mine. It was first discovered on July 10, 1885, by three wood choppers. Ten days afterwards they applied for permission to work the mine. A charter was granted in February of the following year, and on March 2 operations were commenced. Scarcity of capital, however, compelled them to abandon the enterprise when only a depth of 13 feet, by 15 feet wide, had been reached. But immediately their charter had expired an officer of the Hokkaido Mining Company sought and obtained the permission of the discoverers to work the mine, and then renewed the charter. Work was recommenced on May 24 this year, under the superintendence of Mr. Kono, an engineer, and the mine has already proved to be of a most fertile character. Thirteen veins have been struck, and it is expected that more will be found. It is also stated that the precious metal lies in the bed of the river. Five pits are now being worked by the company. One of

these, the Shachihoki (Grampus) was found to be very rich in silver when only a depth of 30 feet had been reached. When analysed, the best yields were found to contain $1\frac{1}{2}$ per cent. of silver, middle .4 per cent., and common .2 per cent. silver and .04 $\frac{1}{2}$ per cent. gold. We cannot expect that the output will continue so abundant, but if experienced engineers were employed it would not be difficult to maintain an average of .5 per cent.

ESTABLISHMENT OF A DYNAMITE, SULPHURIC ACID, AND SULPHATE OF AMMONIA FACTORY IN THE ARGENTINE REPUBLIC.

According to the *Bulletin des Musées Commerciaux* there has been established at Zarate, on the Parana, a factory for dynamite, sulphuric acid, and sulphate of ammonia. This establishment is placed under the direction of an Italian engineer. Up to the present the products in question have been imported from Europe.

CANADIAN SUGAR.

The *Canadian Manufacturer* says that "there is no sufficient reason why Canada should not produce all or the greater part of the sugar it consumes, seeing that the soil and climate are eminently well adapted to the growth and cultivation of the sugar beet. Some spasmodic efforts have been made in this direction in the province of Quebec, and indeed there is now a large and well equipped factory there, at Berthier, for the manufacture of sugar from this vegetable. The fact has been satisfactorily established that beets grown in the vicinity of Berthier possess as large an amount of saccharine matter as any grown under the most favourable circumstances in France, Germany, or Austria; and it is equally certain that not only that particular locality, but about all the available lands in Quebec, Ontario, and the North-West are equally well adapted to that industry."

TRADE AND NAVIGATION OF BURMAH.

Ibid., pp. 467—472.

QUICKSILVER IN TUSCANY.

The mining district of Monte Amiata is situated in the province of Grosseto, near the railway station of the same name on the line from Grosseto to Siena.

The Penna mountain consists, beginning at the top, of the following strata:—A circular belt of nummulitic and madreporic limestone of Eocene age; marly manganese shales and limestones of very fine texture and containing calcite in the numerous fissures; marly non-manganese limestones. The principal deposits of cinnabar are found in these limestones in irregularly distributed masses of irregular form; greyish madreporic siliceous beds; small veins filled with very pure cinnabar form an irregular network in these siliceous beds; marls and limestones, similar to alberese limestone, with a network of fissures filled with calcite.

The cinnabar is found in beds and veins. At Siele, the small irregular veins were followed downwards, and at a depth of 360 feet, the most valuable deposits of cinnabar were found in the marly limestones. At Cornacchino the small veins in the siliceous rocks were followed upwards until the deposits were found in the limestones. Usually the clays, impregnated with cinnabar, fill the irregular cavities in the marly limestones. The proportion of cinnabar in the clays is sometimes so small that the ore is only discerned by rubbing the surface of the clay so as to break the particles of cinnabar and produce a red colour. The cavities appear to be all inter-communication, and sometimes contain a breccia of limestone and clay. The clay is sometimes filled with a network of small veins of cinnabar.

The cinnabar is sometimes accompanied by sub-sulphides of mercury (Hg_2S) known as "neri," and native mercury. Iron pyrites and gypsum are associated with the cinnabar in the clays but not in the veins.

Deposits of stibnite (tersulphide of antimony) are found associated with the cinnabar.

The percentage of mercury varies from 2 to 30 per cent. in the mineral, and is concentrated up to 25 or 35 per cent. The ore is washed with rakes in small rectangular boxes. The mineral is then mixed with about 20 per cent. of quicklime and placed in retorts and heated; the mercury which distils over is condensed. The plant appears similar to that used for gas making. One ton of wood is used per ton of mineral, and each operation lasts about seven hours.

The wages paid for 12 hours' shifts (less intervals for meals) are:—Miners, 31 cents; labourers, 25 cents; timberers, 41 cents; waggon-men, 41 cents; women, 12 cents, and an allowance of 4 cents per day to each miner for lamp oil.

The produce of mercury has been:—In 1873, 116 tons of 2,240 pounds; 1876, 111 tons; 1877, 130 tons; 1878, 115 tons, and the production has since gradually increased to 237 tons in 1885.

The cost of production is about 300 dols. per ton or, say, 13 cents per pound, and the selling price in London varies from 37 cents to 50 cents per pound.—*Annales des Mines*.

THE PETROLEUM SITUATION.

Contrary to expectation, the returns from the wells for July show a falling-off in production when contrasted with those of the preceding month. The total number completed was 533, giving a production of 7,022 barrels daily, against 555 wells and a production of 7,650 barrels. The decrease in the number of completed wells is thus 22, and of new production 628 barrels. The average yield from the new wells has fallen to 13·17, which is the smallest yield since December last. A very large number of those drilled proved quite unproductive, and this fact has tended naturally to discourage "wild-cat" ventures. The increased price of certificates has for some time acted as a stimulus to drillers, but the general results are so unsatisfactory that the occupation is by no means a profitable one. Every effort has now been made to bring production in line with consumption; but all these have so far proved unsuccessful, and sanguine operators on the various exchanges confidently predict that in a short time certificates will readily fetch a dollar and a quarter, or even a dollar and a half. There is, however, an almost entire absence of speculation, and as

long as this condition of things exist, the upward movement will be slow. Professor W. T. McGee, of the United States Geological Survey, affirms that the known deposits of coal-oil and natural gas in the United States are not so great as many people suppose. It is impossible, he says, to estimate with any certainty what quantities of oil and gas may be obtained. He is of opinion that it is rather the bituminous matter contained in rocks found all over the country to which America must look in the future for illuminating material. Following the example of oil producers of this country, an effort has been made to combine the candle-makers throughout the States for the purpose of fixing prices and limiting production. The industry at present is not a profitable one, and more, it is said, can be made by selling the raw material than by converting it into candles. Nothing definite has yet been accomplished, but there is reason to believe that an effort will be made in the direction indicated. The candle trade in America is comparatively small, but recently a new factory of some importance has been added, and it is probable that the business will be considerably augmented. It is probable that by the beginning of winter the price of crude scale and candles will be advanced $\frac{1}{2}$ cent per lb. According to the Baku correspondent of a German journal, the Russian petroleum industry is rapidly approaching a crisis owing to the exhaustion of the oil springs. The supply of oil from existing wells is not nearly so great as formerly, and great difficulty is experienced in obtaining a sufficient supply to keep the refineries going. The Messrs. Nobel have been compelled to obtain additional supplies from Bibiebat—a place at a considerable distance from their works. The price of crude oil has been quadrupled during the past month. (See Professor Mendeléeff's Report, this Journal, 1889, p. 753.)—*Oil and Colourman's Journal*.

RUSSIAN PIPE LINES.

Matters are not running smoothly in connexion with the oil wells at Batoum. The fight between the Rothschilds, the owners of the Russian oil wells, and the Russian Government over the right to build a pipe line from the oil wells to the Black Sea has driven a fleet of tank steamships to Philadelphia to secure cargoes of the American product. The dealers in the Russian oils were led to believe that the pipe lines would be built a year ago, and on these assurances a fleet of steamers was chartered, which has been continually added to until the tonnage exceeds the oil output and vessels were forced to go elsewhere for business. The railroad which brings the oil to the seaboard is owned by the Russian Government, which fears if the pipe line is laid the railway will be ruined, as the passenger traffic amounts to nothing.—*Ibid*.

THE RUSSIAN GOVERNMENT AND THE ENGLISH PETROLEUM TRADE.

The Russian Government has despatched to England, to report upon the actual condition of the petroleum trade, M. Gulishambaroff, chief petroleum adviser to the Ministries of Finance and Crown Domains, controlling the Russian petroleum industry. M. Gulishambaroff has edited most of the Russian official literature dealing with petroleum, and is regarded as the leading technical authority in Russia. He ridicules as a canard the statement that the Baku oil supply is decreasing. (See also this Journal, 1889, p. 753.)—*Ironmonger*.

THE ROTHAMSTED EXPERIMENTS.

Sir John Lawes has just issued his annual memoranda of the Rothamsted experiments, bringing the records up to 1888. The tables show that the wheat crop on some plots was above average last year, while barley was below the mark on every plot but one. Where wheat has been grown on the same land every year during 16 years, the average yield is given for the 36 years ending with 1887. The mean yield of two unmanured plots during the period averaged only 13½ bushels per acre; but this is in excess of the average for Russia, America, or India. The highest average yield for the period was 36½ bushels, obtained on a plot to

which was applied a very heavy and costly mixture of nitrogenous, phosphatic, and alkaline manures, and the increase produced, at current prices, would not nearly pay the expense of those fertilisers. The result of applying 14 tons of farmyard manure annually was an average for the 36 years of $33\frac{3}{4}$ bushels, and in this case the increase would pay at current prices, and leave some profit, if the manure were valued at 5s. a ton, without reckoning the increase of straw, but would barely pay if 6s. a ton were allowed for the manure. The use of 275 lb. of nitrate of soda alone gave $23\frac{5}{8}$, the increase of grain paying well for the cost of the manure. It is remarkable that 400 lb. of ammonia salts, a more concentrated manure—in fact, a quantity containing twice as much nitrogen—has given a smaller average yield than the 275 lb. of nitrate of soda during the whole period. The addition of $3\frac{1}{2}$ cwt. of superphosphate raised the yield of the plot receiving the liberal supply of ammonia salts only from $20\frac{1}{4}$ to $25\frac{3}{4}$ bushels; but a further addition of $366\frac{1}{2}$ lb. of sulphate of potash brought the average up to $31\frac{1}{2}$ bushels. In the experiments with barley the mean yield of the unmanured plots averaged $17\frac{3}{4}$ bushels an acre during the 36 years, and the highest average, nearly 49 bushels, was obtained on a plot to which 14 tons per acre of farmyard manure had been annually applied. Other high averages were obtained by means of costly mixtures of nitrogenous

and mineral manures. The use of 275 lb. of nitrate of soda alone brought forth an average of $33\frac{1}{2}$ bushels, and that quantity was increased to nearly 46 bushels by the addition of $3\frac{1}{2}$ cwt. of superphosphate to the nitrate. Each of these two dressings was highly remunerative, the latter especially so. Indeed, no mixture has paid as well as that of nitrate of soda and superphosphate, which happens to be the one most frequently used by farmers. An equivalent to the nitrate, in the form of 200 lb. of salts of ammonia, produced an average of $29\frac{1}{2}$ bushels, and the addition of $3\frac{1}{2}$ cwt. of superphosphate increased the yield to $43\frac{1}{2}$ bushels. These quantities, compared with those just previously mentioned, show that, at Rothamsted, at any rate, nitrate of soda gives better returns in barley than ammonia salts, taking a long course of years, although the latter may prove the better in a wet season. On the other hand, in some experiments with oats, for five years, recorded in the memoranda, but discontinued for some time, ammonia salts gave better results than nitrate of soda; but this was probably because the land was in a very wet condition, which, together with its foulness, led to the discontinuance of the trial.—*Memoranda of the Origin, Plan, and Results of Field and other Experiments conducted on the Farm and in the Laboratory of Sir J. B. Lawes, at Rothamsted.*

BRITISH TRADE IN 1888.

MARGARINE.

The margarine traders do not seem to have seriously felt the pressure of the special enactment by which the name of the article they trade in was legislatively fixed. The imports of butterine under its legal name of margarine was slightly lower than in 1887, and this may have been due to the vigilance of public officers in strictly enforcing the Margarine

Act in all cases of infringement, but towards the close of the year demand was brightening after 12 months of sluggishness and doubtfulness.

MARGARINE IMPORTED AND RE-EXPORTED.

	1886.	1887.	1888.
Imported:			
Quantity, cwt.	886,573	1,273,095	1,138,174

Value £.....	48,533	53,482	50,614
Average value per cwt.....	£2.76	£2.41	£2.47

The enterprise of Dutch manufacturers has enabled them so far to maintain supremacy in this article of increasing use and widespread consumption. How much the trade is monopolised by Holland will be seen from comparing the above total figures with the appended statement of imports from that country.

From	1886.		1887.		1888.

LARD.

Owing to the extra alertness of the officers charged with carrying out the Adulteration of Foods Act, there was considerable disturbance in the lard trade. This disturbance was not very limited in its extent. Prosecutions were fairly general throughout the country, and retailers were awakened to their responsibility in vending articles of consumption. This, of course, recoiled upon the manufacturers, and in view of the desire on the part of the Legislature to protect the consumers' interests to a greater extent than hitherto, approval will far outweigh the objections to the strict enforcement of the laws fulfilling this desire. It would appear that cotton-seed oil—an ingredient which is known to play a very prominent part in the manufacture of of "olive" oil also—has been the principal ingredient introduced into concoctions labelled "lard." "Lardine" is the name attached to a mixture of hogs' fat and cotton-seed oil; and as the Americans claim that the latter ingredient is not injurious to health, it is probable that we may have to add this new mixture to the list of articles of commerce. Since "butterine" was thought too distinct an imitation of "butter" to be devoid of any taint of deception, it will be interesting to see whether "lardine" will be permitted.

LARD IMPORTED AND RE-EXPORTED.

	1886.	1887.	1888.
Imported:			
Quantity, cwt.	8,6324	906,100	883,469

Value £.....	129,972	28,229	115,989
Average value per cwt.....	£1.91	£1.73	£2.00

It is due to the American Congress to state that a bill was introduced to stamp out adulteration, but it was not passed. The result of the attempt was beneficial, however, and less call for cheap and doubtful goods has probably had its proper effect in restricting their production. Prices for "pure lard" rose considerably, and the United States seem to have participated in the *bona fide* trade, for the imports therefrom in 1888 amounted to 832,126 cwt., compared with 831,790 cwt. in 1887, whilst the value in 1888 was 1,705,339*l.*, against 1,459,055*l.* in 1887. The average value in the first-named year was 2.04*l.* per cwt., and in 1887 only 1.75*l.* per cwt., or a rise of over 16 per cent.

DYESTUFFS IMPORTED AND RE-EXPORTED.

	1886.	1887.	1888.

Total £.....	1,243,991	1,231,592	1,119,266

These figures show an advance in values of dyestuffs imported, both over 1887 and 1886, and lend strength to the other facts adduced in support of the comparative prosperity in 1888 of the industries they supply. Cochineal, it will be observed, is fast disappearing, having decreased in quantity by 50 per cent. compared with 1886, without any like appreciation of value, showing that demand has fallen off almost concurrently. The net receipts of indigo betray an improvement, and coal-tar dyes still progress. We understand, however, that a large proportion of the latter are re-exported. The monthly returns do not register the movement, but the British aniline dye manufacturers are aware that they have not had to compete with such supplies in the home market as would appear from the imports to have been the case.

CHEMICAL TRADES.

The chemical trades are advancing in importance annually, and the enterprise of those concerned in them bids fair to keep pace with the established foreign competition in this division. There was an increased business done last year both in importations of foreign goods and in exports of British chemicals and drugs. Altogether the prices realised were on a somewhat low level, but this gave hope for the future that the bottom had been reached in the main articles, so that the outlook was bright. In alkalis the importations decreased in quantity, but increased in value compared with 1887; whilst in British alkalis exported the position was reversed of a larger quantity being sent out at a decreased value on the preceding year. The returns show the following total results for—

FOREIGN CHEMICALS IMPORTED AND RE-EXPORTED.

—	1886.		1887.		1888.	
Imported:	Cwt.	£	Cwt.	£	Cwt.	£
Alkali	78,797	55,602	61,172	47,809	56,753	50,567
Brimstone	636,596	157,917	661,153	157,188	782,854	175,946
Nitrate of soda	1,097,725	744,513	1,796,802	832,541	2,053,282	984,894
Saltpetre	271,322	240,186	333,918	261,526	353,691	300,663
Various	1,281,275	..	1,316,853	..	1,310,914
Total £	2,482,793	..	2,615,917	..	2,822,084
Re-exported:						
Saltpetre	24,575	21,116	32,856	28,924	42,335	35,679
Various	149,078	..	283,625	..	392,221
Total £	170,224	..	312,549	..	337,900
	..	2,312,569	..	2,303,368	..	2,484,184

Attention may be directed to the fact, that although there was a rise on the importations there was also an increase in the re-exportations, leaving an extension of net receipts of 180,816*l.* value. The average prices calculated on these figures show:—

AVERAGE PRICES PER CWT. OF SUNDRY FOREIGN CHEMICALS.

—	1886.	1887.	1888.
Imported:	£.	£.	£.
Alkali	11.11	14.90	17.82
Brimstone	4.90	4.75	4.47
Nitrate of soda	9.94	9.62	9.59
Saltpetre	17.72	17.21	17.00

The returns of exports of British chemicals are satisfactory as to the values, except in regard to alkalis, as there were advances in the total values declared for bleaching materials and preparations, chemical manures, and the wide

range of articles included under the head of chemicals "unenumerated." For all these goods the statistics tell their own tale of steady growth during the last three years, in bulk if not in value:—

BRITISH CHEMICALS EXPORTED.

—	1886.		1887.		1888.	
Exported:	Cwt.	£	Cwt.	£	Cwt.	£
Alkali	6,242,800	1,788,978	6,161,960	1,742,771	6,347,339	1,638,861
Bleaching materials	1,550,400	502,919	1,578,300	502,961	1,694,146	615,724
Manures (chemical)	1,614,643	..	1,640,919	..	1,846,536
Various	1,976,640	..	2,191,915	..	2,405,104
Value £	5,881,089	..	6,168,566	..	6,506,225

As to average prices we gather the following details:—

AVERAGE PRICES PER CWT. OF BRITISH CHEMICALS EXPORTED.

—	1886.	1887.	1888.
Exported:	£.	£.	£.
Alkali	5.73	5.81	5.16
Bleaching material	6.48	7.57	7.67

The manufacturing activity of other countries is to a certain extent evidenced by the figures relating to bleaching materials, for which the returns of exports have been so continuously extending in quantities and values.

As chemical manures form a prominent item in a fore-going table, it is interesting to show the extent of the trade in:—

FOREIGN MANURES IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Guano and bones, value £.....	828,747	439,810	513,114
Re-exported:			
Guano only, value £.....	50,930	96,856	42,952
Net imports £.....	777,817	342,954	470,162

With the development of scientific agriculture, the prospect for chemical manure manufacturers is brighter than that of traders in the other forms of fertilisers. The position of drugs in the total foreign commerce is not a very high one. In 1888 there was a spurt on the part of foreign introductions, after a decline in the preceding 12 months on the trade of 1886, as shown below:—

FOREIGN DRUGS IMPORTED.

—	1886.	1887.	1888.
Imported:			
Value £.....	670,525	650,440	887,422

On the other hand, British drugs sent abroad have in the last three years made steady headway. The official statistics disclose the annexed register of exports in the last three years, by which it will be seen that the clearances in 1888 outwards, exceeded those in 1886 by over 15 per cent. in value:—

BRITISH DRUGS AND MEDICINAL PREPARATIONS EXPORTED.

—	1886.	1887.	1888.
Exported:			
Value £.....	814,213	869,083	938,125

An important development may be anticipated in this branch, too, from the favourable reception given, and concessions made to the demands of chemical traders for greater facilities for manufacturing in bond for export. One concession on the part of the Customs and Inland Revenue effected a definite result in 1888. Owing to the fact that the Germans had been able, and Britishers unable, to clear "waste tea" from the bonded warehouses without payment of duty, the manufacture of caffeine had been practically confined to our neighbours across the North Sea. The advantage thus given to foreigners having been demonstrated to the satisfaction of the financial departments, permission was granted to British manufacturers to clear such waste tea "free of duty" after it had been rendered unfit for domestic consumption as tea. A new industry thus sprang up, and its effect on the manufactories abroad was startlingly sudden, by reason of the reduction in price effected, even before the marketing, on any large scale, of the home-made article.

OILS.

Oils form an increasingly important factor in the aggregate home and foreign trade. On the two largest branches of cotton seed and flax and linseed imported for treatment there was a considerable enlargement both of quantities and values last year:—

COTTON, FLAX AND LINSEED, AND RAPE SEED IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Cotton.....	£ 1,498,011	£ 1,543,645	£ 1,646,349
Flax and linseed.....	4,266,998	4,296,868	4,800,016
Rape	566,698	457,969	448,254
Total	6,271,707	6,298,512	6,894,619
Re-exported:			
Flax and linseed	362,716	142,713	279,754
Rape	115,808	37,249	56,769
Total	478,524	179,962	336,550
Net imports	5,793,183	6,118,550	6,558,069

Linseed was taken to the extent of beating any previous register of imports, and the British East Indies were the principal participators in sending forward greater quantities. Owing to the shortness of the Egyptian crop, remunerative business was done in cotton seed; but with rape the demand was desultory in the first half of the year, with an improvement in the latter six months. Home crushers are evidently making way, although they have not yet succeeded in permanently decreasing the supplies of oils taken from abroad of this kind, since they amounted to 16,311 tons in 1888, compared with 15,609 in 1887, and 16,327 tons in 1886. The total value of all oils was as follows:—

FOREIGN OILS IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported.....	£ 6,049,148	£ 6,088,246	£ 6,432,871
Re-exported.....	786,968	761,635	967,602
Net imports	5,263,080	5,326,611	5,465,179

Petroleum stands in this total for 2,558,753*l.*, and more detailed figures will be found on pp. 165—67. Of some other divisions of the imports the following statistics are available:—

COCOANUT, PALM AND SEED OILS, AND TURPENTINE IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Quantity, cwt.	1,771,212	1,851,684	1,838,429
Value £.....	2,041,000	2,041,579	2,130,172
Average value per cwt.....	£1'15	£1'10	£1'15
*Re-exported:			
Quantity, cwt.....	587,534	601,881	791,555
Value £	649,788	626,021	820,330
Average value per cwt.....	£1'10	£1'04	£1'03

* Cocoonut and palm oil only.

In addition to the quantities declared in cwt., we have also to note 18,580 tons of olive and 16,861 tons of train, blubber, and sperm oils imported of the value of 674,472*l.* and 323,579*l.* respectively in 1888. Although the imports of foreign seed oil maintained their position in 1888, the dealers in the home-made article had a satisfactory export trade, on which the increase in 1888 was 3,314 tons compared with 702 tons only on the imports of foreign seed oil.

BRITISH SEED OIL EXPORTED.

—	1886.	1887.	1888.
Exported:			
Quantity, cwt.	1,413,520	1,501,960	1,568,240
Value £.....	1,502,346	1,567,646	1,594,501
Average value per cwt.....	£1'06	£1'04	£1'01

TALLOW.

Tallow dealers had a brisk year, demand being so active in the early part that large arrivals were subsequently the cause of a slight fall in prices. Towards the end of 1888, too, the demand again became great, and much buoyancy in the trade was noted, English varieties maintaining a very steady position, as supplies were far from abundant. Receipts from Russia nearly doubled, rising from 6,532 cwt.

in 1887 to 11,434 in 1888, but this was not one-third of the imports therefrom in 1886, which stood at 35,579 cwt. Australasia sent 559,495 cwt. in 1888, and 416,658 in 1887; the Argentine Republic 80,147 cwt. in 1888, and only 22,209 cwt. in 1887, whilst the United States sent less in 1888 than 1887 by the difference between 311,022 cwt. and 329,367 cwt.

TALLOW AND STEARINE IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Quantity, cwt.	1,010,396	895,658	1,116,610
Value £	1,296,552	1,071,028	1,192,595
Average value per cwt.	£1.28	£1.20	£1.25
Re-exported:			
Quantity, cwt.	218,416	319,044	315,653
Value £	250,598	351,143	367,597
Average value per cwt.	£1.14	£1.13	£1.16

SOAP.

Connected with these imports, it is interesting to observe the progress of British soap exports, whilst in the home market consumption advances under the stimulus of lower prices and improved production.

BRITISH SOAP EXPORTED.

—	1886.	1887.	1888.
Quantity, cwt.	426,904	452,751	498,155
Value £	416,710	452,244	481,890
Average value per cwt.	£1.01	£1.00	£0.96

CANDLES.

Allied both with these and with imports of oils from tropical climes is the manufacture of candles, in which home producers had not much satisfaction from the export trade, although the magic quantity of 10 million lb. was passed in 1888.

BRITISH CANDLES EXPORTED.

—	1886.	1887.	1888.
Exported:			
Quantity, cwt.	80,063	83,153	96,565
Value £	201,919	180,872	199,174
Average value per cwt.	£2.52	£2.17	£2.06

Foreign competition is extending in this branch, with the result that prices are cut very fine. The significance of this could not be made plainer than the above average and total values, from which it will be seen that over 16,000 cwt. more were supplied in quantity in 1888 than in 1887, for 2,100l. less value.

PAINTERS' COLOURS.

In colours and materials for painters the following foreign trade was done:—

BRITISH PAINTERS' COLOURS AND MATERIALS EXPORTED.

—	1886.	1887.	1888.
Value £	1,266,103	1,317,684	1,447,750

TANNING SUBSTANCES IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Bark, cwt.	390,793	346,583	339,985
Value £	173,066	147,101	135,018
Average value per cwt.	s. 8.85	s. 8.19	s. 7.95
Cutch and gambier, cwt.	567,380	545,160	562,700
Value £	654,438	658,364	701,731
Average value per cwt.	£1.15	£1.20	£1.25
Madder, &c., cwt.	21,325	19,397	15,034
Value £	26,710	24,267	19,292
Average value per cwt.	£1.25	£1.24	£1.28
Valonia, cwt.	679,900	591,660	690,310
Value £	480,742	324,194	457,634
Average value per cwt.	s. 11.14	s. 11.28	s. 13.24
Total £	1,331,956	1,253,869	1,316,675
Re-exported:			
Cutch and gambier, cwt.	263,840	192,400	187,380
Value £	255,145	251,818	249,860
Average value per cwt.	£1.25	£1.30	£1.33

CAOUTCHOUC.

The rubber trade, which is also to an extent dependent on the electrical industries prospering, is shown below to have taken a decreased import in 1888 of both caoutchouc and gutta-percha, there being a rise in values of both, and in the latter by itself of about 50 per cent. :—

CAOUTCHOUC AND GUTTA-PERCHA IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Caoutchouc, cwt.	192,518	235,539	218,171
Value £	2,202,746	2,682,515	2,529,436
Average value per cwt.	£11.44	£11.38	£11.59
Re-exported:			
Caoutchouc, cwt.	109,416	116,570	127,814
Value £	1,281,499	1,311,613	1,335,835
Average value per cwt.	£11.71	£11.51	£10.45
Net imports £	921,247	1,370,902	1,193,601
Imported:			
Gutta-percha, cwt.	10,697	24,145	22,483
Value £	269,808	156,563	181,660
Average value per cwt.	£6.63	£6.48	£8.43
Re-exported:			
Gutta-percha, cwt.	11,525	8,821	8,372
Value £	75,159	61,716	62,372
Average value per cwt.	£6.54	£6.99	£7.45
Net imports £	194,349	144,847	119,288

The crop of Para rubber was an exceptionally heavy one, and its total may not be reached in 1889, when a rise in prices may again be expected if the United States, which principally cleared off the largely-augmented supplies in 1888, maintains its consuming power at the same level. We are unable to gauge the value of the rubber boot and

shoe trade here, but a large amount is used up by Americans in this way alone. They too are far more advanced than Britishers in the use they make of electricity for all purposes. British rubber manufacturers for exports did fair business, having an increased value to their account in the returns:—

BRITISH CAOUTCHOUC MANUFACTURES EXPORTED.

—	1886.	1887.	1888.
Exported:			
Value £	971,108	1,070,311	1,143,104

PAPER.

Taking the imports of raw materials as a basis on the one hand and exports of British goods on the other, the indications for the British paper, stationery, and printing trades in 1888 are as distinctly encouraging as those of any other trade in the whole returns. In only a single instance, that of British rags exported, has a decrease to be noted. The foreign raw materials imported for paper-making are here covered for three years, the increased use of wood pulp demanding attention.

PAPER-MAKING, FOREIGN RAW MATERIALS IMPORTED.

—	1886.	1887.	1888.
Imported:			
Rags, tons	36,852	38,223	41,404
Value £	458,409	465,932	470,833
Esparto and other fibres, tons.	194,646	199,750	247,936
Value £	996,723	966,380	1,265,515
Pulp of wood, tons.....	..*	79,543	110,040
Value £*	511,450	677,968
Total tons	231,498	317,516	399,380
„ Value £	1,455,222	1,937,762	2,414,516
Average value per ton.....	£6.28	£6.10	£6.05

* Not separately stated.

Demand must have been very active to have encouraged the large imports, too, of the manufactured articles, as the net value retained was in excess of 1886 by 271,714*l*.

FOREIGN PAPER IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Quantity, cwt.	1,515,197	1,701,254	1,922,283
Value £	1,491,903	1,587,876	1,767,145
Average value per cwt.....	£0.98	£0.93	£0.91
Re-exported:			
Quantity, cwt.	71,771	66,135	87,248
Value £	89,848	77,780	93,376
Average value per cwt.....	£1.25	£1.16	£1.07
Net imports	1,402,955	1,510,696	1,673,769

The good features are not limited to the foreign articles of which the imports are low-valued. Whereas there was a decrease in the average value of foreign rags imported as raw materials, those of British origin exported experienced a rise in price sufficient to make the gross value exceed that of 1887 by over 2,000*l*., whereas the aggregate quantity was less by 862 tons.

PAPER-MAKING, BRITISH RAGS FOR, EXPORTED.

—	1886.	1887.	1888.
Exported:			
Quantity, tons	49,255	59,199	58,337
Value £	388,406	458,267	460,335
Average value per ton.....	£7.78	£7.74	£7.89

GLASS.

In the glass trade we continue to be under the sway of foreign producers, a state of things probably due to the inclusive system of syndicates which govern the industry, and some of which work in conjunction with producers in the United Kingdom. The extension of building operations caused a further demand, and the imports increased in quantity and in prices compared with 1887 and 1886.

FOREIGN GLASS IMPORTED AND RE-EXPORTED.

—	1886.	1887.	1888.
Imported:			
Quantity, cwt.....	1,473,275	1,662,336	1,786,202
Value £	1,546,267	1,678,906	1,906,325
Average value per cwt.	£1.05	£1.01	£1.06
Re-exported:			
Quantity, cwt.	175,355	195,674	200,208
Value £	152,686	166,131	174,789
Average value per cwt.....	£0.87	£0.85	£0.87

Although our imports are nearing two millions sterling per annum, our exports are also augmenting, and last year passed 1,100,000*l*. in value. Bottles contribute more than one-half the quantity and nearly one-half the value comprised in the appended figures under "other kinds," having been in 1886, 750,515 cwt. (114,537*l*.); in 1887, 826,409 cwt. (390,585*l*.); and in 1888, 864,888 cwt. (406,088*l*.).

BRITISH GLASS EXPORTED.

—	1886.	1887.	1888.
Exported:			
Plate glass, square feet.....	4,402,132	4,697,143	4,348,716
Value £	240,367	262,680	261,013
Average value per 100 square feet	£5.46	£5.59	£6.00
Other kinds:			
Quantity, cwt.....	1,005,424	1,003,694	1,198,145
Value £	730,010	758,349	848,646
Average value per cwt.....	£0.72	£0.69	£0.71

CEMENT.

Cement exports were more for the whole year by 105,000 tons than in 1887, and by 138,000 tons compared with 1886, but prices realised declined. The chief foreign customers for this article are the South American and United States, where the public works in progress of execution maintain a good demand. Under the rise in freights, the business was somewhat checked at the close of the year, but the prospect was one of increased demand. Australasia, of British possessions, takes the largest quantity of this article.

BRITISH CEMENT EXPORTED.

—	1886.	1887.	1888.
Exported:			
Quantity, tons.....	425,880	506,090	611,328
Value £	802,052	982,776	1,160,419
Average value per ton.....	£2.02	£1.94	£1.89

More than half the value is contributed by the under-mentioned countries:—

—	1886.	1887.	1888.
	£	£	£
United States	204,716	392,543	354,121
Australasia	174,002	149,759	212,718
Argentine Republic.....	64,515	51,568	110,261

BUSINESS WITH FOREIGN COUNTRIES.

The gross value of the divisions of our business with foreign countries is shown below, taking the monthly trade returns as the basis:—

—	1886.	1887.	1888.
	£	£	£
Imports	349,381,086	361,935,006	386,582,626
Exports.....	212,432,754	221,414,186	233,733,937
Re-exports.....	56,234,263	59,348,975	64,613,447
Total, including re-exports	618,048,103	642,698,167	684,929,110
Total, excluding re-exports	561,813,840	583,349,192	620,315,663

The complaints of small margins, which from an exhaustive examination of trade reports we know to be general, are warranted by these tables, summary as they may be. "The Economist" index number betrayed a falling off for the end of 1888 contrasted with the beginning, and the same authority asserts, from calculations effected on usual bases, that the volume of business also did not progress at the same rate in 1888 over 1887 as did 1887 over 1886. The

figures supplied by this source for the last five years show the following to have been the fluctuations in volume of our foreign trade in the last five years:—

FOREIGN TRADE.—VOLUME.			
—	Net Imports.	Exports.	Imports and Exports.
	Per Cent.	Per Cent.	Per Cent.
1888	+ 3'42	+ 4'64	+ 3'91
1887	+ 5'07	+ 4'80	+ 4'93
1886	— 0'37	+ 5'33	+ 1'94
1885	+ 3'28	— 3'84	— 0'26
1884	— 2'81	— 1'14	— 1'23

At the same time "the Economist" statistics incline to the support of rising prices, and there are adduced the appended figures showing the average rise or fall in prices of imports and exports over five years in justification of this cheerier view of things:—

FOREIGN TRADE.—PRICES.			
—	Net Imports.	Exports.	Imports and Exports.
	Per Cent.	Per Cent.	Per Cent.

REVIEW OF THE PETROLEUM INDUSTRY.

1. Statistics of the Petroleum Trade of the United Kingdom for the year 1888, from the Annual Petroleum Circular of Messrs. Mordant Bros., and a return compiled by Messrs. Henry Funck & Co.

The prominent features of the trade have been the large increase in the importation of Russian petroleum, and the development of the tank system of ocean transport.

The shipments of petroleum oil from the United States and Russia to the United Kingdom for the past six years have been as under:—

—	American.	Russian.	Total.
	Barrels.	Barrels.	Barrels.
1883	1,329,004	502	1,329,505
1884	927,919	17,078	944,997
1885	1,367,729	79,149	1,446,879
1886	1,363,801	16,814	1,410,615
1887	1,444,350	188,461	1,632,811
1888	1,286,118	549,126*	1,835,244

* Of this quantity, 528,793 barrels were shipped in bulk in tank steamers, the amount being stated in barrels in accordance with the practice of the trade.

The destinations of the shipments in 1888 were as follows:—

Ports.	American.	Russian.	Total.
	Barrels.	Barrels.	Barrels.
Belfast	21,990	2,500	24,490
Barrow-in-Furness	..	14,492	14,492
Bristol	132,980	7,058	140,038
Cork	2,750	..	2,750
Cardiff	12,014	..	12,014
Dublin	38,014	7,100	45,114
Exeter and Exmouth	31,029	..	31,029

The monthly deliveries of petroleum oil from the London public wharves were:—

—	January.	February.	March.	April.	May.	June.	July.
	Barrels.	Barrels.	Barrels.	Barrels.	Barrels.	Barrels.	Barrels.
1886	74,005	62,399	65,802	35,672	31,922	21,818	20,111
1887	96,503	56,026	55,280	38,514	38,792	22,616	23,415
1888	78,408	69,964	59,703	52,622	29,082	25,114	37,758

—	August.	September.	October.	November.	December.	Total.
	Barrels.	Barrels.	Barrels.	Barrels.	Barrels.	Barrels.
1886	50,885	59,666	60,316	81,095	68,735	636,936
1887	43,922	60,035	89,400	78,630	87,956	691,659
1888	39,110	52,391	98,215	82,493	111,522	731,392

The average price has been:—

—	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
	d.	d.	d.	d.	d.	d.	d.	d.	d.	d.	d.	d.

Waterford	11,800	..	11,800
	1,286,118	549,126	1,835,244

The aggregate importation of American and Russian petroleum oil into London for the past six years has been:—

	Barrels.
1883	714,753
1884	325,101
1885	688,616
1886	700,184
1887	708,554
1888	849,587

The stock in London on the 1st January was as follows:—

	Barrels.
1886.....	98,483
1887.....	98,124
1888.....	70,519
1889.....	92,148

II.—STATISTICS OF THE PETROLEUM TRADE OF THE UNITED STATES, 1888.

	Barrels (of 42 American gals.).
Production of crude petroleum	16,259,975
Shipments of crude petroleum from the oil regions	26,470,654
Stocks of crude petroleum, Dec. 31st, 1887	28,354,299
Stocks of crude petroleum, Dec. 31st, 1888	18,595,471
Approximate consumption of crude petroleum for home trade	10,000,000
Approximate consumption of crude petroleum for export trade	16,000,000

Shipments of crude petroleum and its products from the United States (New York, Philadelphia, Baltimore, and Boston) during 1888, from the annual report of Messrs. Ibeling, Niemeyer, and Wessels.

Crude petroleum	{ 1,233,778 barrels. 1,138,428 cases.
Petroleum oil	{ 5,639,170 barrels. 13,432,867 cases.
Petroleum spirit	{ 264,262 barrels. 25,722 cases.
Petroleum residuum	15,062 barrels.

Of the crude petroleum and petroleum oil a considerable proportion was shipped in bulk.

III.—STATISTICS OF THE PETROLEUM TRADE OF RUSSIA.

Approximate Unofficial Estimates for the Year 1888.

Crude petroleum produced in the Balak-hany and Bibi-Eibat oil fields	Pounds. 175,000,000
Kerosene manufactured	52,000,000
Of the kerosene there were transported:—	
By rail from Baku to Batoum	31,000,000
By sea from Baku to the Volga	21,000,000
Of the kerosene transported by rail to Batoum, there were shipped:—	
To Odessa, about	3,000,000
Abroad, about	28,000,000
Of the kerosene shipped from Baku to the Volga, there were consumed in Russia about	16,000,000
And there were exported via the Austrian and German frontiers, or Baltic ports, about	5,000,000
Of lubricating oils the export exceeded	2,000,000
Of petroleum residuum the consumption in Russia as fuel probably amounted to	50,000,000

The United States and Russia continue to be the only countries exporting petroleum, though Canada and Galicia produce a large amount for home consumption, and in Scotland about half a million barrels of mineral oil are annually manufactured from shale. Several promising petroleum fields exist in India in addition to the well-known deposits in Burmah, and in many other countries petroleum occurs in considerable quantities, but as yet these sources have either been neglected or have not been so far developed as to become of commercial importance.

THE JUTE TRADE.

Although samples of jute were exhibited in this country in the beginning of the century, it was only about the year 1823 that sufficient quantity was received here to enable it to be tested as a fibre suitable for spinning purposes. For some years importers of jute met with little encouragement, as spinners, manufacturers, and consumers were all prejudiced against it, and it was only about the year 1835 that any progress was made in establishing the fibre as one suitable to be made into cloth. After that date, however, it began to be more freely used in Dundee, and year by year the consumption of that material there has steadily and rapidly increased. About 15 years ago the manufacture of jute was commenced on the Continent, and now in every country in Europe there are jute-spinning and weaving factories. Most of the jute is sent from London to these countries, but the direct shipments from Calcutta are getting larger every year.

For many years jute was used in combination with other fibres, principally hemp and flax, but now it is almost entirely used alone, the principal products of the fibre being Hessians, a light material used for packing and many other purposes, and the heavier fabrics, sackings and bagging. There is also a considerable quantity manufactured into carpets, rugs, table-cloths, and curtains, the jute being easily dyed, and made to produce very bright colours.

Most of the manufacturers in this country and on the Continent have machinery for finishing and packing their own goods, but in addition there are eight calendering works in Dundee, that finish, mangle, make up, and pack jute goods. They also cut up the cloth and make it into sacks or bags when required. Many of the manufacturers of carpets dye their own yarns, but there are four works in Dundee that only dye yarns. There are also 12 bleach works in the county of Forfar, many of which bleach or semi-bleach jute yarn and cloth, but the bulk of their business is bleaching flax yarns.

A considerable portion of the machinery used in the process of jute manufacture is made in Dundee and its neighbourhood, but it is also made in Leeds, Belfast, and other places.

METALS AND MINERALS OF THE UNITED KINGDOM.

STATEMENT SHOWING THE QUANTITIES OF METALS OBTAINABLE FROM ORES PRODUCED IN THE UNITED KINGDOM IN 1886 AND 1887, WITH THE TOTAL OFFICIAL VALUE AND THE AVERAGE VALUE PER TON.

Metal.	1886.			1887.

—Year Book of Commerce.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

14,736. G. F. Redfern.—From W. P. Abell, British Guiana. Centrifugal machines. September 18.

14,786. E. de Pass.—From G. Lelièvre. Means for raising, conveying, and projecting liquids by compressed air. September 19.

14,865. C. W. Guy. Improvements in and relating to evaporating apparatus, also applicable to steam generators. September 20.

14,891. T. Parker. See Class XI.

14,951. E. Ackroyd.—From E. Ackroyd, New Zealand. Improvements in filters. September 23.

14,958. J. Hodgkinson. Mechanical stokers, and apparatus connected therewith. September 23.

15,124. R. C. A. Bantfield.—From C. Liude, Germany. Method and means for refrigerating and drying air. September 25.

15,229. P. Colligan. Apparatus for gauging liquors whilst boiling. September 27.

15,432. R. Marsden and J. Pickard. Improvements in condensers. October 1.

15,599. C. Thompson. Improvements in gas furnaces. October 4.

15,867. C. Thompson. Improvements in gas furnaces. October 9.

16,010. J. Fitton. An anti-corrosion composition for retorts used for evaporating acids and other similar purposes. October 11.

16,037. H. H. Lake.—From C. A. Catlin, C. S. Sweetland, and R. Cox, United States. An improved method of charging liquids with gas. Complete Specification. October 11.

16,063. G. Rose. Apparatus for pumping, raising, or forcing liquids, air, or gases. October 12.

16,099. P. Nézeraux. Centrifugal pumps, compressors, and blowers. October 12.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

11,613. I. S. McDougall and J. T. McDougall. See Class XIX.

15,229. J. Newton and D. A. Quiggin. Coiled tubular heating or cooling surfaces for apparatus for condensing steam, heating or cooling fluids, and evaporating. September 25.

15,495. J. Hilton, E. Jackson, and G. C. Hilton. Furnaces for economising fuel and consuming smoke. October 9.

16,372. H. Paplett and J. L. Rigg. Apparatus for distillation and liquefaction of condensable gases. October 16.

16,443. L. Johnson and J. Powell. Apparatus for charging furnaces or for analogous purposes. September 25.

16,535. T. Gaunt and E. H. Clapp. Apparatus for evaporating, distilling, refining, or concentrating liquids. October 2.

16,726. J. Cooper. Blast or air supply pipes for gas producers and other furnaces. October 16.

17,425. J. Buchanan. Fluid pressure and vacuum gauges. September 25.

17,564. Sir L. Bell, Bart. Evaporating brine and other solutions. October 9.

18,085. A. E. Tavernier and E. Casper. An improved pressure gauge. October 16.

18,177. H. R. Gregory and G. MacDonald. Manufacture of filtering material applicable to the filtration and purification of water, sewage effluents, saccharine juices, alcoholic liquors, and other liquids and fluids. October 9.

1889.

10,991. P. H. Adams, jun., and O. T. X. Adams. See Class X.

11,020. P. H. Adams, jun., and O. T. X. Adams. See Class X.

12,514. J. Y. Johnson.—From La Compagnie Industrielle des Procédés Raoul Pietet, France. A mixture for use in apparatus for producing cold. October 2.

13,212. R. Reichling. Apparatus for evaporating, cooling, or heating liquids, and for charging gases with vapours. October 2.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

14,644. W. P. Thompson.—From F. P. Dewey, United States. Improvements in or appertaining to the separating and collecting of the solid materials from fume, smoke, or the like. Complete Specification. September 17.

14,686. H. Howell and L. Smith. A new or improved automatic carburettor or apparatus for enriching or generating illuminating gas from volatile liquid hydrocarbons. September 18.

14,715. E. Mansfield. Improvements in oil-gas apparatus. September 18.

14,717. G. W. Macalpine. An improvement in coke-oven valves. September 18.

14,881. A. Kitt. Improvements in gas-making apparatus. Complete Specification. September 20.

14,922. A. Kitson. Apparatus for manufacturing heating gas. Complete Specification. September 21.

14,990. J. R. Wigham. Improving the illuminating power of lighthouses and other places. September 23.

15,106. C. McKenzie Dowie and A. L. Briggs. Improvements in apparatus for carburetted illuminating and other gas. September 25.

15,269. J. Dunn and J. K. Thompson. Improvements in an appliance for economising the consumption of fuel and obtaining greater heat. September 28.

15,409. J. Somerville and S. Cutter. Improvements in apparatus for charging and drawing gas retorts. October 1.

15,421. H. G. F. de Beaumont. Improvements in the manufacture of water-gas. October 1.

15,426. M. A. Morse. Improvements relating to the manufacture of gas and to apparatus therefor. Complete Specification. October 1.

15,500. P. G. Lambert. A device for increasing the illuminating power of gas. October 3.

15,797. J. R. Paisley. Improvements in or connected with apparatus for the manufacture of water-gas applicable for gas engines and other purposes. October 8.

15,906. C. Bernard. Improvements in or relating to coke furnaces. October 9.

15,947. J. H. Fergusson. Improvements in and connected with the manufacture of illuminating gas from coal and analogous material. October 10.

15,988. J. Haworth. Improvements in apparatus for manufacturing illuminating and heating gas. October 11.

16,009. J. Lawson. Improvements in oil-gas producing apparatus. October 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,655. W. T. Walker. Desulphurising the lime used in gas purifiers, and recovering the sulphur therefrom. October 9.

15,983. B. Loomis. Process and apparatus for manufacturing fuel gas. October 9.

16,118. C. Brotherhood. Apparatus for automatically controlling the generation of gas from oil or other liquid fuel. September 25.

16,194. J. H. R. Dinsmore. Manufacture of illuminating gas. September 25.

16,927. R. R. Hutchinson. Generating gas from hydrocarbon oils, and apparatus therefor. October 9.

16,958. J. E. Dowson and A. Dowson. Apparatus for use in the treatment of gas. October 2.

17,738. J. A. Yeaton and R. Middleton. Machinery for manufacturing blocks or briquettes of fuel or materials for smelting, &c. October 16.

1889.

1326. J. Greenfield.—From C. A. d'Assumpção and E. S. Dias. Treatment of coal and small coke or breeze in the manufacture of gas and coke. September 25.

13,129. C. B. Harris. Making incandescing elements for gas burners. October 2.

13,763. E. Tatham. An improved gas, usable as an explosive, and, in admixture with other gases, as an illuminating and heating gas. October 16.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

15,175. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brüning, Germany. Improvements in the production of amido-oxy-naphthalin-disulphonic acid and of amido-dioxy-naphthalin-monosulphonic acid. September 26.

15,176. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brüning, Germany. Improvements in the production of amido-naphthol-monosulphonic acids. September 26.

15,296. A. G. Green. The production of new azo-colouring matters. September 28.

15,360. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran. Manufacture of new derivatives of tannin and catechin and of colouring matters obtained therefrom. Complete Specification. September 30.

15,558. F. Rhodes. Improvements in dye-extracting apparatus. Complete Specification. October 3.

15,678. W. R. Lake.—From Messrs. Kern and Sandoz, Switzerland. Improvements in the manufacture of colouring matter. October 5.

15,706. M. Lange. A process for the production of thioxydiphenylamine. October 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,822. O. Imray.—From The Farbwerke vorm. Meister, Lucius, and Brüning, Germany. Production of green and bluish-green colouring matters. October 9.

17,094. C. F. X. Noroy. A new dyeing material, and method of employing the same. October 2.

18,425. S. Pitt.—From L. Casella. Bluish-black colouring matters. October 16.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

14,751. I. Smith. Improvements in the treatment of woollen, worsted, back-worsted, unions, and other woven fabrics. September 19.

15,135. J. E. Richardson. Improvements in the preparation or treatment of esparto grass for use in the manufacture of carpets, matting, twine, and other materials. September 25.

15,333. K. T. Sutherland and G. Esdaile. Improvements in the treatment of fibres and fibrous materials made of China grass, flax, hemp, &c., by which means such can be more easily cleansed or bleached. September 30.

15,916. I. Leviustein. See Class XIX.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,173. J. Holden and J. R. Jepson. Manufacture of felt. September 25.

14,316. J. Grunhut, E. Gonty, and F. B. Gonty. Process for waterproofing materials or fabrics. October 16.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

14,610. R. Nickels. Improvements in the method of and apparatus for dyeing and otherwise treating cotton and other vegetable fibres in sliver, roving, yarn, or other state of preparation. September 17.

14,710. A. S. Bowden.—From A. Vendôme, France. Improvements in machines for printing designs on paper or other material, applicable to decorating earthenware, china, and other similar articles. September 18.

15,094. R. Locfler. A new mordant for dyeing vegetable fibres. September 25.

15,671. L. Schreiner. Improvements in bleaching. October 5.

15,881. J. C. Mewburn.—From La Société Grandsire et fils, France. Improvements in apparatus for dyeing skeins. October 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,955. J. W. Hepworth. Method and apparatus for dyeing woollen cloths, &c. September 25.

18,780. H. Recker. Process and apparatus for dyeing cotton yarn. October 16.

18,987. J. Pollard. Apparatus for washing, bleaching, dyeing, &c. textile fabrics. September 25.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

15,322. C. T. Casebourne. Improvements in or relating to the conversion of brine into salt. September 30.

15,531. W. L. Wise.—From Messrs. Solvay and Co., Belgium. Improvements in and connected with apparatus for producing gaseous hydrochloric acid. October 3.

15,649. F. Bale. Improvements in obtaining ammonia, chlorine, and hydrochloric acid from ammonium chloride, and in the apparatus employed therein. October 5.

15,652. J. Grossmann. The purification of alkali waste. October 5.

15,655. J. Grossmann. Improvements in the manufacture of nitrite of soda. October 5.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,097. J. R. Wyld, M. J. Hammill, and H. Auer. Separating chlorate of potash (and, if desirable the chloride of calcium or magnesium or other similar salt in the mother-liquor) from solutions thereof. October 2.

15,256. A. C. Ponton, B. L. Mosely, and C. Chambers. Crystallisation of silica in a compacted mass. October 16.

15,367. H. W. Wallis. Production of carbonate of soda. September 25.

17,367. T. Parker and A. E. Robinson. Manufacture of chlorine. October 16.

17,447. T. Parker and A. E. Robinson. Manufacture of cyanogen compounds from sulpho-cyanides. October 9.

17,564. Sir L. Bell, Bart. See Class I.

17,569. F. Foster. Apparatus for generating carbonic acid gas. October 16.

1889.

382. M. Williams. Manufacture of barytes. October 16.

8883. C. A. Doremus. Process for removing salts of calcium, magnesium, and other metals from aqueous solutions. September 25.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

14,653. A. J. Clay. Improvements in the manufacture of glazed bricks and tiles. September 17.

14,710. A. S. Bowden.—From A. Vendôme. See Class VI.

14,723. F. Fehse. Improvements in the manufacture of decorative tiles and ornaments. September 18.

15,801. Sir H. Doulton and J. Slater. Improvements in decorating china and the like. October 8.

15,831. F. P. Meyenberg. Improvements in brick and pottery kilns. October 8.

15,959. T. C. Brown-Westhead, Moore, and Co. Improved process of printing in clays, applied to gold, silver, and colour decorations on china and earthenware and pottery generally. October 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8597. J. Stiel. A weather- and acid-proof enamel for building materials, and method of producing same. October 9.

9148. F. E. Grosse. Process for manufacturing iridescent, blown, rolled, or pressed window glass. October 9.

9960. D. Lucas. Printing upon and decorating china, earthenware, or glass. September 25.

13,128. A. G. Neville. Glass melting pots. September 25.

13,880. M. W. Griswold and W. B. Atterbury. Manufacture of sheet or window glass. October 9.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

14,600. J. Cockburn. Improvements in the manufacture of pavement, floor coverings, and the like, of rubber or rubber compounds. September 17.

14,643. W. Torrance, jun. Improvements in or relating to the manufacture of Portland cement. September 17.

14,733. D. Nicoll. Improvements in waterproof slabs and blocks for structural purposes. September 18.

14,778. J. A. Macmickan. Improvements in coping bricks. September 19.

14,963. H. Stanton. Improvements in fire-resisting floors for buildings. September 23.

14,997. A. Bishop. Improvements in the method of burning lime, and in kilns therefor. September 23.

15,115. W. Joy. Improvements in apparatus for separating imperfectly disintegrated chalk and other matters from slurry prepared in wash mills and other apparatus used for mixing and preparing slurry for the manufacture of cement, and improvements in cement kilns, and in the method of loading or charging such kilns, and improvements in mills for grinding cement, clinker, and other like matters, and in apparatus for separating the finer from the coarser particles of ground cement, clinker, and other like matters; and the treatment of cement, and apparatus for use in connexion with the said treatment. September 25.

15,405. J. C. W. Stanley. Improvements in or relating to the burning of bricks or the like. October 1.

15,406. W. J. Oswald, J. R. Ashwell, and J. A. Cooke. Improvements in the manufacture of plaster of Paris, and in the utilisation of waste or cheap materials therefor. October 1.

15,669. J. Ersley. Improvements in the manufacture of artificial asphalt. Complete Specification. October 5.

15,737. W. T. Timewell. Improvements in the manufacture of Portland cement made from hard limestone. October 8.

15,831. F. P. Meyenberg. See Class VIII.

16,015. E. Johnson. Perforated paving. October 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

16,770. C. O. Weber and F. W. Follows. Artificial stones or blocks, applicable for grinding, crushing, granulating, polishing, &c. September 25.

17,257. W. Cussans. Colouring and ornamenting Portland cement for the manufacture of imitation grained or figured marble mosaics, slabs, tiles, &c. September 25.

17,563. W. Lindsay. Fireproof floors. October 9.

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

14,770. E. J. Railton. Improvements in gold screening apparatus. September 19.

14,880. W. R. Lake.—From E. Thomson, United States. Improved methods of and apparatus for welding, shaping, and otherwise working metals. September 20.

15,027. T. Millward. Improvements in furnaces for heating iron or for other purposes. September 24.

15,066. R. Hannan.—From J. J. C. Smith, New Jersey. Casting in aluminium bronze dies to be used for the purpose of stamping metals or other substances for which dies are used. Complete Specification. September 24.

15,144. T. Lambert. The extraction of gold and silver from pulverised ores or other matrix in which these metals are found. September 26.

15,156. B. Moran. Improvements in crucible pots. September 26.

15,226. A. J. Campion. Improvements in the extraction of tin and other oxides from the refuse slags and debris of tin smelting furnaces. September 27.

15,245. E. Grutzner and O. Koehler. Apparatus and process for condensing the metallic vapours produced in zinc furnaces, and furnace applicable in combination with the said condensing apparatus. September 27.

15,301. W. H. Akester, W. T. Glover, and H. Edmunds. Improvements in the treatment or manufacture of metals or metallic alloys. September 28.

15,302. W. H. Akester, W. T. Glover, and H. Edmunds. Improvements in the treatment of metallic castings or forgings for remedying or repairing imperfections thereof.

15,413. T. Twynam. Improvements in the direct reduction of oxides of iron. October 1.

15,428. T. F. Rowland. Improvements in apparatus for welding metals. Complete Specification. October 1.

15,465. D. Rennie. Improvements in furnaces for melting crucible steel and other metals. October 2.

15,552. T. H. Roberts and T. Underhill. Improvements in puddling furnaces and in appliances connected therewith. October 3.

15,563. J. H. Watkins. A resinous fluid or flux, for soldering, brazing, and the like. October 3.

15,729. N. Lébédéff. Improvements in extracting copper and nickel from combinations of these metals with other substances. October 7.

15,792. L. Grabau. An improved apparatus for obtaining metals of the alkalis from molten chloride. October 8.

15,824. G. Archbold. Improvements in the manufacture of iron and steel. Complete Specification. October 8.

15,887. P. P. Craven. A new fluxing or protecting material for use in the welding and brazing of metals. Complete Specification. October 9.

15,970. W. C. Taylor and T. N. Kirkham. Improvements in the treatment of gold-bearing quartz and other minerals for facilitating their reduction to powder. October 10.

16,101. I. Beardmore. Improvements in the distributing of the gases in open-hearth furnaces for steel melting and analogous purposes, and in the means or apparatus employed therefor. October 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,884. L. Q. Brin. Production of alloys of copper with iron or steel. September 25.

14,287. L. Q. Brin. Process for alloying iron and steel with aluminium in the blast furnace. October 2.

14,332. H. W. Wallis. Hardening and tempering steel. October 9.

15,506. L. Q. Brin and A. Brin. Method of plating metals with aluminium, platinum, silver, gold, &c. October 2.

15,507. L. Q. Brin and A. Brin. Alloying metallic aluminium with any other metal. October 2.

16,671. W. C. Roberts-Austen, E. J. Ball, and A. Wingham. Manufacture of iron and steel. September 25.

16,821. A. Arche. Separation of lead from silver, &c. September 25.

16,854. G. M. Edwards and W. J. Griffiths. Machinery for dressing or concentrating tin and other mineral ores. September 25.

17,324. L. H. Cahaigne. Apparatus for the treatment of zinc. October 2.

17,373. R. Middleton. Preparing materials for smelting, &c. October 9.

17,614. B. J. Mills.—From T. A. Edison. Methods and apparatus for effecting the separation of metals from their ores. October 9.

17,614A. B. J. Mills.—From T. A. Edison. Methods and apparatus for effecting the separation of metals from their ores. October 16.

17,614B. B. J. Mills.—From T. A. Edison. Methods and apparatus for effecting the separation of metals from their ores. October 9.

17,738. J. A. Yeadon and R. Middleton. See Class II.

18,020. P. R. Shill. Machinery for crushing or reducing and amalgamating auriferous quartz or ores, &c. October 16.

1889.

560. G. Gatheral. Treatment of copper precipitates. October 2.

10,991. P. H. Adams, jun., and O. T. X. Adams. Apparatus for use in decomposing chemical compounds, metallic salts, and desulphurising ores. October 9.

11,020. P. H. Adams, jun., and O. T. X. Adams. Apparatus for use in decomposing chemical compounds, metallic salts, and desulphurising ores. October 9.

13,013. N. M. de la E. Tenison-Woods. Extracting metals from alkaline solutions, scrap, or waste materials. September 25.

13,138. H. H. Lake.—From G. W. Cummins and J. H. Colman. Treating iron, steel, and other metals to prevent oxidation thereof while in a heated state. September 25.

13,839. H. J. Allison.—From the Great Western Aluminium Smelting and Refining Company, United States of America. Process for obtaining aluminium. October 9.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

14,551. H. A. Henderson. A primary battery solution. September 16.

14,552. H. A. Henderson. Improvements in or relating to primary batteries. September 16.

14,601. G. Macaulay-Cruikshank.—From S. H. Barrett, Massachusetts. An improved connector for the elements of electric batteries. Complete Specification. September 17.

14,677. R. R. Moffatt. Improvements relating to the application and utilisation of electro-magnetism for the separation of metals, and to apparatus therefor. September 17.

14,871. E. Hopkinson and D. Appleton. Improvements connected with or applicable to baths or vessels containing liquids used in electro-plating or dyeing, or the electrolyte of storage batteries and the like. September 20.

14,894. T. Parker. Improved furnace and apparatus for electro-chemical and chemical manufactures. September 21.

14,971. P. J. R. Dujardin. Improvements in secondary batteries. September 23.

15,230. Sir W. Vavasour. Improvements in electric batteries. September 27.

15,235. F. V. Anderson. Improvements in dynamo-electric machinery. September 27.

15,299. J. H. Pratt. Improvements in the electrical reduction and recovery of metals from metallic ores and from compounds and mixtures containing metals. September 28.

15,383. G. E. Heyl. The manufacture of electrodes for accumulators from chromates and wolframates, and particularly from amalgams of chrom, and from amalgams of wolfram with other metals respectively. October 1.

15,446. S. C. C. Currie. Improvements in the method of and apparatus for "forming" or charging plates for electrical accumulators. Complete Specification. October 1.

15,700. W. B. Sayers. Improvements in dynamo machines for electro-plating. October 7.

15,775. C. F. Winkler. Improvements in electro-dynamic and dynamo-electric machines. Complete Specification. October 8.

15,821. S. C. C. Currie. Improvements in the method of electrolytically reducing plates of metallic salts to a metal state to "form" the electrodes of secondary or storage batteries. Complete Specification. October 8.

15,963. P. Schoop. Improvements in the manufacture of electrodes or plates for electrical purposes. October 10.

16,036. W. E. Irish. Improvements in galvanic batteries. Complete Specification. October 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

13,687. R. E. B. Crompton. Electrical furnaces. October 2.

14,322. S. Miller. An improved galvanic cell or battery. October 9.

14,323. S. Miller. Electrolyte or depolarising solution for galvanic batteries. October 9.

15,508. L. Q. Brin and A. Brin. Producing aluminium and its alloys by means of electricity. October 9.

16,479. H. H. Lake.—From H. Walter. Secondary batteries. October 16.

17,537. M. Bailey and J. Warner. Cells for secondary batteries. October 2.

17,694. H. J. Harris and J. Garford. Voltaic batteries. October 9.

18,589. J. L. Huber. Secondary batteries. October 16.

1889.

3222. A. J. Boulton.—From A. K. Reinhold. Treating plates, &c. for facilitating the removal of galvanic plastic deposits therefrom. October 9.

11,471. E. N. Reynier. Electric accumulators. October 2.

11,780. C. E. Buell. Dynamo-electric generators. October 9.

12,145. P. M. Justice.—From E. G. Acheson. Generating electricity or magnetism by the application of heat. October 2.

12,752. H. G. Morris and P. G. Salom. Machines for filling secondary battery plates. September 25.

13,480. W. P. Kookogey. Switching apparatus for charging storage batteries. October 9.

13,636. F. Hughes.—From E. J. McDonald. Manufacture of indigo by the application of electricity. October 9.

13,864. S. C. C. Currie. Apparatus for automatically charging secondary batteries. October 9.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

14,914. W. G. Little. Improvement in soap. September 21.

15,835. J. G. S. Fawns.—From J. S. Burns, United States. Improved manufacture or preparation of lubricating oils or compounds, and a mixture to be used in the said manufacture or preparation. October 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,692. H. Ritter von Dahmen. Manufacture of oleaginous material from hydrocarbons, applicable for saponification, &c. September 25.

17,628. W. Michell and S. Picard. Process and composition for extracting oil from, and cleaning cotton waste. October 16.

19,015. G. T. Bishop. Apparatus employed in the manufacture of soap. October 16.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

14,569. F. Eekstein. Improvements in translucent plastic compositions. September 16.

14,797. R. Barton. Improvements in paints or compositions for covering surfaces. September 19.

14,828. E. G. Stidder. A blacklead varnish for grates, stoves, and other objects usually polished after the application of blacklead. September 20.

14,889. A. French and J. Gordon. Improvements in making white pigments of lead. September 21.

15,255. W. C. Edwards and J. H. W. Smeed. A new or improved ink powder. September 27.

15,805. W. L. Wise.—From J. P. Perkins. A new pigment or paint base and processes of producing the same. October 8.

15,826. A. J. Boulton.—From W. Kiel, United States. Improvements in or relating to the manufacture of vulcanised plastic compounds. October 8.

15,949. H. Thame. Improvements in plastic compositions and the moulding or manufacture thereof into various forms. October 10.

16,039. J. H. Noad. A process and apparatus for the manufacture of carbonate of lead or white pigment. October 11.

COMPLETE SPECIFICATION ACCEPTED.

1889.

13,345. W. P. Thompson.—From P. Leonard and P. Zen. Anticorrosive composition for protecting iron vessels. October 2.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

14,595. A. Hull. An improved method of preparing hides for tanning. Complete Specification. September 17.

14,774. C. Hough. An improved means or mode to be employed in the liming and tanning of skins. September 19.

15,450. B. Nicholson and T. Palmer. The treatment of tanning extracts and other vegetable extracts for decolourising and preserving the same. October 1.

15,777. G. Hand-Smith and P. Warnford-Davis. Improvements in rendering ivory, bone, horn, wood, and similar materials non-absorbent. October 8.

16,081. A. Kraft. Process and composition for producing a new or improved gilding size. October 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,126. P. Jensen.—From D. Pierson, jun. Process of chrome-tanning leather, and the article produced thereby. October 16.

13,542. R. C. Waut.—From G. Mitchell and R. W. Rutherford. Means and process for preparing skins and hides for tanning. October 9.

XV.—AGRICULTURE AND MANURES.

APPLICATIONS.

14,633. N. B. Powder. A compound of animal substances and earths containing phosphate of iron and alumina for fertilising purposes. Complete Specification. September 17.

14,719. A. Manbré, sen. See Class XVII.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATION.

14,940. W. T. Crooke. Improvements in pockets or bags employed in the manufacture of sugar and like substances, together with an improved process for cleansing the same. September 23.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,339. A. Baumgarth. Refining sugar, and apparatus therefor. September 25.

1889.

12,393. W. Fairweather.—From The Babcock and Wilcox Co. Bagasse furnaces. October 2.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

14,584. H. M. King. Purification of beer bottles, wine barrels, vats, and utensils used by brewers, distillers, and wine merchants. September 16.

14,642. L. Frisch. Improvements in or relating to the manufacture of beer, ale, porter, and the like. Complete Specification. September 17.

14,719. A. Manbré, sen. Improvements relating to the manufacture of spirit from grain and cereals, and to the treatment of the by-products derived therefrom for producing cattle-food, charcoal, and manure. September 18.

14,928. A. Manbré, sen. Improvements relating to the manufacture of refined malt and extract from barley malt and from barley malt and amylaceous substances, and the treatment of the spent grains for the production of cattle-food. September 21.

15,064. A. Manbré, sen. Improvements relating to the production and manufacture of methylated spirit, and the treatment of the by-products derived therefrom. September 24.

15,401. A. J. Boulton.—From Otto and Schwerdtfeger, Saxony. Improvements in or relating to the preservation of beer and the like. October 1.

15,568. J. F. Gallogly. A process for maturing and mellowing of new whiskies, brandies, and all other liquors containing alcohol, producing in a few months a similar result to that obtained by many years' storage. October 4.

15,624. W. R. Lake.—From F. A. Reihlen, Germany. Improvements relating to ferments and to the fermentation of liquids. October 4.

15,772. J. Bruce. Improvements in the manufacture of yeast. October 8.

16,079. C. Huelser.—From N. Reif, Germany. An improved cooling apparatus for brewing purposes. October 12.

16,093. W. P. Thompson.—From La Société Générale de Maltose, Belgium. Improvements in or relating to a process for the saccharification and fermentation of amylaceous matter. October 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,972. I. Traube. Separation of mixtures of ethyl alcohol and water from fusel oil and other impurities, and apparatus therefor. October 9.

1889.

13,451. D. R. J. J. G. Morel. Apparatus for mixing water with malt for supply to mash tuns. October 2.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

14,670. A. A. Freeman. Improvements relating to the preservation of shell-fish. Complete Specification. September 17.

15,205. W. Peacock. Improvements in apparatus for effecting the preservation of fruit. September 27.

15,526. B. Graf and F. Piekenbroek. An improved process for producing ozone water, in which the ozone is retained for a considerable period without alteration. Complete Specification. October 3.

B.—Sanitary Chemistry.

14,734. F. P. Candy. Improvements in the deodorisation and purification of sewage and other polluted water. September 18.

15,190. H. Rohrbeck. Improvements in method and apparatus for disinfecting by means of saturated steam of a high temperature. September 26.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1889.

14,23. F. McIntyre. Process and means for the preservation of milk. 9 October.

B.—Sanitary Chemistry.

1888.

14,108. W. Clark and W. A. Clark. Treatment of sewage and apparatus therefor. October 2.

15,810. E. Knowles. Combination of mechanical applications for the purification of sewage. October 9.

1889.

4411. J. B. Paddon. Method and apparatus for destroying town and other refuse material. October 9.

C.—Disinfectants.

1888.

15,925. T. Rowan, L. Hakeman, and The Coal Tar Disinfectants Co. Apparatus for distributing disinfectants. October 2.

15,993. C. T. Kingzett. Preparation and preservation of peroxide of hydrogen. October 16.

15,994. C. T. Kingzett. Preparation of antiseptics, disinfectants, and sanitary reagents. September 25.

17,042. G. R. Tweedie. Compositions for disinfecting, deodorising, or antiseptic purposes. October 9.

1889.

2858. W. H. Daniels. Antiseptic compounds for preserving perishable articles. October 2.

9256. J. Shaw. "Purifying sewer gas, and ventilating sewers, drains, &c.—a deodoriser." September 25.

14,032. J. G. Flower and D. W. Macdonald. Disinfecting, deodorising, and preserving compound. October 16.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

14,793. J. M. Baines. Improvements in the manufacture of paper or cardboard and other similar boxes. September 17.

15,122. J. Luke, jun. Improvements in and relating to the manufacture of paper for mill wrappers, lappings, boxes, and such like, and in machinery connected therewith. September 25.

15,499. H. Brocklehurst. Producing a coloured transparent material made from papier-mâché, &c., called "Glacialite." October 3.

15,916. I. Levinstein. A new or improved material or compound to be used in finishing paper and textile fabrics. October 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,643. I. S. McDougall and J. T. McDougall. Boilers or digesters lined with lead or other acid resisting metal or alloy, especially suited for use in preparing paper making materials or for analogous purposes. October 9.

15,956. J. H. Shorroek. Machine for preparing or finishing wood pulp and other fibres for making paper. September 25.

16,943. J. Mactear. Treatment of esparto grass. October 2.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,443. H. Baum. Production of aromatic ditbio-oxy-carbon acids. October 16.

17,075. J. Y. Johnson.—From F. von Heyden. Production of paraoxybenzoic acid. September 25.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

14,557. A. M. Browne. The manufacture of "dry plates" for photography. September 16.

14,701. J. Malloch. A glass plate or other transparent substance coated with a nonactinic film, and used as a negative for photographic and other purposes. September 18.

15,263. W. Brierley.—From R. Schorr, Germany. Improvements in method of and process for producing coloured impressions, lithographs, or zincographs by aid of photography. September 28.

16,106. J. S. Fairfax.—From F. Crane, United States. Improvements in films for photographic purposes. October 12.

XXII.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

14,614. S. Stocks. Improvements in matches. September 17.

14,678. A. V. Newton.—From A. Nobel, France. Improvements in cartridges, and in guns to be used therewith. September 17.

14,804. H. Stephenson. Improvements in the manufacture of certain fireworks for display purposes. September 19.

15,883. H. J. Haddan.—From L. Azémar, France. A new or improved explosive. October 9.

16,028. P. Molyneux. Improvements in or connected with wax matches. October 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,229. C. J. F. M. Lilliehöök. Percussion fuses for shells. September 25.

14,962. J. B. Readman. Producing phosphorus. September 25.

15,159. J. C. Thompson. Mechanical fuse for exploding shells and indicating number of revolutions performed and distances traversed by projectiles. October 2.

15,934. A. Nobel. Fuses for armour-piercing shells. October 2.

16,213. H. S. Maxim. Manufacture of explosives, and apparatus therefor. October 2.

16,594. T. A. Bayliss. Percussion fuses for quick-firing cartridges, &c. October 9.

16,693. T. Nordenfelt. Torpedoes. October 16.

16,997. H. M. Chapman. Percussion caps or fuses. October 2.

17,212. J. Sayers. Explosive compounds. October 9.

17,719. T. Parker and A. E. Robinson. Manufacture of phosphorus. October 15.

17,772. W. S. Simpson. Explosive shells. October 16.

18,181. T. Nordenfelt. Base fuses for projectiles. October 16.

18,241. G. Trench. Explosives. October 16.

1889.

12,089. P. Giffard. Mining or blasting cartridges, and shells or explosive projectiles. September 25.

12,427. W. E. Liardet. Explosive compounds. October 16.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

15,800. H. Cortland. Improvements in thermostats. Complete Specification. October 8.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 11.—VOL. VIII.]

NOVEMBER 30, 1889.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

COUNCIL FOR YEAR ENDING JULY, 1890.

President: Sir Lowthian Bell, Bart., F.R.S.

Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Benilton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

NOTICES.

Members are hereby advised that the subscription of 25s. for 1890 falls due on January 1st next. Only those members who have paid their subscriptions will be entitled to receive the Journal.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE AND SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

LIST OF MEMBERS ELECTED, 22nd NOVEMBER, 1889.

Anderson, Robt. T. R., 618, Gallowgate Street, Glasgow, technical chemist.

Burton, Wm., 18, Victoria Street, Basford, Stoke-on-Trent, potter's chemist.

Feodossieff, Capt. G., 11, Great Masterskaia, St. Petersburg, Imperial Russian Navy.

Grant, Arthur L., 35, Gould Street, Toronto, Canada, analytical chemist.

Lea, Horatio H., 39, Aldermanbury, E.C., manufacturing chemist.

Macintosh Jas. B., 21st Street and Avenue A., New York, U.S.A., chemist to Consolidated Gas Co.

Peace, Frank K., General Post Office, Sydney, New South Wales, assayer.

Schlichter, H., 2, Linden Cottages, Wimbledon, doctor of natural science.

Vautin, Claude, T. J., Johannesburg, via Cape Town, South Africa, metallurgist.

Wadman, Walter E., 15, Perry Street, New York, U.S.A., manufacturing chemist.

Watts, Sidney E., Tyne Brewery, Newcastle-on-Tyne, brewer's chemist.

White, Henry, 8, Brown Street, Mashboro', Rotherham, manufacturing chemist.

Williams, Rupert Greville, P.O. Box 35, Albany, N.Y., U.S.A., dye manufacturer.

CHANGES OF ADDRESS.

Boam, F., 10 Leicesters; Coombe Arsenic Works, Callington, Cornwall.

Bradburn, J. A., 10 West Genessee Street; The Crouse, Warren Street, Syracuse, N.Y., U.S.A.

Butler, Wm.; Journals to Elmdon, Selly Park, near Birmingham.

Claudet, A. C.; Journals to 9, Dulcham Gardens, Hampstead, N.W.

Ewens, Paul, 10 Maida Vale; Grima, Wimbledon, Surrey.
Galbraith, Wm., 10 Stoke; e/o Wingerworth Iron Co., Chesterfield.

Glover, Jno., 10 Jesmond Dene; 20, Holly Avenue, Newcastle-on-Tyne.

Green, German, 10 Croft Terrace; Bergholt House, Park Road, Jarrold-on-Tyne.

Green, Jno. E.; 52 (not 32), Claypath, Durham.

Greenhough, D. W., 10 Mincing Lane; 5, Rood Lane, London, E.C.

Hamilton, Geo., 10 Kensington Crescent; Gowerton, near Swansea.

Hunter, T. G., 10 Wayne; 540, Drexel Building, 54th Street, Philadelphia, Pa., U.S.A.

Kingdon, J. C., 10 Belgium; e/o Bart, Boulton, and Haywood, Latresne près Bordeaux, France.

Morley, Dr. H. Forster, 10 Gordon Square; 29, Kylemore Road, West Hampstead, N.W.

Parker, Thos., 10 Crawford Street; Newbridge, Wolverhampton.

Powell, A. E., 10 Dryden Street; 478, Stockport Road, Longsight, Manchester.

Reynolds, H. C., 10 Bristol; Thorncliff, Lansdown Road, Cheltenham.

Smith, Thos., 10 Craigmores; Heriot Hill House, Edinburgh.

Thomson, Dr. Andrew, 10 Dundee; 10, Comly Bank, Bridge End, Perth.

Tyrer, Thos.; Journals and communications to 179, Bridge Road, Battersea, S.W.

CHANGE OF ADDRESS REQUIRED.

Wilson, A., 10 Stafford.

Death.

SESSION 1889-90.

Dec. 2nd:—

Mr. Watson Smith. "Some Notes on Variations in the Products of the Destructive Distillation of different Gas Coals, heated separately in the same retort and under similar conditions."

Mr. J. Hauff. "Cresotinic Acid and its Applications."
Mr. G. E. R. Ellis. "A New Hydrocarbon Assay Furnace."

1890.

Jan. 6th:—

Mr. C. T. Kingzett. "Peroxide Hydrogen. Its Preservation and Commercial Uses."

Mr. J. W. Lovibond. "An Analytical Tintometer."

Feb. 3rd.—Messrs. A. H. Allen and W. W. Staveley. "On the Properties and Applications of Metallic Compounds of the Phenols."

Notices will be found in the Journal and other Scientific Papers.

Meeting held Monday, November 4th, 1889.

MR. DAVID HOWARD IN THE CHAIR.

AN ACCOUNT OF A BORAX LAKE IN CALIFORNIA.

BY C. NAPIER HAKE.

Features of the Region.—Before entering upon a detailed description of the dry Salt Lake, the subject of this paper, I propose to put before you briefly some of the more striking geographical and geological features of the remarkable region in which this lake is situated.

Between the Sierra Nevada, on the west, and the Rocky Mountains, on the east, and from the 35° N. Lat. to the Columbia, may be found a succession of interior depressions of a particular character, inasmuch as the rivers and watersheds do not empty themselves into the sea, but are absorbed by the sands of the great desert or lost in the salt lakes. The most remarkable of these depressions, which is known as the Great Basin, is situated from 4,000 to 5,000 feet above the sea-level and occupies an area of 202,500 square miles. Its form is almost a square and its diameter

GENERAL VIEW OF THE BORAX LAKE & WORKS.

from east to west about 500 miles. Surrounded on all sides by lofty mountains, its lakes and rivers have no visible communication with the ocean. Partly arid and scarcely inhabited, the feature of this vast country is that of a wilderness.

The interior of the Great Basin is dotted with mountains of a uniform aspect, each rising abruptly from a base of from 2 to 20 miles in circumference, to a height varying from 2,000 to 5,000 feet above the plain; their slopes are covered with trees and verdure, and their summits are capped with snow during the greater portion of the year. This on melting causes innumerable torrents, which are afterwards lost in the lakes, or sucked up by the sand.

Another grand characteristic of these deserts is the phenomenon caused by the rivers rolling with a crashing noise through the enormous ravines which the Mexicans call *cañons*. These ravines, which are often impenetrable, are hollowed out by the action of the waters to a depth of 300, and even in some places 900 feet, their faces being usually quite perpendicular and so close that you could easily cross from one bank to the other by means of a bridge a few yards in length.

Amongst the rivers irrigating the Great Basin the finest is the Humboldt. This river has two branches which take their sources in a group of mountains situated to the west of the Great Salt Lake. After a course of 55 miles the two branches unite in one bed. For upwards of 300 miles no obstacle whatever impedes its course and no tributaries run into it. As it advances towards the west it gradually loses part of its volume, owing to the absorption and evaporation of its waters, and finally is lost near the Sierra Nevada in a muddy lake or "sink," the borders of which are flat and whitened by saline incrustations.

The other rivers of the Great Basin on the west are the Salmon River, which flows into Lake Pyramid, the Carson, the Walker, and the Owen, which descend with a terrific noise from the Sierra Nevada, and then disappear in lakes to which these rivers give their name.

Such is the general aspect of these deserts. Except in certain valleys where fertility and beauty afford a most striking contrast to their bleak surroundings, the soil is to all intents and purposes sterile. It is chiefly composed of the debris of volcanic rocks. Beds of lava rich in soda felspar cover the country to an extent of many miles; the rain in its season falling on these causes their superficial decomposition and gathers up the soluble salts in its passage. Owing to the general dryness of the atmosphere which prevails, however, for the greater part of the year, evaporation follows solution, and whatever is dissolved tends to rise to the surface, there to crystallise and form what are called efflorescent crusts. These crusts, which at times measure from one foot to 18 inches in thickness, the rain again dissolves away, and if the region contains natural depressions or basins these are transformed into saline lakes. The saline deposits or incrustations so largely distributed over this great plain include common salt, carbonate of soda, sulphate of soda, sulphate of alumina, sulphate of magnesia, borax and borate of lime, sulphate of lime, and carbonate of soda and lime, &c.

Borax Deposits in Northern California.—The first deposits of borax discovered in California are situated in Lake County, about 100 miles north of San Francisco. Some of these deposits were worked successfully between 1864 and 1874, but they now lie idle.

Discovery of Borax in Nevada.—The history of the discovery of borax and borates in Nevada may be briefly summed up as follows:—

In 1864 some borate of lime in the form of cotton balls (ulexite) was found in Columbus Marsh, but no particular notice was taken of this discovery beyond sending specimens to Washington, where they found a place in the cabinet of the State Museum. Between 1869 and 1871 a systematic search was made which resulted in the rediscovery of the deposits in Columbus Marsh and other deposits of ulexite near Salt Wells. These deposits were worked for a short time only. In 1873 the deposits known as Borax Lake and Teel's Marsh were discovered. The former lies in the Mojave Desert, the latter in Nevada. Both deposits are very extensive. A little later a third deposit was discovered near Dagget consisting of borate of lime (colemanite).

Situation of Borax Lake.—The Borax Lake, which specially interests us this evening, is situated in the extreme north-west corner of San Bernardino county, and is 450 miles distant from San Francisco in a south-easterly direction.

Mojave station, on the Atlantic and Pacific Railway, the nearest point of shipment, is connected with the lake by a good waggon road, 72 miles in length.

The lake lies in the valley of the Slate Range and Argus Mountains at an elevation of 1,700 feet above the sea. It is oval in shape and its greatest length and breadth is 12 miles by 8 miles. The greater part of it is covered with a hard saline incrustation varying in thickness from a few inches to several feet. The surface is covered with white efflorescent matter largely mixed with sand. Under the hard crust the lake consists of one vast bed of black mud containing a large proportion of iron sulphide saturated with saline matter and strongly impregnated with sulphuretted hydrogen gas. The thickness of this mud-bed has not been determined.

In the lake is contained common salt, carbonate of soda, hydrated and anhydrous bicarbonate of soda, baborate of soda, sulphate of soda, hydrated and anhydrous sulphate of magnesia, salts of ammonia, and traces of bromine and potash. Although I made a diligent search during the four weeks I remained on the lake I was unable to detect a trace of iodine. A new and highly interesting mineral has been discovered in the mud of this lake in small hexagonal crystals, to which the name of "Hanksite" has been given after Professor Hanks, of San Francisco, whose name is so honourably connected with the mineral development of California. Its composition is expressed in the formula—

The lake may be for all practical purposes divided into three sections, each section representing well defined deposits of—

- (1) Biborate of soda.
- (2) Bicarbonate of soda, and
- (3) Common salt.

The borax occupies the northern portion of the lake. A very pure deposit of bicarbonate of soda lies on the N.E. shore. The remaining surface deposits consist chiefly of common salt, which becomes purer towards the southern extremity of the lake.

The common salt and bicarbonate of soda deposits have at present no commercial value. The latter is, however, of considerable interest as an example of the ammonia-soda process being carried on by nature. All the ingredients necessary for this process are contained in the waters underlying the deposit, viz., ammonia, carbonic acid, and common salt. The deposit is from 6 in. to 18 in. thick, and in many places almost chemically pure.

Crystal Beds.—Near the centre of the borax section, which is the lowest level of the lake, there exists a patch covering an area of about 300 acres, which is nearly always covered with water to a depth of from one inch to a foot. This patch is called "the crystal bed," from the fact that the mud underlying the water is full of large crystals. These crystals are not deposited regularly, but form nests several feet in thickness, and penetrating 3 or 4 ft. downwards.

The spaces intervening between these nests are filled up with mud, and are comparatively free from crystalline deposit. By damming off the water I was enabled to make an examination of some of these nests. The crystals thrown out consisted of carbonate of soda and common salt, with a large proportion of borax, some of the crystals of which measured as much as 7 in. During one exceptionally dry season, when the water was low, about 700 tons of borax were refined from this source.

The underlying water, at a depth of 15 ft., contains—

- Carbonate of soda,
- Chloride of sodium,
- Sulphate of soda,
- Borax, and
- Salts of ammonia.

The ground around this crystal bed consists of a dry hard crust about 1 ft. thick. This crust contains carbonate and sulphate of soda and about 1 per cent. of borax. On this hard crust there is, again, another deposit of efflorescent matter, containing about—

	Per Cent.
Sand	50
Sulphate of soda	16
Common salt	12
Carbonate of soda	10
Borax	12

This surface deposit represents the chief source of raw material for the manufacture of refined borax.

The deposit is worked in the following manner:—

Method of Working Deposit.—When the crude efflorescent surface has accumulated to a depth of about 1 in. in thickness it is loosened by means of a shovel and swept into wind-rows, space being left between each wind-row to allow of the passage of a cart.

The surface thus cleared of its salts begins to renew its coating. The moisture as it creeps upwards is evaporated by the heat of the sun, leaving the solid matter, which is held in solution on the surface. This action is allowed to go on for three or four years before the surface is again disturbed. In order to get some idea as to the proportionate growth of the different salts contained in this efflorescent matter, I took samples representing 6 months' growth, 2 years' growth, 3 years' growth, and 4 years' growth. From all the sections from which these samples were taken, the surface has been removed three or four times during the last 12 years, and in most places marks of the old wind-rows were visible.

ANALYSES OF CRUDE BORAX MATERIAL FROM DRY LAKE.

—	Six Months' Growth.	Two Years' Growth.	Three Years' Growth.	Four Years' Growth.
Sand	58.0	55.4	52.4	53.3
Carbonate of soda	5.2	5.0	8.1	8.0
Sulphate of soda	11.7	6.7	16.6	16.0
Chloride of soda	10.9	20.0	11.1	11.8
Borax	14.2	12.9	11.8	10.9
	100.0	100.0	100.0	100.0

The analyses show that the first six months' growth is richest in borax and that the proportion of carbonate of soda to borax appears to increase regularly. The presence of sand in such large quantities is due to the high westerly winds which blow periodically, and drive it from the mountain slopes across the lake. This sand no doubt facilitates the formation of the surface deposit by keeping the ground in a porous condition.

That only this section of the lake produces borax to any extent is due, no doubt, to its low level. The hard crust above mentioned dips in the water which rises by capillary attraction. This contact appears to be a favourable if not a necessary condition, for during very dry seasons, when the level of the water is low, surface reevaporation goes on very slowly, or even ceases entirely.

Process of Manufacture.—The factory, which is situated on the north-west corner of the lake, consists of a dissolving house raised about 20 ft. above the level of the ground, concentration house, a refining house, and boiler house. The process by which the borax is extracted from the crude material is very simple and comprises two operations, viz., dissolving and allowing the solution to crystallise.

The crude material is transported by means of carts from the lake to the works, and is passed through a mill previous to its being thrown into the dissolving pan, in which is contained a boiling saline solution, preferably mother-liquor, from the second crystallisation. The solution is kept boiling by high pressure open steam as the crude

material is being shovelled into it, during which operation free ammonia is copiously given off. The salts dissolve entirely, leaving the insoluble residue, chiefly sand, at the bottom of the pan. The hot solution, after standing for some time in order to clarify, is run off into crystallising pans and allowed to cool for from five to nine days according to the season of the year.

The product of this first crystallisation is a mixture of octohedral and prismatic borax, slightly impure and somewhat coloured by organic matter. This product is either sold as "concentrations" or redissolved in boiling mother-liquor and the resulting solution allowed to cool to 120° F. From this solution refined borax of excellent quality is obtained. The works are capable of turning out over 100 tons per month, about 50 men and 65 animals being employed. The factory is exceedingly well arranged, and substantially built, and under careful and intelligent management.

During the time of my visit at the lake the fuel used on the works was the sage brush, the only wood growth in this desert. The difficulties of collecting this material were enormous. Carts were sent out scouring the country for 10 miles round in search of fuel, and remained away often for a week at a time. This difficulty has been partially met by substituting crude petroleum, which has to be carted 72 miles across the desert. The results, however, I am told, show a saving of nearly 40 per cent. as against the sage brush, besides other advantages, such as greater regularity of working.

Water Supply.—The question of water supply is an extremely interesting one. The water is obtained from two sources. The one which is used for drinking purposes and for feeding the boilers is brought in iron pipes from a cañon lying in the Argus range, 7½ miles distant from the work, at an elevation of nearly 300 ft. This cañon, which forms an oasis in the desert, contains several springs, and where cultivated yields an abundance of fruit and vegetables.

The other supply is derived from artesian wells which are sunk to a depth of 55 ft. on the shores of the lake. The water rises from 3 to 10 ft. above the surface, and the flow is constant and regular.

This water is strongly alkaline, containing about 1 per cent. of carbonate of soda, strong traces of borax, and salts of ammonia equal to about 18 grains per gallon.

Labour.—The question of labour presents no difficulties; all common operations are carried on by Chinamen, and this class of labour can be procured in California at a comparatively moderate rate.

Transport.—The refined borax is packed in casks and transported to Mojave in the so-called "Desert Schooner," a strongly built wagon drawn by 20 mules. The average load is 10 tons, and the trip to Mojave and back takes eight days. The road through the light sandy soil of the desert rises gradually 1,000 feet during the first 25 miles.

This road is controlled by the owners of the lake, who possess the right to the water, which is supplied to the four roadside stations through iron pipes from a range of mountains 10 miles distant. These stations afford sleeping accommodation for the teamsters and stabling for the animals.

During my visit to California I took every opportunity of making myself acquainted with the extent and value of the borax deposits in the Pacific States, and I gathered that, though widely distributed, there are only three deposits of any great importance which are actually being worked at the present time. These deposits yield from 1,500 to 2,000 tons of borax annually, nearly the whole of which is consumed in the United States.

The lake which I have described has been regularly worked for the last 15 years under the direction of Mr. J. Searle, the chief owner, who is known all over California as the keenest bear hunter in the State; but he is not less known for his hospitality, high integrity, and intelligence. During this period it has supplied about one-third of the total amount derived from similar sources and with considerable profit to the owners. The supply of borax on this lake appears to be practically inexhaustible, and it only requires improved means of transport for its full development.

In conclusion, it may be of interest to briefly allude to Death Valley, which lies 100 ft. below the level of the sea. Borax and borate of lime deposits have been discovered and worked in this valley, which is probably the most desolate and least explored of any portion of the United States. The climate, owing to the intense heat and dryness of the atmosphere, is almost unbearable. It is absolutely devoid of either animal or vegetable life. During several months in the year work has to be suspended, one reason being that the solution would not cool down to a temperature at which crystallisation takes place.

The communication which I have made to you this evening will, I trust, prove of interest to the Society, if only as an instance of what can be accomplished in manufacturing chemistry under stupendous difficulties, when the enterprise is directed by intelligent perseverance.

DISCUSSION.

The CHAIRMAN said that the hearty thanks of the meeting were due to Mr. Hake for his able paper on a subject of very wide interest and practical importance. When one remembered that, at a comparatively recent date, borax was selling at 90*l.* a ton, and was a costly material used chiefly for producing the most valuable glazes on pottery, whereas now it was not only extremely cheap, but was found to be available for a vast variety of purposes—even running a good second to some of the most widely-advertised soaps—it was evident that the subject before them had an important practical bearing. The matter also possessed considerable interest in a geological aspect, as an example of the wide distribution of what was once considered a rare element. In the early part of the present century the only sources of borax were the tincal lakes in the North of India and Thibet, where it was obtained in a crystalline state from beds of semi-gelatinous mud. Then followed that triumph of technical engineering, the working of the *lagoons* of Tuscany, where the *solfioni* containing a small quantity of boracic acid were condensed by blowing through water, and the solution thus obtained evaporated down by the same volcanic steam. Italy thus became practically the sole source of the world's supply of borax, its product running the tincal deposits completely out of the market. Next came that singular deposit obtained from Peru, which in appearance closely resembled a very white potato; and lastly came this wonderful American deposit described by Mr. Hake, and Rhodrate—the borate of lime of Turkey. Boron, therefore, instead of being an element of rare occurrence, as was once supposed, was found to be widely spread over different parts of the world. And its applications were likely to be equally wide. It was already known to be the finest of all glazes, a most useful detergent, and one of the most valuable of disinfectants; and its uses were not yet exhausted, seeing that this once chemical luxury was now cheaper than carbonate of soda was a few years ago. He was glad to see that Mr. Robottom was present. He could speak on this subject with more authority than anyone else in Europe or America; and the meeting would, he was sure, be glad to have the benefit of hearing his views.

Mr. ARTHUR ROBOTOM then gave the meeting a vivid and interesting account of his pioneer work in the exploitation of Californian borax; of his journey on foot at the rate of 12 to 14 miles a day, and, disguised as a "busted" miner, across the 240 miles of sterile country lying between Los Angeles and the Mono Lake; his stay at "Jim Bridger's shanty"; his meeting with the pioneers John and Dennis Searle, and the shipment of the first cargo of natural borax to England; his high hopes of future profit from the trade; and his subsequent disappointment and trials on finding himself saddled with an immense quantity of borax, the selling price of which had suddenly declined from 90*l.* to 26*l.* per ton (a figure very little above the bare cost of transport), and which could not be readily disposed of even at that price, owing to the general ignorance of its many good qualities. Mr. Robottom concluded by expressing his conviction that the efforts which he had then made had given such a stimulus to the use of borax as could not fail to result in mutual benefit to traders and consumers. He could not agree, however, with Mr. Hake's statement that there

were only three deposits of natural borax in the region under notice. The supply was inexhaustible, and there were several sources not mentioned by the author.

Mr. Moss desired to inquire of the author of the paper—in view of his statement, confirmed by Mr. Robottom, that the supply of Californian natural borax was inexhaustible—whether he had been able to trace the borax to its origin, and could say in what form the boron was presented to the bodies with which it combined to produce borax. He would also like to know whether Mr. Hake had made any examination of the mud-bed in which the borax crystals were found with the purpose of ascertaining whether it contained any low forms of organisation, which might be the cause or the result of decomposition. The fact that ammonia had been found in the stratum under the crystal-bed suggested that organic matter in some form or other was not far away.

Mr. HAKE, in reply, said that he had listened with great pleasure to Mr. Robottom's remarks, and was glad to find that they generally confirmed his own observations. With regard to the only point of difference between them, he ought to have said that the three deposits which he had described were not the only but the chief sources of supply. There were many smaller deposits in the vicinity, but he had not mentioned them because they were not worked continuously or regularly, and therefore had but little influence on the supply. He had not been able to form any theory as to the source of the Californian borax; it was a question which had puzzled people far better able to judge than himself. He believed that the origin of the boracic acid obtained from the Tuscan lakes had not yet been satisfactorily accounted for, and there was great similarity between the deposits of Italy and those of California—especially those of South California. The whole of the six weeks he had spent in the region was taken up by the practical examination of the great lake, 12 miles by 8 miles, which he had described. He had found that there was one vast bed of mud of apparently uniform character. The presence of ammonia and carbonic acid of course indicated the existence of organic matter; but where it came from no one, he believed, had been able to determine. Very little was yet known of the geology of the region, and perhaps an examination in that direction might throw some light on the subject.

The CHAIRMAN said that he would venture, contrary to Newton's law, to make an hypothesis on the subject. He could not help connecting these natural deposits with that singular mineral known as Colmanite. That was a borate of lime in appearance curiously like borax. He could not say how it was formed, but seeing that there was borate of lime present, and that the natural ammonia-soda process mentioned by Mr. Hake supplied bicarbonate of soda, he could not see any difficulty in Nature doing what art can do—*i.e.*, make borax. Where the Colmanite came from, however, he could not venture to say.

Mr. A. H. ALLEN said that it had been suggested that the boracic acid of the Tuscan lakes owed its origin to the pre-existence of nitride of boron—which would also account for the presence of ammonia. Nitride of boron was decomposed under the influence of water at high temperatures, with formation of ammonia and boracic acid, and in presence of carbonate of soda the latter would easily react to form borax. On this hypothesis they were not bound to associate organic matter with the production of ammonia in the case under notice. He would like to ask the author by what method he had found it most convenient to estimate the borax in presence of sodium carbonate and other sodium salts.

Mr. HAKE replied that his examination having been made some three years ago he was not quite clear upon that point, but if he remembered rightly, he had employed the titration method, using a special indicator. Most of the analyses were made in a laboratory in San Francisco from samples taken at the lake.

THE CONDITIONS OF THE REACTION BETWEEN COPPER AND NITRIC ACID.

BY V. H. VELEY, M.A.

IN the course of some experiments, it was observed that when a sphere of pure electrolytic copper was revolved in dilute nitric acid (of 27.5 per cent. concentration, and heated to 27° C.) no gas bubbles were evolved from the surface of the copper for a few minutes. But if the same sphere were introduced into the same acid containing in small quantities the products of the reaction between the metal and the acid, the evolution of gas commenced immediately. Further, other conditions remaining the same, the amount of copper dissolved per unit surface in a given interval of time was less in the former than in the latter case. In another paper, tables of figures have been given in illustration of these results. In these earlier experiments, however, no especial precautions were taken to purify the nitric acid used from a small quantity of nitrous acid with which it was contaminated. This impurity was subsequently removed by passing a rapid stream of air into nitric acid of sp. gr. 1.41, sheltered from direct sunlight, and heated to a temperature not exceeding 35° C. until a small test portion of the acid gave no immediate blue colouration to a solution of potassium iodide and starch, nor any appreciable tint to a solution of metaphenylenediamine hydrochloride. The acid was then diluted with water to the required concentration; thus prepared, it contained a proportion of nitrous acid less than one part in three but more than one part in five millions of nitric acid. On repetition of the experiments described above, the same results were obtained, and it was shown that when the metal has commenced to dissolve, then the acid contained nitrous acid. But if some substance, such as urea, be added to destroy the small proportion of nitrous acid not removed by the process of purification, and which should also react with any nitrous acid produced in the immediate vicinity of the metal, then copper is not dissolved by dilute nitric acid of 28 per cent. concentration, heated to 27° C., provided that the metal is rapidly rotated, and the acid kept in agitation by blowing in a rapid stream of an inert gas as carbonic anhydride. Substances other than urea are even more effectual in preventing the chemical change. But if these conditions of movement were not fulfilled, then, owing to some local action, the solution of the copper commenced, and when once started could not subsequently be prevented. Thus it would appear that *pure copper does not dissolve in pure nitric acid*, but that the presence of nitrous acid is the necessary condition.

In this respect copper is analogous to silver, which, according to the experiments of Russell (J. Chem. Soc. 1874, 3), dissolves only in nitric acid containing nitrous acid. If the conditions are such that these metals dissolve, then they yield primarily their own solvent nitrous acid. In the case of copper, the chemical changes which take place are probably as follows:—1st. The copper dissolves in nitrous acid to form copper nitrite, which is decomposed by the nitric acid to produce copper nitrate, liberating again nitrous acid. 2nd. The nitrous acid is subsequently decomposed to form nitric oxide, which, in its turn, reduces a further quantity of nitric to nitrous acid. Then the chemical change becomes more rapid until a limit is reached, when the production of nitrous acid on the one hand, and its decomposition on the other, counterbalance one another. The production of nitrous oxide and nitrogen gases is due to subsequent changes effected by the highly-reducible substance cupric nitrate, as pointed out by Armstrong and Acworth (J. Chem. Soc. 1877, 54).

In the course of further investigation, it has been shown that mercury does not dissolve in nitric acid even of 35.5 per cent. concentration and without the addition of substances reacting with nitrous acid, provided that both the metal and acid are kept in motion. In illustration of the experiments described above, G. J. Burch and the author have found that the E.M.F. of copper, platinum, dilute nitric acid is at first about .55 of a volt, but that this increases with the greatest regularity until it reaches a

maximum of about .75 of a volt; but if a trace of nitrous acid is introduced into the pure nitric acid, the maximum is reached *at once*. It is proposed to continue these investigations, reserving their details for a future memoir.

DISCUSSION.

THE CHAIRMAN said he had no doubt that many members had, like himself, been greatly puzzled by this curious perversity of metals in dissolving in nitric acid. Mr. Veley's valuable contribution was an additional proof that many of those beautifully simple formulae which were taught to beginners were, to say the least of them, defective expressions of truth which might be good for the young but were not very good for the old.

MR. C. F. CROSS said that about two years ago he had dealt with a similar reaction. In the article "Cellulose" for Watts' Dictionary (ed. 1888) it was recorded that the action of dilute nitric acid upon lignified tissues (which is to resolve them into cellulose (insoluble) and nitroso-derivatives of the non-cellulose (soluble)), is, in presence of urea, suspended, or rather converted into a simple hydrolysis similar to that of dilute hydrochloric acid or sulphuric acid. By using varying proportions of urea in a 5 per cent. solution of nitric acid, and digesting this mixture at 60°—80° with any fibres of the lignified class, he had obtained results giving every gradation between the two extremes. Of course the case in point was a special example of what was now regarded as generally true, that without the *tertium quid* no reaction took place.* He might also mention another case bearing on the general question, but in which nitric acid became the determining reagent. It was that of combustion of nitrogenous bodies with chromic acid in presence of sulphuric acid. While most bodies containing carbon, hydrogen and oxygen only, burnt without difficulty and yielded the whole of their carbon in the gaseous form, in the case of nitrogen compounds there were complications and incomplete combustion. It was found, however, that in many cases, notably that of urea, the presence of nitric acid determined the evolution of the whole of the nitrogen as such. Now, it was known that urea had the power of assuming the isomeric form of cyanic acid; and he had found in fact that urea in presence of this oxidising mixture was not burnt, but took the form of cyanic acid, thus accounting for incomplete combustion also of bodies forming urea as a product of severe oxidation. It was evident that the nitric acid determined complete combustion by upsetting the equilibrium of cyanic acid.†

NOTE ON APPLIED TECHNICAL INSTRUCTION IN GERMANY.

BY THOS. CHRISTY, F.L.S.

IT may be useful to place before the London Section of the Society of Chemical Industry some facts which came under my notice during a visit, in September last, in Brunswick. The Government Druggist College was founded in 1880, with the approval of the Druggists' Society of Brunswick. It is the only establishment on the Continent with which I am acquainted which teaches the whole *minutiae* of the druggist's trade. The object being to prepare druggists with a scientific knowledge of their business, the whole organisation is arranged to treat of practical details—an organisation, which while teaching everything worth knowing in connexion with this particular business, omits matters of a secondary and unimportant character.

The students who seek the diploma of the academy vary in age from 16 to 25, and it is generally found that they

* See Chem. News, vol. lx., p. 13.

† Compare J. Chem. Soc., vol. xxxv., p. 12, H. J. H. Fenton. On the Combustion of Urea by Hypochlorites.

have had experience in drug stores or warehouses previously to studying at the academy, their object being, by further study, to obtain a thoroughly theoretical knowledge of the trade. The course of education is distributed over one year, the holidays in which amount to 60 days. Students have to learn the names of all drugs, gums, woods, herbs, spices, &c., and also the way to treat them with ordinary apparatus in practical use, not only relying upon first-class and the latest improved machinery. Further, students are made acquainted with different methods of arriving at a successful result. In the laboratory the work is based on the natural wants of commerce, and in order to help the understanding of those students who may not fully comprehend the lectures, a number of questions are asked after each lecture by which repetition of specific points is ensured and a clearer knowledge of the lectures is gained.

An enumeration of the facilities for acquiring knowledge placed at the disposal of students will convey a very clear idea of the practical nature of the academy.

Amongst means of teaching in the laboratory—which accommodates 34 students—are a collection of 240 scientific instruments, an herbarium, illustrations and diagrams of plants, fruits, &c., photographs of chemical and technical factories, plants and drugs, a sample collection of drugs, essences, perfumes, and chemical preparations, a technological collection of industrial products, and a library of selected works and newspapers.

The subjects of education include inorganic chemistry, in which six hours' instruction is given weekly; organic chemistry, five hours; theoretical chemistry, two hours; technical chemistry, three hours weekly, and analytical chemistry with lectures on working in the laboratory. Two hours per week are devoted to acquiring a theoretical knowledge of drugs, two hours to a practical knowledge of the same, two hours weekly (in winter) to the study of chemicals, and two hours weekly (in summer) to colours, paints, &c., whilst botany has two hours weekly allotted to it in the summer, when it is taught in the agreeable form of country excursions. The programme is completed by taking two hours' weekly instruction (in winter) in chosen subjects in physics, three hours weekly are given to book-keeping by single and double entry, two hours to commercial arithmetic, two hours to correspondence, and 12 hours weekly are spent in the laboratory.

For Germans this course of education lasts one year, and for non-German-speaking students 18 months, Germans being admitted in April and October on production of school certificates, a regulation dispensed with in the case of foreigners.

The school fees amount to 20*l.* a year, payable in two parts; a moiety on entrance, and the other half at the beginning of the second term. The admission fees amount to 6*s.*, the fee for the laboratory servant is 4*s.* per term, for gas in the laboratory 4*s.* 6*d.* per term, for reading in the library and the use of papers 3*s.* per term. All students on entry bind themselves for a whole course.

As a further instance of the practical management of the institution, visits are made to factories where the technical chemistry lectures may be elucidated by practical illustrations on a commercial scale. Soap, candle, alkaloid, and oil works, also to sugar factories, tar and spirit distilleries, the Neuhausen paper mills, the Schöningen chemical works, soda manufacturing, sulphuric acid, hydrochloric acid, chloride of lime, and manure works were visited.

The progress obtained at different stages of the tuition is registered by means of examinations in which each student has to take part. At the close of each month examinations are held, in writing, on all the subjects taught. At the end of each term a theoretical as well as practical examination takes place, the marks for which are added to those obtained at the monthly examinations. From these marks is made up the average stated on the certificates awarded at the end of each term, and from the whole documents for the period of studentship may be ascertained the position of a student on leaving. When specially requested extra examinations are held for diligent but slow scholars.

In the laboratory the work consists of qualitative and quantitative analysis, making chemical preparations, and examining drugs described in the two German Pharmacopœia. The "home" work of a student is judged, firstly, by his written record of the lectures; and, secondly, by the way in which he prepares and describes an herbarium consisting of at least 100 specimens of plants. This latter item is based on a thorough method which includes the collecting, drying, and mounting of specimens on separate sheets, which must bear also a full botanical and medicinal description. A collection of medicinal drugs is made and placed in boxes, the drugs being fully described. Sections are also cut and sketched from microscopical observations, thus enabling a student when in practical business life to detect the true character of any particular article. The drugs are also treated for the extraction of alkaloids or salts, these being shown in bottles. The full history of the drugs is recorded, with their appearances—bark, fruit, foliage, &c.

Although I had seen the programme of this institution, I had not gathered that full idea of its scope and value which has been impressed upon me by becoming personally cognisant with the details as they exist.

What I have endeavoured to make clear is that the students who earnestly avail themselves of the facilities offered by such a course of instruction may, after a year or 18 months' instruction, claim to have good general knowledge. The student, in addition to the attraction offered by the prizes awarded for proficiency, is also encouraged in a more practical way by the knowledge that he can command a lucrative situation if he obtains a good certificate on leaving. There is a great demand from all parts for the holders of such certificates, and when in Brunswick, just after the examinations, I was introduced to some of the students, one of whom was going to Riga, another to Odessa, and the first prize man had taken a situation in Brunswick. Many of them could converse in English and French, and some hoped to obtain appointments abroad and in the English colonies.

The books and examination papers, and collection of specimens of various products made by the student who obtained the first prize, were on the table for inspection.

DISCUSSION.

The CHAIRMAN said that he had been deeply interested by Mr. Christy's account of pharmaceutical training as carried out in Germany. He thought, however, that English pharmacists could boast that they had been before the rest of the world in applying chemistry to their instruction. He could hardly say how the general curriculum would compare with the German; but he heartily wished that such practical work as Mr. Christy had described were the rule rather than that tendency to too much theory which was characteristic of English ideas of technical instruction—at any rate as exhibited in the recent Government Bill on the subject. When the discussion was over he would invite the members' attention to the valuable and beautiful collection of specimens of drugs, &c. provided by the author.

MR. WATSON SMITH, referring to the author's remarks on the opportunities afforded to students by German manufacturers, said that during the seven or eight years in which he had been engaged in teaching applied chemistry in the north of England he had never experienced any difficulty in obtaining permission for his students to inspect chemical works. In fact he had found that manufacturers were not only willing to throw open their works to the inspection of students, but they frequently added to their kindness by putting the party under the personal guidance of one of the directors or managers of the works; and he had found it easy to satisfy manufacturers that none but *bona fide* students were present, by offering his class roll-call, that it might be called over before the inspection commenced. It would, of course, be foolish and unreasonable to expect manufacturers to show any secret or even special processes, but all that students required was to witness the carrying out of the general principles of scientific and industrial chemistry on a manufacturing scale, and that end could be easily attained under ordinary circumstances without prejudice to the interests of the manufacturer.

Dr. C. R. ALDER WRIGHT desired to add to what the Editor had just said, his own testimony as to the liberality of British manufacturers in permitting visitors not engaged in their own particular trade to inspect their works. Neither as a student some 20 years ago, nor subsequently as a member of the British Association and kindred societies, had he found any difficulty in gaining admission to, and much information concerning, works of various descriptions in different parts of the country. There was one sentence in the Chairman's remarks to which he would like to draw further attention. That was regarding the tendency of technical education as at present carried out in this country, towards the theoretical rather than the practical side of the subject.

The CHAIRMAN said he had spoken of the Government Bill—or of technical education as it was to be conducted under that Bill.

Dr. WRIGHT, continuing, said that he hoped he was in accord with the Chairman in saying that one great fault in the present system of teaching applied chemistry was the fact that the teachers themselves, as a rule, did not possess that practical acquaintance with the subject which was necessary in order to fit them to explain it thoroughly. There was a great difference between the chemistry of a scientific laboratory and that of an actual work, and unless a man had been through a course of training in chemical engineering, only to be obtained in the factory itself, he could hardly appreciate the difference. Unless a teacher had been through such a course he could not hope to make it clear to students what chemical technology really was. He felt strongly, therefore, that the technical education of the future would be much more profitably directed from the practical than from the purely theoretical side.

Mr. PETER McEWAN wished to point out with regard to this paper that he understood Mr. Christy to speak of the *druggists* of Germany, who were different from the *pharmacists* of that country. In Germany, druggists held a position similar to that which herbalists held in England, and so far as these two classes were concerned he admitted that the German education of druggists was far ahead of that of British herbalists. But as a matter of fact the whole course of education described by Mr. Christy had been carried out in this country for the last 40 years, so far as pharmacists were concerned. The beautiful and interesting specimens exhibited by Mr. Christy on the present occasion as the work of a German student served to recall to his mind similar collections made 35 or 40 years ago by noted English pharmacists now living. With regard to the practice of visiting chemical works, from the pharmacist's point of view he would like to say that it was not quite necessary, the modern tendency of pharmacopœias being to omit processes. All that the pharmacist had to do in practice was to accurately carry out physicians' prescriptions, to test his chemicals rather than to make them. On that ground there was little use in teaching him the practical methods of manufacturing such chemicals as were generally made only on one large scale, because he would always be able to buy them much purer and cheaper than he could make them himself.

Mr. J. Moss believed that this was the first paper presented to the Society specially referring to druggists as a class. They were an important and influential body, many of them being large manufacturers, and probably the only reason that they did not receive wider recognition from the Society he was addressing, was the fact that they had a powerful Society of their own which was able to attract and absorb all matters pharmaceutical. In bringing forward this subject, Mr. Christy had, he thought, done good service to a cause which was receiving much attention just now—that of technical education. He would like to point out that in Mr. Christy's account of the institution he had described there was nothing to indicate that it was a corporate body. It was rather to be regarded as a private school; and in that respect it had a great advantage over most corporate bodies existing for similar purposes, inasmuch as the men at the head of it were able to make their own arrangements from time to time, and decide what should be the course of study and what the

rules to which every student coming to them should be subject. Another great advantage was the permission to see works. He could hardly imagine the kind of factory which would be useful to a druggist being thrown open to inspection by a school or by individual students. Whatever might be the practice in chemical works in the North of England, he did not think it would be applicable to the works of manufacturing pharmacists in London. The routine described by Mr. Christy included book-keeping and arithmetic. In England, a youth was supposed to be educated in commercial and literary matters before beginning the technical studies of a chemist and druggist. He could confirm much that Mr. McEwan had said with regard to the Pharmaceutical Society of London. When that Society was first installed its laboratory was the finest in the country for practical instruction. It now possessed a museum of *materia medica* which was second to none, and the specimens were open to every student under the guidance of the curator, who was always willing to give his services. It had, too, a library of he could not say how many thousand volumes—a library unequalled in Europe from the pharmaceutical point of view. So that with regard to the materials needed for teaching, England was as well supplied as any country need be; but no doubt in some respects Germany had the advantage, and it was well for us to know that and learn from our rival. For example, the obligation laid on students to produce their note-books from time to time and make up specimens under the guidance of their teacher were points which English teachers of pharmacy might copy with great advantage. He hoped that this paper would be the means of impressing them with the necessity of doing so, and that the students who worked under such conditions would turn out even better than formerly.

Mr. T. TYRER said that he felt a deep personal interest in this matter, and would like again to assert his conviction that English professors were not behind their foreign rivals. He did not know whether the custom was first introduced by Hofmann, but he gratefully remembered that that great teacher made it his regular practice, firstly, to become personally acquainted with every student under him, secondly to call upon every such student to produce his note-book periodically; almost daily indeed. If the student failed to do so, he speedily got the "cold shoulder," which in Hofmann's case was a thing to be remembered. Whether Hofmann set the example or not, he believed it was a fact that the system was followed now by every teacher worthy of the name.

DR. F. HURTER IN THE CHAIR.

THE CONDENSATION OF HYDROCHLORIC ACID GAS.

BY F. HURTER, F.I.D.

In an old syllabus of the City Guilds I found, many years ago, a statement that students should be acquainted with the theory and practice of the condensation of hydrochloric acid. I felt at the time that I was tolerably well acquainted with the practice of the condensation of hydrochloric acid, but I had to confess that of the theory I was ignorant; and I often wondered what the authorities of those days meant by the term.

Clearly, a complete theory of the condensation of hydrochloric acid must enable us to answer questions such as this: What is the highest strength of liquid hydrochloric acid which can be obtained from a gas of known composition, and what conditions must be satisfied to obtain acid of that strength?

Such a theory of the condensation of hydrochloric acid does not exist, and many problems which have presented themselves to me in my practice have urged me to collect the materials for such a theory, and to devise one which should allow us, with great approximation to truth, to answer such questions as the one proposed.

A really complete theory of the condensation of hydrochloric acid would, however, require a great deal more experimental data than are at present at our disposal. I do not, therefore, wish the following to be considered anything more than an empirical method of solving various problems connected with the condensation of hydrochloric acid, such method being based upon the best experimental researches at present available.

There are three researches of great importance to this subject.

The first research is one by Hammerl, on the specific heat of aqueous hydrochloric acid. The amount of heat needed to heat aqueous hydrochloric acid is less than that which would be needed to heat the pure water contained in the liquid acid. For all acids between 10° and 32° on Twaddel's

hydrometer, the amount of heat necessary to heat such an acid one degree is almost exactly 7 per cent. less than that needed to heat, in the pure state, the water contained in the acid. Thus, all such acids require 0.93 units of heat for raising by one degree the temperature of a quantity of acid containing 1 grm. of water. Hammerl makes use of a complicated formula for calculating the specific heat, but that formula is useless for practical applications, and the above statement expresses the facts found by Hammerl with sufficient accuracy for technical purposes.

The second research I have to mention is one by Berthelot, on the heat developed by the solution of hydrochloric acid gas in water.

Berthelot finds that when 36.5 grms. of hydrochloric acid dissolve in 3,600 grms. of water (200 molecules to one molecule HCl) 17,430 grm. units of heat are evolved. An acid containing 36.5 HCl in 3,600 grms. H₂O is of about 1 per cent. or 1 Tw. If 36.5 grms. of hydrochloric acid gas are dissolved in less water less heat is evolved, and Berthelot gives the following formula, for the heat generated when a concentrated acid containing *n* molecules of water is diluted until it contains 200 molecules of water on one molecule of HCl, viz.:—

$$\text{heat liberated} = \frac{11,620}{n}.$$

But this formula again is, though extremely simple, not well adapted for our purposes, and I have changed it into another one which gives the amount of heat liberated when *x* grms. of hydrochloric acid are dissolved in 1 grm. of water. This formula is:—

$$\text{Grm. units heat liberated} = 477.5 \times x - 157 x^2.$$

And combining this result with the last one we find the rise of temperature if *x* grms. of hydrochloric acid are absorbed in 1 grm. of water to be—

$$\text{Rise of temperature} = 513 x - 169 x^2 \text{ in degrees C.}$$

The following table I have computed in order to facilitate calculations. The usual mode of expressing the strength of hydrochloric acid in this country is by indicating its specific gravity on the Twaddel scale. It so happens that the number of degrees on Twaddel's hydrometer almost exactly represents the percentage of hydrochloric acid. But for my purpose it is more convenient to express the strength of acid by saying that 1 grm. of water contains *x* grms. of hydrochloric acid. The table shows for any percentage of acid: 1st, the grms. of HCl on 1 grm. of water; 2nd, the units of heat evolved; 3rd, the rise of temperature during its formation.

TABLE I.

HCl.	Grm. HCl pro 1 Grm. H ₂ O.	Units of Heat Generated per Grm. of H ₂ O.	Rise of Temperature.
Per Cent.			°
5	.053	24.8	26.6
6	.064	29.9	32.1
7	.075	34.9	37.5
8	.087	40.4	43.4
9	.099	45.7	49.1
10	0.111	51.0	54.8
11	0.124	56.8	61.0
12	0.136	62.0	66.6
13	0.149	67.7	72.8
14	0.163	73.7	79.2
15	0.176	79.2	85.1
16	0.190	85.0	91.4
17	0.205	91.3	98.1
18	0.219	97.0	104.3
19	0.234	103.1	110.8
20	0.250	109.6	117.7

TABLE I.—*continued.*

HCl.	Grm. HCl pro 1 Grm. H ₂ O.	Units of Heat Generated per Grm. of H ₂ O.	Rise of Temperature.
Per Cent.			°
21	0.266	115.9	..
22	0.282	122.2	..
23	0.299	128.7	..
24	0.318	136.0	..
25	0.333	141.6	..
26	0.351	148.3	..
27	0.370	155.2	..
28	0.388	161.6	..
29	0.408	168.7	..
30	0.428	175.6	..
31	0.449	182.8	..
32	0.470	189.8	..
33	0.493	197.2	..
34	0.515	204.3	..
35	0.538	211.5	..
36	0.562	218.8	..

On glancing over this table, we are struck at once by the enormous amount of heat generated by the condensation of the hydrochloric acid. Supposing we had to convert 1 lb. of water into liquid acid of 28° Tw., which acid would contain 28 per cent. of HCl, the table shows that 0.388 lb. of HCl gas would be required, and that so much heat would be liberated as would heat 161.6 lb. of water by 1° C.

If we brought into contact water of 15° C. with pure hydrochloric acid gas of 15° C., the temperature of the liquid would rapidly rise, and would reach the boiling point 110° when 0.20 lb. of HCl has been absorbed for every 1 lb. of water. Such an acid would be of about 15° to 16° Tw. at ordinary temperature. According to this table then, the boiling point would be reached when the acid contains from 15 to 16 per cent. of HCl. The condensation of hydrochloric acid would not, however, cease; it would continue until the acid contains more than 20 per cent. of acid, the heat liberated by the condensation would no longer raise the temperature, but would simply cause the evaporation of some water.

Thus the result of bringing into contact cold water and cold hydrochloric acid gas under circumstances when no heat can escape would result in an acid of about 20° Tw.

It is very interesting to compare with this result another one, viz., that of bringing into contact cold water with hot hydrochloric acid gas. Let us assume the temperature of the hydrochloric acid very high, higher than any usual in practice, say 500° C. In that case each gram. of HCl gas brings with it $0.18 \times 500 = 90$ units of heat, which will help to heat the solution of the acid, and the total heat evolved will be increased to: $H = 477.5x - 157x^2 + 90x$, or: $H = 567.5x - 157x^2$.

Whilst cold hydrochloric acid evolves per 1 gram. HCl 477 units of heat, red-hot hydrochloric acid gas evolves 567 units or only 18 per cent. more heat. In other words to condense red-hot hydrochloric acid requires the removal of only 18 per cent. more heat than the condensation of hydrochloric acid of low temperature.

I have purposely chosen this high temperature in order to show how under certain circumstances previous cooling of the gas is of very little practical importance. *The great amount of heat to be removed is only generated when and where the gas comes into contact with water.*

The next research I have to mention, is that of Messrs. Roscoe and Dittmar. This is the most important research of all, because it furnishes us with the leading data for a theory of the condensation of hydrochloric acid. Though Messrs. Roscoe and Dittmar's research has been published a

quarter of a century, and ought to be well known, I will shortly recapitulate its essential points.

Messrs. Roscoe and Dittmar determined first the amount of hydrochloric acid which 1 gram. of water would absorb at 0° C., and under pressures varying from $\frac{1}{25}$ to 2 metres of mercury, and thus furnished us with a series of experiments from which we learn the influence of variations in pressure.

2nd. They also determined the amount of hydrochloric acid which 1 gram. of water would absorb under ordinary atmospheric pressure, but at various temperatures. From this series it is possible to find how the absorption varies with temperature, when the pressure remains constant, after applying a certain correction, which Messrs. Roscoe and Dittmar omitted, viz., a correction of the pressure for the partial pressure of water vapour at these various temperatures.

Messrs. Roscoe and Dittmar could not apply such a correction, because there did not exist at the time a table of the tension of aqueous vapour in presence of hydrochloric acid gas, nor has there been one supplied since to my knowledge. But it is possible to obtain such a table from the further determinations which Roscoe and Dittmar published in the same paper.

They determined the pressures, the boiling points, and the composition of hydrochloric acid, which distilled unaltered in composition, i.e., of which the vapour tensions can be calculated from the known composition of the residual acid. The experimental data supplied by Roscoe and Dittmar give us directly the highest possible tension of aqueous vapour in presence of hydrochloric acid gas at temperatures from 60° upwards. For temperatures below 60° we have also from Roscoe and Dittmar's researches, at least the ratios of the partial pressures of steam and hydrochloric acid into air, and by means of an ordinary table of the tension of aqueous vapour and the data furnished by Roscoe and Dittmar, it is possible to construct a table of the tension of aqueous vapour in presence of hydrochloric acid gas, which, if it is not perfectly accurate, is quite sufficient for technical applications. Roscoe and Dittmar gave the composition of acids which had been treated with large volumes of air at different temperatures, until the further application of air produced no alteration in the composition. It was found that at one and the same temperature an acid treated by air had the same composition as the acid boiling under diminished pressure at that temperature, a fact which proves that the partial pressures of steam and hydrochloric acid are independent of the presence or absence of atmospheric air. In consequence of this fact a table for the tension of aqueous vapours in presence of hydrochloric acid gas as deduced from Roscoe and Dittmar's researches is applicable also for gases containing atmospheric air.

I subjoin here a table thus constructed with considerable care from Roscoe and Dittmar's experimental results, supplemented by a few experiments of my own.

TABLE II.—MAXIMUM TENSION OF AQUEOUS VAPOUR (IN PRESENCE OF HYDROCHLORIC ACID) IN MILLIMETRES MERCURY.

t °	Maximum Tension of Aqueous Vapour.	Minimum Tension of Hydrochloric Acid.	t °	Maximum Tension of Aqueous Vapour.	Minimum Tension of Hydrochloric Acid.
0	3.2	0.52	60	79.0	11.8
5	5.0	0.81	65	103	15.0
10	7.2	1.16	70	130	18.6
15	9.8	1.65	75	164	23.0
20	12.8	2.0	80	205	28.4
25	16.6	2.6	85	254	4.6
30	21.0	3.3	90	313	42.0
35	26.5	4.1	95	386	50.7
40	32.8	5.0	100	472	60.8
45	40.0	6.0	105	574	72.5
50	50.0	7.5	110	676	84.0
55	63.0	9.3			

The figures in this table have the following meaning. Any gas saturated with aqueous vapour, but containing hydrochloric acid gas, the partial pressure of which is at least that given in the table, cannot hold more aqueous vapour than that corresponding to the partial pressure given in the table under the heading "maximum tension of aqueous vapour."

The first fact that strikes us on comparing this table with an ordinary table of the tension of aqueous vapour, is that much less steam can exist in hydrochloric acid gas than in other gases at the same temperature. Thus, for instance, at 100° C. the ordinary vapour tension is 760 mm., whilst in this table it is only 172 mm.

This explains the behaviour of hydrochloric acid gas escaping into damp air. Almost half the moisture of the air is at once precipitated as fog when hydrochloric acid gas is mixed with the air.

That the tension of aqueous vapour in hydrochloric acid is much less than given by ordinary tables I have frequently had opportunity to observe. I have often analysed mixtures of air, hydrochloric acid and steam, and seldom have I found even as much water as corresponds to the table given above. The amounts given there are maximum amounts.

I must also add that the mere fact that drops of liquid acid deposit from a gaseous mixture is no proof that the gas is fully saturated with moisture.

Temperature alone never can be used with certainty as an indicator of the amount of moisture in hydrochloric acid gas.

The following examples will show this:—

(1.) Ordinary pot-gas cooled to 62° C. contained:—

Air	57.2
HCl	31.2
H ₂ O	11.6
	<u>100.0</u>

Mm.

Partial tension of water vapour by analysis .. 88

" " " " by table... 91

(2.) Ordinary pot-gas cooled to 44° C. contained:—

Air	51.7
HCl	43.3
H ₂ O	5.0
	<u>100.0</u>

Mm.

Tension of aqueous vapour by analysis ... 38.0

" " " " by table 38.6

(3.) Hydrochloric acid gas dried by sulphuric acid, temperature 50° C.:—

Air	77.1
HCl	20.5
H ₂ O	2.4

Mm.

Tension of aqueous vapour by analysis 18

" " " " by table 50

This gas deposited acid of 32° Tw., though not saturated.

(4.) Gas evolved at 22° C.

This gas deposited acid of 36° Tw.:—

Air	83.66
HCl	14.73
H ₂ O	1.71

Mm.

Tension of aqueous vapour per analysis... 13.4

" " " " per table 14.2

The gas, dried by means of sulphuric acid, containing only one-third the amount of water corresponding to the table, still deposited liquid acid. It will also be seen that the other examples of gases saturated with moisture fairly agree with this table.

The use of this table in practice is chiefly confined to calculating the alterations which a given mixture of gas will undergo on cooling, and, if we combine the results with the information given in Table I., we can calculate the

amount of work which is done by a set of cooling pipes, as compared with the work which the condenser has to do. We can also by means of this table show the influence which the admixture of air has on the condensation.

When steam and hydrochloric acid condense together, a great amount of heat is evolved, which serves to keep the temperature of the gas up for a long time. It requires, therefore, a considerable length of cooling pipes to lower, by any considerable amount, the temperature of a hydrochloric acid gas containing steam.

The heat given out by the condensation of water vapour and hydrochloric acid to liquid acid of 25° Tw. is, per gram. of water, at least $536 + 141.6 = 678.2$ units, or 678.2 units pro 0.333 gram. HCl thus condensed. Thus the heat given out by 1 litre of HCl gas condensed will serve to heat nearly 10,000 litres of gas by 1° and prevent its cooling.

In his report of 1866, Dr. Angus Smith says (page 37):—"The cooling of the gas before entering the condenser is an extremely important point, so important that it may be said to be the key to all good condensation. It demands the most careful attention of the alkali makers."

He then gives a number of tables showing the temperatures of hydrochloric acid gas at various distances from the pan in which the gases had been evolved. As one striking example of the slow cooling of hydrochloric acid gas, I give the following series from Dr. Angus Smith's reports:—

Gas at pot.....	° F.
" 8 ft. from pot.....	324
" 16 "	295
" 24 "	288
" 32 "	230
" 40 "	188
" 48 "	187
" 56 "	185
" 64 "	182
" 72 "	176
" 80 "	172
" 88 "	171
" 96 "	160
" 104 "	168

If this had been a case of ordinary cooling the temperatures would have decreased much faster, but it was evidently a case of condensation and evolution of heat, and the decrease of temperature does not directly give any idea of the work actually done by such pipes.

At Messrs. Gaskell, Deacon, and Co.'s works, we have frequently measured with great care the amount of condensation taking place in such pipes.

From a charge of 16 cwt. of salt containing 10 per cent. of water, with the necessary amount of sulphuric acid of 132° Tw., there were evolved—

702.7 lb. HCl } in the pan and { 359 lb. HCl } in the furnace.
509.0 lb. water } 160 lb. water }

The gas from the pan passed through a length of 360 feet of earthenware pipes and was cooled down to 50° C. before entering the condenser. The acid condensed in the pipe was collected, weighed, and analysed, and amounted to 633 lb., containing 201.6 lb. of HCl = 28° Tw. Thus the cooling of the gas involved the dissipation of the following amount of heat:—

For condensation of 431.4 lb. water: $431.5 \times 536 = 231,616$	
" " " " to 28° Tw. acid .. 69,822	
Total units.....	<u>300,838*</u>

The amount of work left to be done by the condenser amounted therefore to the condensation of 501.1 lb. HCl and 78 lb. of steam, or in units of heat—

For condensation of 78 lb. steam	41,808
" " " 501 lb. HCl	192,884
	<u>234,192</u>

* Or approximately 2 units per square foot per hour per degree difference of temperature inside and outside

From these figures we see the great importance of previous cooling of the gas, the cooling pipes in that case having done 56 per cent. of the total condensation, as measured by the heat dissipated. We have made a great many such measurements, they are all very similar and they clearly demonstrate that previous cooling in the case of a gas containing steam is of great assistance.

Almost identically similar results as those found by direct measurement can be calculated by means of the table of tensions I have given, if we know the composition of the gas at any particular stage.

For if the volume V_0 of a gaseous mixture of hydrochloric acid, air, and steam containing x volumes of steam be cooled down to a certain temperature, then steam and hydrochloric acid will condense together in such proportion that for every 6 volumes of steam which condense, approximately 1 volume of hydrochloric acid condenses with that steam, and the remaining volume V_1 is saturated with moisture, and will contain x_1 volumes of steam such that $\frac{x_1}{V_1} = \frac{t}{760}$, where t = tension as given in the table. The amount of steam condensed would therefore be $V_0 x_0 - V_1 x_1$, and the amount of hydrochloric acid gas condensed would be $\frac{1}{6}$ of that or $\frac{V_0 x_0 - V_1 x_1}{6}$, and these two amounts account for the whole diminution of the volume, so that—

$$\frac{1}{6} (V_0 x_0 - V_1 x_1) = V_0 - V_1$$

from which equation we find—

$$V_1 = V \left(\frac{6-7x_0}{6-7x_1} \right).$$

The fraction of steam which was not condensed would be represented by—

$$\frac{V_1 x_1}{V_0 x_0},$$

or by—

$$\frac{x_1}{x_0} \cdot \left(\frac{6-7x_0}{6-7x_1} \right),$$

and the fraction of steam condensed would be represented by—

$$\frac{x_0 - x_1}{[1 - 1.166 x_1] x_0},$$

and x_1 is always = $\frac{t}{760}$, i.e., the tension given in the table divided by the barometric pressure at the time.

An example will make the application of the formula clearer. At Messrs. Gaskell, Deacon, and Co.'s works a charge of 16 cwt. of salt containing 8 per cent. of moisture, or 143 lb. of water, was treated with 1,858 lb. of sulphuric acid containing 423 lb. of water. The total amount of water is therefore 566 lb. Of this amount 500 lb. were evolved in the pan together with 700 lb. of HCl. If no air were present, and the gas were cooled down to 50° C., the amount of steam condensed during cooling would be found thus. The relative volumes of equal weights of hydrochloric acid gas and steam are nearly as 1:2 ($\frac{1}{36.5} : \frac{1}{18}$), or by bulk on 700 HCl there would be 2×500 of steam. The total bulk would be represented by 1,700, and the steam by 1,000, consequently $x_0 = \frac{1,000}{1,700} = 0.588$.

Then the table gives the tension at 50° C. as 50 mm., consequently $x_1 = \frac{50}{760} = 0.066$, and the fraction of steam condensed would be—

$$\frac{0.588 - 0.066}{[1 - 1.166 \times 0.066] 0.588} = \frac{0.522}{0.923 \times 0.588} = \frac{0.522}{0.543} = 0.961$$

so that 96.1 per cent. of the steam would condense in cooling down to 50° C.

But we can never entirely exclude air from these gases, and the more air there is present, the less effective previous cooling becomes as an aid to condensation. If, for instance, the gas evolved from the pan had been mixed with the gas from the furnace, and so much air had been present that only 150 grs. of HCl would be found on 1 cubic foot of air, or in round numbers 5 of air to 1 vol. of HCl, the gaseous

mixture would have had the following composition when leaving the furnace:—

HCl	14.1
H ₂ O	15.1
Air	70.8
	<hr/> 100.0

and x_0 of our formula would be = 0.206. We should therefore have when cooled to 50° C.

Percentage of steam condensed—

$$\frac{0.151 - 0.066}{[1 - 1.166 \times 0.066] 0.151} = 61 \text{ per cent.}$$

very much less than in the previous example.

In the first practical example I gave of an actual measurement, the amount of the steam condensed on cooling to 50° C. was 84.5 per cent., a result standing in between the two examples I have just calculated. In that case the composition of the gas was actually—

HCl	18.3
H ₂ O	27.0
Air	54.7
	<hr/> 100.0

From which composition the formula above calculates a condensation of 418 lb. of water, whilst 431 were actually condensed.

Considering the examples I have brought to your notice so far, I must modify the words of Dr. Angus Smith, and say that in the case of a hydrochloric acid gas containing much steam and little air, previous cooling is the key to good condensation, but with a gas containing little or no steam, previous cooling has not the importance which Dr. Smith ascribed to this operation generally.

Thus far I have dealt with the effects of previous cooling, and have shown how, by means of the table of tensions given, these effects can be ascertained by calculation.

There has been controversy as to whether previous cooling was really an advantage. I have already quoted Dr. Angus Smith. Opposed to his views are those of M. Schlösing, who thinks that the condensation of gases is more perfect when they are brought into contact with the condensing liquids while still hot. Professor Lunge, on the other hand, strongly opposed Schlösing, and supported the views of Dr. Smith. I think that if each of the authorities had stated exactly the conditions of the gas they proposed to cool, their opinions would not be found to differ materially.

I now pass on to a question which is of great interest to the manufacturer. It is the question, what is the highest strength of acid which can be produced from a gas of a given composition, under given circumstances as regards temperature, &c.

It has not been possible to answer that question hitherto with any degree of certainty. In a general way manufacturers knew what they had to do if they wanted strong hydrochloric acid. In a conversation I had with a friend on this subject, he said: It is surprising how much less water you have to put on the condenser to bring acid of 28° Tw. up to 30° Tw., this is also an important question.

To be able to answer such questions by calculations, we must know exactly how the amount of hydrochloric acid which 1 grm. or 1 lb. of water can absorb varies with the temperature and with the partial pressure of the gas. Such experiments have indeed been made by Messrs. Roscoe and Dittmar, but only under circumstances which do not occur on the large scale.

They made a series of experiments at freezing point with pure hydrochloric acid in order to ascertain how the absorption differed when the pressure was altered, but they did not repeat these experiments at any other temperature. They also determined the difference in the amount of HCl which 1 grm. of water could absorb at ordinary barometric pressures, the temperatures varying from 0° to 60° C. In these experiments the pressures of the hydrochloric acid were not, however, corrected for the tension of aqueous vapour, as is erroneously stated in some books, and this important series of experiments represents therefore not the results of variation of temperature only, but the result

both of variation of temperature and considerable variation of partial pressure of the hydrochloric acid gas.

That series of experiments which I have alluded to in the first part of my paper, concerning the composition of acids of constant boiling points, may also be considered as special cases of absorption, at varying temperatures and varying partial pressures of hydrochloric acid gas.

But all these experiments, so to say, represent extreme conditions, such as do not occur usually in the works. The conditions obtaining on the large scale lie between, and sometimes outside, the various conditions under which Messrs. Roscoe and Dittmar made their observations and performed their valuable experiments. The chief reason why no experiments have been made under conditions similar to those existing in works, I think, is this: those conditions are so difficult to imitate on a small scale as to entirely place such experiments out of question.

Under these circumstances, the only course open to us is to attempt to find a simple empirical formula which expresses the amount of HCl absorbed by 1 gm. of water as depending upon temperature and partial pressure of the hydrochloric acid, such a formula as would, with some degree of accuracy, reproduce the various series of experimental results ascertained by Roscoe and Dittmar.

Such a formula, which would calculate approximately all the results of Roscoe and Dittmar, would, with a high degree of probability, also calculate the amounts of hydrochloric acid absorbed under conditions intermediate, and such a formula, if simple enough, might prove very useful in practice.

I have, after many attempts, decided on the following simple formula as best adapted for practical purposes:—

$$C = [0.3040 - 0.0016 t] P^{0.150}$$

In this formula C represents the grms. or lb. of hydrochloric acid which 1 gm. or 1 lb. of water will absorb when the absorbing liquid has the temperature t , and is in presence of hydrochloric acid gas of partial pressure, P expressed in millimetres of mercury.

For convenience of calculations, I have constructed the following Table III. of the values of $[0.3040 - 0.0016 t]$.

TABLE III.—VALUES OF $0.3040 - 0.0016 t = C$ FOR DIFFERENT TEMPERATURES.

t .	C.	t .	C.	t .	C.
0	0.304	40	0.240	80	0.176
5	0.296	45	0.232	85	0.168
10	0.288	50	0.224	90	0.160
15	0.280	55	0.216	95	0.152
20	0.272	60	0.208	100	0.144
25	0.264	65	0.200	105	0.136
30	0.256	70	0.192	110	0.128
35	0.248	75	0.184		

I also append Table IV., giving the values of $P^{0.150}$ for gases under atmospheric pressure, and containing various amounts of hydrochloric acid.

TABLE IV.—VALUES OF $P^{0.15}$ IF THE BAROMETER STANDS AT 760 MM. AND THE GAS CONTAINS PER CENT OF HCl.

Per Cent.	$P^{0.15}$	Per Cent.	$P^{0.15}$	Per Cent.	$P^{0.15}$
5	1.725	40	2.357	75	2.530
10	1.915	45	2.400	80	2.615
15	2.035	50	2.438	85	2.639
20	2.124	55	2.473	90	2.662
25	2.197	60	2.505	95	2.684
30	2.257	65	2.535	100	2.705
35	2.311	70	2.564		

By means of these two tables it is easy to calculate, for any condition as to temperature and pressure, the amount of hydrochloric acid which 1 gm. of water will absorb, and when that is known, we find by Table I. the corresponding strength of the acid in per cent. or degrees Tw.

An example will make the use of these tables clearer.

(1.) Given pure hydrochloric acid gas at freezing point, how much hydrochloric acid will water absorb at ordinary barometric pressure?

From Table III. we find C for 0° to be 0.304, this we multiply by the value of $P^{0.15}$ for hydrochloric acid of 100 per cent. in Table IV. = 2.705, the result is 0.822 gm. of HCl absorbed by 1 gm. of water, or 0.822 lb. of HCl absorbed by 1 lb. of water.

(2.) A gas containing 25 per cent. HCl is in contact with a liquid hydrochloric acid at a temperature of 50° C., and ordinary barometric pressure, what strength will that liquid acid ultimately become, the temperature being kept constant?

We find in Table III. the value for temperature $50^\circ = 0.224$, and in Table IV. the value for 25 per cent. HCl = 2.197; multiply these two, and the result, 0.492, gives the amount of HCl absorbed by unit weight of water. Consulting Table I., we find that 0.492 corresponds to nearly 33 per cent. HCl or to 33° Tw.

In this way, a simple multiplication will give the desired result. For intermediate pressures and temperatures, the formula itself must be employed; it is readily applicable with the use of logarithms. It may be useful to give one example more.

(3.) What will be the strength of acid depositing from a gas of the following composition:—

HCl.....	43.3
H ₂ O.....	5.0
Air.....	51.7
Temperature.....	43° C.
Barometer.....	735 mm.

In order to find the value of the partial pressure of the hydrochloric acid, we multiply 735 by 43.3 and divide by 100, the result, 318.25, is the partial pressure in millimetres of mercury of the hydrochloric acid gas. We must now find the value of $318.25^{0.15}$. In an ordinary logarithm table we find $\log. 318.2 = 2.50270$, and multiplying by 0.15 we obtain 0.37540. The number to this latter logarithm is 2.373.

We now find the value of $0.3040 - 0.0016 \times 43^\circ$ to be $0.3040 - 0.0688 = 0.2352$.

Multiplying 0.2352 by 2.373 = 0.558 is the desired amount of HCl which will be condensed with unit weight of water. Consulting Table I. we find the corresponding strength to be between 35° and 36° Tw.

I have chosen this example to show the mode of applying the formula. I will not go into further calculations, but simply state that a gas containing 20.5 per cent. HCl gave at a temperature of 122° F. actually a liquid acid of 32° Tw., while the calculation would demand 32.9° Tw. (other examples follow below).

I have, in most cases to which I have applied the formula, found it to answer within one degree on Twadell's hydrometer. The greatest error I have found was in calculating an extreme case, viz., one of Roscoe and Dittmar's experiments at 0° and 0.05 m. mercurial pressure, where the error is 2° Tw.

So far then we are enabled, by means of the four tables I have supplied, to calculate the alterations which may happen during the cooling of the gas, the evolution of heat, the amount of condensation, and the strength of the acid formed at any temperature, and it only remains now to show the application of the formula to the condensing apparatus in ordinary use in this country, viz., the coke tower. These towers are usually built of stone, and the first difficulty we have to meet is the question how much heat does stone-work dissipate, for clearly the work which a condenser can do depends upon that, since the condensation means simply abstraction of heat.

In Box's treatise on heat we find that for 1 difference of temperature a stone wall 6 inches thick, 40 feet high, will dissipate per square foot 0.261 units of heat (British) per

hour. From Ferrini's technology of heat I calculate for similar conditions a very similar figure. But these figures are of no use, and in order to realise the work done by a stone condenser we must in the first case appeal to experiment.

A condenser 40 feet high, 8 feet \times 8 feet, has a vertical surface of 1,280 square feet. Into such a condenser there passed at Messrs. G. D. and Co.'s works in two hours 840 lb. HCl and 216 lb. of steam. The gas was mixed with air, the air leaving the condenser being 3 cubic feet per second = 1,720 lb.

The gas entered at a temperature of 73° C. and left at 60° C.

The condenser was fed with 2,520 lb. water in two hours, flowing in at a temperature of 15° C., and leaving as acid of 25° Tw. (measured cold) at a temperature of 80° C.

From these data we have—

(1) Units of heat entering condenser:—

Air 1,720 lb. at 73° C., specific heat 0.23.....	28,878
HCl 840 lb. " " 0.18.....	11,037
Steam 216 lb. " " 0.48.....	7,560
Total.....	47,475

(2) Units of heat carried away by gas leaving condenser:—

1,720 lb. air at 60° specific 0.23.....	21,958
Saturated with steam = 260 lb. at 60° \times 0.48....	7,388
+ latent heat of 44 lb. steam.....	23,584
Total.....	53,020

(3) Units of heat generated within condenser by condensation of HCl to 25° Tw. pro 1 lb. water 11.6 units, or for—

$$2,520 - 44 = 2,476 \text{ lb. water} \dots\dots 350,601$$

(4) Units of heat carried away by hot acid flowing out at 80° C. the water entering at 15°—

$$2,476 \times 65 \times .93 = 149,674$$

If from the amount of heat generated we subtract that carried away by the hot acid, and that which the gas takes away more than it brings, we find that the condenser walls must have dissipated the remainder, viz., 195,282, or, per hour, 97,641, per square foot per hour = 76.3 units.

Taking the internal temperature of the condenser as that of the liquid within, and the outside temperature as 15°, we have as a result that one square foot of stone work dissipates 1.15 units per degree per hour. This result is nearly four times as large as that given by Box.

What we learn from this example taken from actual practice is, that for successful condensation it is necessary to provide ample cooling surface in that part of the apparatus in which the gas comes in contact with the condensing liquid, since it is the act of absorption which generates the great amount of heat.

The condenser in question only yielded acid of 25° Tw. If it were required to make under the same conditions acid of 30° Tw., we should have to use considerably less water.

In order to find how much water would have to be used, we must know at what temperature the acid may flow out at the bottom in order to come out at least as 30° Tw. acid. This calculation is not difficult by means of the tables I have given.

From Table I. we find that pro lb. of water 0.428 lb. of HCl are condensed to form 30° Tw. acid.

The gas entering the condenser contained in round numbers 20 per cent. by volume of hydrochloric acid, and Table IV. gives for this amount the value of the pressure coefficient as 2.124.

Dividing 0.428 by 2.124 we obtain 0.201 as the value of the temperature coefficient to which corresponds in Table III. a temperature of 65 degrees. Consequently, with gas of this description 30° Tw. acid can only be obtained if the temperature of the liquid acid does not exceed 65° C., or the temperature of the condenser itself must not exceed 65°. Disregarding the small difference of heat owing to alterations

in the temperature of the gas, we can say that the heat dispersed by the condenser, and that carried away by the liquid acid, must be equal to that generated by the condensation.

By Table I. the heat generated per lb. of water used for 30° Tw. acid is 175.6 units. That carried away is $65 \times 0.93 = 45.4$, consequently the condenser has to dissipate for every lb. of water $175.6 - 45.4 = 130$ units.

Taking the figure 1.15 per degree per hour per square foot, and the temperature difference as $65 - 15 = 40$, the condenser will dissipate 117,760 units in two hours. Thus we find that we may use $\frac{117,760}{130} = 906$ lb. of water.

These will condense 387.7 lb. of HCl, and the rest of 453 lb. would escape, and would require a post condenser to deal with it.

That brings me to the last example I wish to cite. Two condensers, such as described, readily give acid of 30° Tw. from the gas of two saltcake furnaces.

The amount of HCl entering in two hours is 520 lb. The gas contains on an average only from 10 to 15 per cent. HCl. It is conveyed through the two towers in succession, the weak acid of the second condenser being pumped on the first condenser.

The gas passes into the first condenser at 77° C., leaves at 38° C., and leaves the second condenser at 32° C.

The second tower is fed with 1,215 lb. water at 15° C., which flows out at 48° as 10°—12° Tw. acid, but cools to 26° C. before entering the first condenser, from which it flows as 30° Tw. acid at 49° C.

These figures are from actual observations. It is easily calculated that two such condensers are capable of doing that work. As already explained we find for a gas of 10 per cent. HCl the temperature at which 30° Tw. acid can be formed. We divide 0.428, the amount of HCl to be condensed with 1 lb. of water by the pressure coefficient corresponding to 10 per cent. gas, which is 1.915, the result, 0.223, gives the temperature coefficient to which corresponds in Table III. a temperature of 50° C., which closely corresponds with the observed temperature.

The temperature of the first condenser being 50° C., the outer temperature being 12°, it will dissipate 111,872 units of heat in two hours. The acid carries away $22 \times 0.93 \times 1,215 = 24,860$, so that we may generate within the condenser $111,872 + 24,860 = 136,732$ units. If we divide this figure by the amount of water, 1,215, we obtain 112.5 units of heat as possible to be generated in the first condenser per lb. of water flowing through it. Consulting Table I. we find that 30° Tw. acid would generate 175.6, deducting the 112.5 possible to be generated in this condenser, we obtain 63.1 units, which must be generated in the second condenser, and this corresponds by Table I. to 12° Tw. acid.

We see, therefore, that calculations made by these tables closely agree with actual work.

It must, however, be understood that the figure 1.15 cannot be considered applicable to all condensers as expressing the units of heat dispersed per square foot per hour per degree difference of temperature. I have reason to believe that condensers free on all sides will disperse a great deal more heat; the condensers here spoken of are not free on all sides.

It must also not be forgotten that with a very dilute gas, the sensible heat of the gas may be greater in amount than that evolved during the act of condensation. It will, therefore, be impossible to lay down any rule as to the desirability of previous cooling, the usefulness of which depends entirely on the constitution of the gas.

It is also a commercial question, viz., whether it is cheaper to disperse the heat by means of glass or clay pipes, or by means of large and well constructed coke condensers. The continental system of great numbers of Woulf's bottles offers the advantage of large and effective cooling surface for the absorbing liquid. On the other hand the coke tower is comparatively free from nuisance.

I will now shortly refer to another part of the subject, viz., the amount of HCl which an inert gas will carry away if it passes through liquid acid of a given strength. This is important sometimes. The maximum amount of HCl which

a gas will carry away from an acid of given strength can be ascertained by means of the formula—

$$C = [0.3040 - 0.0016 t] P^{0.15}$$

If the equation is solved with respect to P, we obtain—

$$P = \sqrt[0.15]{\frac{C}{0.3040 - 0.0016 t}}$$

The equation can easily be solved by logarithmic calculation. P is then the partial pressure of the hydrochloric acid into the inert gas, and $\frac{P}{760}$ will give the volume per cent. of HCl carried away by the inert gas. This problem is at present more interesting to Her Majesty's inspectors of alkali works than to the manufacturer. I will only say that if air were passed in fine bubbles through a deep column of liquid hydrochloric acid of 12° Tw., it would just carry away 0.20 grains of hydrochloric acid gas per cubic foot of air.

I have now shown how by means of Roscoe and Dittmar's, Hammer's and Berthelot's researches many problems connected with the cooling and condensation of gases containing hydrochloric acid can be solved arithmetically.

The key to good condensation is not only to be found in the previous cooling of the gas, but also in the cooling of the absorbing liquid.

DISCUSSION.

After a vote of thanks on the motion of Mr. A. Norman Tate, seconded by Dr. J. Campbell Brown, the discussion was adjourned until the January meeting.

Dr. HURTER, in replying to the vote of thanks, said that the subject was a very difficult one, and one which nobody had attempted to deal with. He could not find in literature any attempt to make such a calculation, yet it was a subject which frequently occurred in works. Hydrochloric acid was no longer the valueless substance it was considered 40 years ago, and they had to be more careful with it every day; and it was important to obtain it of as high concentration as possible. It was therefore necessary that they should thoroughly understand the working of the apparatus which dealt with that gas.

It was considered that time and surface of coke were the great factors in the condensation of hydrochloric acid; the examples and calculations would show them that a most important factor was the heat which was generated by the absorption of the gas in water. The paper attempted to show the part which previous cooling in pipes, and the part which the walls of the condenser played in dispersing the heat of condensation.

If the tables and calculations were not quite perfect, they were the best substitute he could give them for a really accurate scientific theory. The tables were constructed so as to save all labour and all mathematical understanding. Those acquainted with mathematics could of course translate the formulæ into figures, but he found that to many chemists such formulæ were inaccessible. The sooner, however, his tables were replaced by more accurate ones, the better. But some one must make a beginning, and he hoped that this beginning was worthy of a place in the Journal of the Society.

Obituary.

DR. QUESNEVILLE.

We are indebted to the *Chemist and Druggist* for the following particulars of the career of the late Dr. Quesneville, Editor of the *Moniteur Scientifique* :—

DR. QUESNEVILLE (GUSTAVE-AUGUSTIN), born in Paris on January 1, 1810, died in the same city on November 11, 1889. A favourite pupil of Vauquelin and Chevreul, he at first studied medicine, and took the degree of doctor in 1834, but soon returned to chemistry, his father's profession, and succeeded to Vauquelin in his chemical manufactory, at a time when chemistry and pharmacy were terms almost

synonymous. His contributions to science generally consisted of short and practical notes, among which may be noted those on the analytical separation of iron and manganese; preparation of binocide of barium, of pure oxide of cobalt, of volatile chlorides, and of oxide of uranium without ammonia carbonate; combinations of chromic acid and silica; bismuth in large crystals; and medical uses of oxygenated water. But the principal work of Dr. Quesneville was his publication of the *Moniteur Scientifique*, an important monthly especially devoted to chemistry, theoretical and applied. The periodical, whose editor, publisher, and manager he was at the same time, first appeared in 1840 under the name of *Revue Scientifique*, and in 1857 changed its name to the present one. About a fortnight before his death he gathered together all his co-labourers in a banquet to celebrate the *Moniteur's* half-centenary, and there announced that it was his intention to cease publishing the paper with the current year. Feeling unequal to further efforts, and unwilling to see the work of his life pass into strange hands, he preferred to stop while he still had it within his power. Consequently the November number of the paper was headed with a notice advising the readers that the December issue would be the last published, and requesting subscribers not to send money for further subscriptions. Dr. Quesneville had the reputation of being very independent and a little peculiar—an appreciation apparently borne out by his determination to sacrifice to an idea the goodwill, no doubt valuable, of a long established publication.

It was only at the last meeting of the Council of the Society of Chemical Industry that it was unanimously resolved to acknowledge by an appropriate letter the Council's sense of the services rendered to Chemical Industry by the venerable Editor of the *Moniteur Scientifique*.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in Dryers of Pulpy Moist Substances. A. Büttner and C. Meyer, Uerdingen, Germany. Eng. Pat. 13,369, September 17, 1888. 8d.

This apparatus is intended for the dessication of semi-fluid or pulpy substances, in three stages. The semi-fluid is first led through circuitous channels in the flue of a furnace, across the upper parts of which the hot gases are passing, and after partial drying and condensation therein, they reach an open trough provided with a longitudinal worm for mixing and transporting. At this second stage dry materials may be added, and, after mixing, the whole mass is delivered to the third part of the apparatus. This consists of a longitudinal metallic chamber, heated from below, in which two horizontal rotary beaters are placed side by side, and which throw the particles about. A strong current of air carries the dried powdery stuff towards the far end of the chamber, where it falls into a conveyor, which takes it away. All particles still containing moisture drop down between the beaters into the trough of a longitudinal worm placed along the bottom of the casing, and are conveyed back to the inlet end. There they are taken hold of again by the beaters, and the operation is repeated until such time as they are sufficiently dried to be carried away by the current of air.—B.

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows :—

If the price does not exceed 8d.	½d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " " 2s. 4d.	1½d.
" 2s. 4d., " " " 3s. 4d.	2d.

Improvements in and connected with Thermometers. R. Free, Manningtree, and H. J. Pierce, London. Eng. Pat. 14,683, October 12, 1888. 8d.

THE improvements are connected with thermometers, whereby they may be adjusted to any desired degree of heat, and caused to sound a bell, or otherwise give warning, when a certain temperature, previously determined, has been reached. The invention is specially intended for use in the drying of malt or other produce where it is desired to keep the heat within certain limits. Two mercury tubes are connected with electric bells, one tube and bell being intended to indicate a low temperature, and the other a high one. In the former case, so long as a rod is in contact with the mercury, the circuit of a relay battery is closed; but when it is broken by the sinking of the mercury from the rod, owing to a decrease of temperature, an armature drops and brings into operation another battery, which causes the bell to ring until the temperature is raised to the required degree, and the relay is again brought into action. If the temperature rise too high, the rod in the other tube is brought into contact with the mercury, and then closing the circuit, causes the other bell to ring until the temperature is reduced to the desired degree. The contact rods can be adjusted to any degree of heat.—E. S.

Improvements in Apparatus for Evaporating, Distilling, Refining, or Concentrating Liquids. T. Gaunt, New York, and E. H. Clapp, Boston. U.S.A. Eng. Pat. 16,335. November 14, 1888. 1s. 1d.

THIS invention relates to improvements in apparatus for evaporating liquids or for concentrating solutions, such as sugar, soda, and others. The improvements embrace the use of corrugated heated surfaces arranged vertically, over which the liquid to be evaporated is allowed to trickle or flow in a thin stream. The surfaces may be constructed of pipes arranged horizontally one above the other, and connected through their ends for the circulation within them of the heating medium, such as steam. The evaporating surfaces are placed within a casing which forms the receptacle for the vapour produced, whilst in the lower part the concentrated liquor may collect and be subjected to further heat applied to the bottom of the case. Several such evaporators may be combined for "multiple effect," and the vapour disengaged from the liquid in one evaporator may be used for heating the pipes of the next. The partly concentrated liquid may reach the next evaporator by gravitation, if the situation permit of such an arrangement, or the evaporators may be placed all on the same level and the liquid pumped or lifted from one to the other. The specification includes regulators for the supply and distribution of the liquid, separators for depriving the evolved vapour of moisture, and various modifications in the details and arrangements of the apparatus. The patent embraces eight claims, and is illustrated by seven sheets of drawings.—B.

Improvements in Filters. H. Roeske, Philadelphia, U.S.A. Eng. Pat. 7203, April 30, 1889. 8d.

THE filter, which is preferably of a cylindrical shape, has an outer and an inner chamber, each divided into compartments which communicate with each other by means of adjustable valves. Both chambers are partly filled with filtering material, that in the outer one being preferably gravel, sand, &c., and that in the inner chamber preferably coke in a granulated or crushed state. The liquid flows into the outer chamber through pipes provided with valves, and thence into the inner chamber, and through a connecting pipe into a central stand pipe which serves as the exit for the filtered fluid. In the outer chamber, and surrounded by the filtering material, are placed flushing and cleansing flues, preferably of a triangular form in cross section, and having their bases perforated. Pipes are also provided by which steam or hot water can be admitted into the inner chamber if required.

—E. S.

Improvements in Filtering Apparatus. C. B. Davis, Chicago, and E. H. Riddell, Cincinnati, U.S.A. Eng. Pat. 9651, June 11, 1889. 1s. 3d.

THE improvements consist in filtering apparatus adapted to the filtration of large quantities of water by passing the same under pressure through a bed of suitable filtering material contained in a closed tank, the object being to provide means for thoroughly washing the filter-bed without removing it from the tank, and with a minimum expenditure of time and water. For the mode by which this is effected, the specification, and the six sheets of drawings which accompany it, must be consulted. There are 15 claims.

—E. S.

Improvements in Filters. A. J. Boulton, London. From P. Varin, Bar-le-Duc, France. Eng. Pat. 9975, June 18, 1889. 6d.

THE filter consists essentially of a series of thin, juxtaposed metallic plates, the metal varying according to the nature of the liquid to be filtered. The plates are grooved in such a manner that chambers are formed both for the unfiltered, and filtered or clear liquid. Between every two plates is placed a sheet of filtering paper. The liquid to be filtered is introduced into one of the chambers, and fills the horizontal slots, but cannot enter into those of the other chamber, or that for the clear or filtered liquid, without first passing through the filtering medium. The plates are pressed together by suitable mechanism so that the whole is water-tight. The air contained in the chambers is driven out by the liquid itself; this is specially necessary in filtering liquids containing carbonic acid. The state of the process can be observed through indicator glasses. The plates and filtering papers can be cleaned by introducing clean water and reversing the flow of the current. The filter is mounted preferably on a three-wheeled carriage provided with two uprights into which the trunnions of the filter are placed, and can then be readily tilted if desired.—E. S.

Improvements in Apparatus for Use in Decomposing Chemical Compounds and Metallic Salts, and for Desulphurising Ores. H. H. Lake, London. From O. B. Peck, Chicago, U.S.A. Eng. Pat. 10,288, June 24, 1889. 8d.

THE inventor's idea is to mechanically separate the constituents of chemical compounds, such as metallic salts, sulphur ores, &c., by subjecting them in the molten state to centrifugal action. The vessel which he proposes to use for the purpose is by preference made in shape of a truncated cone, secured to the upper end of a vertical revolving shaft, and has a central opening at the top. Through this opening the molten material is poured in a thin central stream, whilst the lighter material of the compound subjected to centrifugal action rises and escapes all around the edge of the opening, and is caught in a surrounding casing. The heavier material remaining within and filling the cone after a certain time, can be removed by taking the cone to pieces, for which provision is made. The specification is illustrated by several drawings, and there are 13 claims relating to various arrangements and details of construction.—B.

Improvements in Pouring-in Funnels. W. Blakely, West Bournemouth. Eng. Pat. 12,290, August 2, 1889. 6d.

THE improvements are connected with funnels used in pouring oils or other liquids into jars or other receptacles. The improvements and claims are:—(1.) Fixing in any suitable manner on the inner surface of the funnel a series of downwardly projecting lips to prevent the splashing of the liquid when pouring in. (2.) Corrugating or fluting the spout of the funnel, or passing from the lower end of it to the top of the cone of the funnel, and fixing thereto a pipe, to allow the air to escape. (3.) Placing in the spout of the funnel a valve or float which indicates when the vessel is filled, and prevents overflowing. The float is

attached to a stem which moves in guides in the funnel, and has a loop at the upper end by which the funnel may be lifted so as to keep the valve closed and prevent the escape of the liquid whilst the funnel is being transferred from one vessel to another. (4.) Combining with the funnel a clamp by which it may be secured to the mouth of the vessel to be filled. (5.) Making the upper part of the funnel "half-moon-shaped" (in plan), so that it may be applied to the tilting aperture of lamps or similar receptacles without interfering with the globe or chimney.

—E. S.

Improved Evaporating Apparatus, Applicable for Cooling or Heating Liquids, and for Charging Gases with Vapours. R. Reichling, Dortmund, Germany. Eng. Pat. 13,212, August 21, 1889. 6d.

IN this invention the condensation of vapours or cooling of gases is sought to be accomplished by causing them to pass over moveable surfaces cooled by sprays of liquid. In one arrangement a number of corrugated discs are placed some distance apart, one behind the other, upon a hollow shaft, which is carried in the sides of the surrounding casing. The liquid issues in the form of spray through holes in the shaft between the discs, whilst the vapour passes across their surfaces as they rotate.—B.

II.—FUEL, GAS, AND LIGHT.

Gaseous Fuel. Sir Lowthian Bell. The Discussion. (This Journal, 1889, 761—764.)

MR. J. HEAD said there had been a great deal of confusion in the public mind with reference to water-gas. It was assumed, because this gas would give a higher initial temperature than producer-gas, that therefore it would be better. The real question was what was the loss of heat in the chimney; and, comparing the one gas with the other, the only difference was that the weight of the gases going up the chimney, at the same temperature in both cases, would be less in the case of water-gas than producer-gas. The difference for furnaces of water-gas, as compared with producer-gas, when everything was taken into account, was about 0.5 per cent. in favour of the former—that was to say, if they burnt 100 tons of coal with producer-gas, they might do with 99½ tons by using water-gas; and that was the only advantage. Another question was that of cost. He made a calculation for Mr. Siemens, based on the figures given by the friends of water-gas, and he found that, to melt two tons of steel and do a certain amount of other work, it would cost 18s. 3d. when using water-gas, and only 10s. 6d. with producer-gas.

MR. W. L. WILBY (Engineer to the Leeds Forge Company, Limited) said Sir Lowthian Bell had asserted that from 15 to 30 per cent. of the heat of the coal was employed in converting that coal into the gaseous form. From numerous records he found that the lower percentage was correct for producer-gas. In the author's calculations of the comparative calorific effect of producer-gas and the fuel from which it was made, he took credit for the whole of the carbon and hydrocarbons in the fuel, while it was well known that there was a large percentage of loss by condensation in the gas-tubes and flue; and that as for the producer-gas at the furnace showing a loss of 23.3 per cent., any number of analyses showed losses of from 30 to 40. Some of the figures relating to the foreign works were, while intended to be instructive, quite misleading. The most practical man admitted that gaseous fuel was the most perfect form of fuel known, from its easy applicability, control, and cleanliness. Yet the gases most usually employed showed a loss of at least 30 per cent. of the total heat-units in the fuel, and then gave a gas the flame of which was of far lower calorific intensity than the flame of water-gas, the proportion being 1,915 : 2,839. The detailed statement of the cost of production of water-gas at Witkowitz

was so extraordinary, and the cost per ton of gasifying the fuel so enormously high, that he could not but think that there must be some error, or that proper supervision had not been kept over the process. That it should cost 12s. 2½d. to gasify a ton of coal seemed enormous; and to steam a ton of fuel would decompose 980 lb. of water and produce 35,000 cubic feet of water-gas and 140,000 cubic feet of producer-gas. Therefore, to avoid steam for gas-making, 980 lb. of water were to be evaporated, to which might be added 980 lb. evaporated for engine purposes; making 1,960 lb., which, divided by 9, equalled 218 lb. of coal (or roundly, 2 cwt.), at 6s. The cost of fuel thus came to 7½d. instead of 3s. 6½d. Maintenance charges in the Moravian list were about three times what they would be in England. Having discussed this point, the speaker went on to deal at some length with Sir Lowthian's objection to the application of water-gas to the Siemens regenerative furnace; giving data respecting a comparison of mixed gases with solid fuel in the production of steel. He cited figures in disproof of the statement that coke at 36s. 5½d. per ton would produce heat as cheaply as water-gas; and contended that this sum should be divided by 2½ at least, bringing it down to 14s. 7.44d. The comparison of the producer-gas should, he said, be divided by 3 at least, bringing the value of the carbon in its original condition to 8s. 8d.—equal to coal of the quality taken at 7s. 5½d. per ton. He closed his remarks by pointing out that the quotations from Herr Kupelwieser in favour of producer-gas compared with water-gas were made in forgetfulness of a previous statement made by an official engineer of the Witkowitz works as to the advantages possessed by the latter gas.

MR. J. E. DOWSON remarked that in practice there was no general rule as to solid being more economical than gaseous fuel. In some cases it was better to have one, and in different circumstances the other. Gaseous fuel had the advantage—in the case of gas-engines, which were now being made of considerable power. He could speak with experience of engines which developed something like 1,500 horse-power; and the general result was that even when a small engine of about 10-horse power was used, the fuel consumption was only 1½ lb. per indicated horse-power, while in the larger ones it was 1½ lb. In the installation at Messrs. Spicer's paper-mill at Godalming, they employed gas power with "Otto" engines of about 240-horse power; and Mr. Spicer informed him that, after long working, he estimated that the fuel consumption was only about 1 lb. per indicated horse-power. Speaking generally, it might be, and doubtless was the case, that theoretically, solid fuel should give better results than gaseous fuel; but his contention was that in practice this was often not possible, and that for many purposes gaseous fuel was better and more economical, especially when the best appliances were used for getting as high a duty as practicable from the fuel.

MR. B. LOOMIS (Hartford, Conn.) said he had been largely connected with water-gas projects in America for many years. Producer-gas, to be effective, must be made and delivered under pressure, as an efficiency 30 to 35 per cent. better was obtained by pressure. Producer-gas, water-gas, and coal-gas should be made out of the cheap soft slack coals of the country. Actual demonstration and figures showed that they were able to make 40,000 cubic feet of water-gas, mixed with coal-gas, from a ton of bituminous coal. This mixture had about 350 heat-units per cubic foot, which was a very high calorific value. In the case of gas made from anthracite coal, it was 290 units; but from bituminous coal with more hydrogen in it, as well as some marsh gas, the heating power was increased to the extent he had mentioned. Producer-gas made from soft slack coal in properly built furnaces was far superior to the producer-gas or coke with a blast furnace; and it could be made entirely free from tar, as this might be converted into gas. Water-gas was being used for metallurgical purposes. At large works in Massachusetts, the entire forging was done at a saving of 30 per cent. of labour and nearly 50 per cent. of coal. Another works, near Boston, was entirely run with water-gas. In Cincinnati, gases were mixed together and used; and the cost of coal had been reduced more than half, and the time for drying the coal from 12 to 2 hours, besides the amount of labour that was saved.

MR. SAMSON FOX said he had many times found himself on the same side as Sir Lowthian Bell; but in the present matter he was ranged on an opposite platform. In supporting his contention, he did not rely on anything but absolute fact, the result of two years' experience in actual working. It was stated in the paper that water-gas would not give as good results as solid fuel. He could not deal with gaseous fuel generally; but he felt competent to speak as to water-gas. The author was wrong first of all in the cost of producing. In one place the paper said that 12s. 2½d. was the cost of gasifying a ton of fuel; and on the same page it was stated that the figures which the Leeds Forge gave were 2s. 8d. It was evident that one side or the other must be altogether wrong; and he would only remark that the 2s. 8d. was the result not only of their own calculations, but was deduced from figures taken out by entirely independent authorities. The cost of the fuel was also wrong, for in one place it was put down at 13s. 5d., and in another place at 10s. The paper said that coke was used by the Leeds Forge Company; and exception was taken to this because, if water-gas superseded ordinary gas, there would be no gas-works to go to for the coke. In reply to this objection, he would only say that they used coke because it was the most convenient form of fuel to be obtained; but it was to be remembered that this was a fuel out of which someone else had taken a large quantity of gas. In some works, however, there was a great quantity of breeze, which could be used just as well as any other material for making water-gas. Sir Lowthian was wrong in his estimate of the cost of steam, which he put down at 3s. 6½d. per ton of coal treated; this being according to the figures sent him from Germany. This item was included in the 12s. 2½d. charged to gasification. He (Mr. Fox) considered the estimate much too high, as he thought 6d. per ton of fuel would be sufficient to cover the item of steam required. Taking these three features—the cost of fuel, of gasification, and of steam—to be wrong, it would be found that the estimate of the author must be entirely recast in order to give a true idea of the commercial aspect of the question. As to the pressure at which the gas might be used, an instance was given in the paper, in which it was stated that as much water-gas was to be sent through a 1½-inch pipe as would be equivalent to ordinary gas passing through a 36-inch pipe. It should be explained that the gas was to be conveyed under considerable pressure. It had been arranged to supply a small town with water-gas for lighting purposes. Round this town were seven villages, lying at distances ranging between three and seven miles. The villages had arranged to take the gas if it could be conveyed to them. There was no difficulty in this, if the gas could be reduced in volume to an equivalent to 600 lb. pressure, so that small pipes and small gasholders could be employed. He hoped to do this in many cases; for there could be no doubt that, for general lighting, water-gas was better and cheaper than ordinary gas, and certainly very much cheaper than the electric light. At the Leeds Forge it had been used for 18 months; and he had had it in his own house for eight months. He found it in every way an advantage—first on the score of purity, but more especially in cost. The charge for ordinary gas with him was 3s. 9d. per 1,000 cubic feet, but he could supply the water-gas at 1s. 1d. Besides the many new openings there might be for utilising water-gas for manufacturing purposes in the future, within the next two or three months there would be a dozen plants at work which were now building. There were positions in which the new gas would be of the greatest value—such, for instance, as where ordinary gas would not be sufficiently clean. He concluded by inviting the author of the paper to visit the Leeds works, so that he might examine the whole process, and see for himself the carrying out of working details upon which his (the speaker's) estimates were based.

MR. E. RILEY asked Mr. Fox how he proposed getting over the difficulty of employing so poisonous a gas as carbonic oxide for the lighting of private houses—a gas, too, without smell.

MR. FOX said, in the first place, it might not be generally known that the larger part of the gas-piping in houses was in a leaky state at the present time, and that something like

25 per cent. of the amount of the gas bill was owing to the leakages existing throughout the country. Let them make thoroughly tight gas-fittings, and introduce into the gas a little volatile liquid that would give warning of a leakage the instant it occurred, and there would be no fear of injury resulting from an escape of gas. The percentage of carbonic oxide in water-gas was perhaps 0·45.

HERR KUPELWIESER said he wished to explain that at the time he wrote his first letter he gave about 13s. a ton for coke, whilst at another time, and taking an average, the price was 10s. 3d. a ton. At that price 1,000 cubic metres, or 35,316 cubic feet, of producer-gas would cost 3s. 1d., as against 1,000 cubic metres of water-gas at 11s. 6d., or 1,000 cubic feet at 4½d. This might be compared with 1,000 cubic metres of coal-gas at 3l., or 1s. 8½d. per 1,000 cubic feet. These prices were much the same as those given by Sir L. Bell, though arrived at differently. He wished to point out that the 1,000 cubic feet of steam, costing 3s. 6d., referred to German practice, and not to Witkowitz. The apparatus he used was similar to that adopted by Mr. Fox, and it had been working two years with satisfactory results.

SIR F. ABEL thought the Institute was much indebted to Sir Lowthian Bell, and also to Mr. Samson Fox, for the valuable information they had afforded on the subject of gaseous fuel. Water-gas itself was not used, pure and simple, for metallurgical purposes, but mixed with other gases. With regard to the danger from poisonous effects, he doubted if it would be wise to place their lives in the hands of the average gas-fitter, and admit a poisonous gas into their homes on the faith of his work being perfection.

M. POURCEL having made some few remarks, as representing France,

MR. F. SIEMENS said he had been much struck with Mr. Samson Fox's statement that he did not use water-gas pure for furnace purposes, but mixed it with the other gas made in the same apparatus. This practice would agree with his own experience in using gases; and as the resulting gas would be very similar to that made in the Siemens gas-producer, he could not see any advantage in the proposal to make two gases separately to be afterwards mixed. He had had a great deal of experience for a long period with various kinds of gases, using them for furnaces with which he had been experimenting; and the result of his experiments was to divide gases into two classes—luminous and non-luminous. He found non-luminous gases to be of very little use for furnace purposes, as they were only suitable when heating with contact. For incandescent gas lighting, for instance, the non-luminous gases could be used, as the flame struck upon the material which had to give the light. Non-luminous gases (to which class water-gas belonged) did not radiate light or heat sufficiently; and they could not therefore possibly heat large furnaces with them. They would be obliged to mix water with gas made from coal, or carburetted it in some other way, in order to use it in large furnaces. This would be a rather complicated operation. According to his (Mr. Siemens') experience, the presence of hydrocarbons in gas for furnace purposes was of the utmost importance. He read a paper a few years ago before the Institute, in which he stated that large furnaces could not be worked with non-luminous gases. If, however, water-gas was mixed with illuminating gas, as had been proposed by Mr. Fox, then, of course, it would do very well.

SIR L. BELL, in reply, said that he was at a loss to understand why Mr. Wildy and Mr. Fox should complain of the high price he had put on the fuel, for it was their object to show that the water-gas was cheaper than the solid fuel; and if the high price of fuel made the gas appear dear, it made the solid fuel dear also. The question was one of comparison. It was beside the question also whether coke or coal were used, from a scientific standpoint; the problem being whether, from a calorific point of view, a given amount of fuel could be used more advantageously in a solid state direct or by being previously gasified. He had seen water-gas in use at Frankfurt years before, and had come to the conclusion then—and this opinion he still held—that in some situations it would be good; but this was a very different thing from saying, as really seemed to be claimed for it,

that it would be suitable for all purposes. Exception had been taken to the construction he had put on the statement in the pamphlet as to the sizes of the pipes required to supply water-gas and the ordinary coal-gas. Mr. Fox had offered an explanation; but he (Sir L. Bell) would like to ask what power it was proposed to apply to force gas at 600 lb. pressure through a small pipe for 10 miles. For his own part he thought the friction would be so great that he should not be surprised if the pipe became red hot. Stress was laid on the fact that cheap water-gas could be made from breeze, which was a by-product of gasworks; but Mr. Fox proposed superseding existing gasworks by his system. Where, then would the breeze come from? As to the cost of converting solid into gaseous fuel, he himself had had some misgivings as to 12s. 2½d. being quite right until Mr. Kupelwieser spoke. Even the 2s. 8d. of Mr. Fox was, however, a heavy percentage on the price of coal or coke. In conclusion, he said he only desired to get at the truth of the matter. He should therefore gladly avail himself of Mr. Fox's offer to allow him to make a complete investigation at the Leeds works; and it would be found that, if he had been over bold in putting forward the statements in his paper, he would equally show his courage in acknowledging any errors he might have made.

Paris Gasworks' Experimental Data. The Gas World, 1889, 429.

THE following results have been obtained at the Paris gasworks during recent years, and are set forth in a report by M. Em. Sainte-Claire Deville:—

1. Those coals which contain most oxygen are those which most readily absorb and retain moisture. When the oxygen ranges from 5½ to 12 per cent., the latter ranges from 2·17 to 6·17 per cent.

2. The whole quantity of volatile matter in coal is greater the greater the percentage of oxygen. When the latter ranges from 5½ to 12 per cent., the former ranges from 26 to 40 per cent.

3. The quantity of carburetted volatile matter (after deducting the possible water) is also greater the greater the percentage of oxygen in the coal. The respective ranges are: oxygen, 5½ to 12; possible water, 6½ to 13½; carburetted volatile matter, 23·23 to 30·83 per cent. of coal free from ash.

4. There is no clear relation between the percentage of cinders and the analysis of the coal. Still, the least oxygenated (5 to 6½ per cent. of oxygen) and the most oxygenated (11 to 13 per cent.) coals contain most cinders, and the least cinders (rarely below 3 or 4 per cent.) are in the coals which contain from 6½ to 9 per cent. of oxygen.

5. There is no clear relation between the percentage of oxygen and the proportion of sulphur and chlorine. That depends on the geological stratum, and probably on the circumstances of deposit.

6. When a coal is distilled with its own coke the yield of gas is less in the most oxygenated coal, *because of the pooriness of its coke*. (Range = 10,641 cubic feet and 2,420° F., down to 9,691 cubic feet and 2,232° F.)

7. The more oxygenated coals are easier to distil; heated with their own coke they distil more uniformly than the less oxygenated, and at a lower temperature.

8. Carbonic acid diminishes lighting power by 2·73 per cent. for each per cent. of gas replaced by carbonic acid. (Date of research, September and October 1886. Agrees closely with Mr. Sheard—13/9/87—who says 2·69.)

Nitrogen, similarly, causes a loss of 1·8 per cent.

9. As we pass up from coal with 5½ to coal with 12 per cent. of oxygen, we find that in the analysis of the gas produced the carbonic acid rises from 1·47 to 3·13; the carbonic oxide from 6·68 to 11·93; the hydrogen sinks from 54·21 to 42·26; the marsh gas and nitrogen together rise from 34·37 to 37·14; the benzol rises from 0·79 to 1·04 (at between 9 and 11 per cent. of oxygen in the coal) and again sinks to 0·88; the other (non-aromatic) carburetted hydrogens rise from 2·48 to 4·66 per cent. Heating the coal by its own coke; temperature produced sinks from 1,326° to 1,222° C.

10. Under the same circumstances the density of the gas rises from 0·352 to 0·482, and the lighting power rises from 8·03 to 10·4 candles (assuming, that is, that the candle is 7·435 English candles) per 5 cubic feet of gas actually burnt per hour.

11. Under the same circumstances the amount of absolute lighting power obtainable from a metric ton of coal rises from 227 to 269 candles. This rise is not proportionate to the increase in volatile matter; the reason appears to reside in the presence of carbonic acid.

12. The most bulky coke is that from coal containing from 5 to 7½ per cent. of oxygen.

13. Coke from coal with 5 to 7½ per cent. of oxygen is good, though rather quick burning; 7½ to 9, small and dense, excellent; 9 to 11, mediocre or bad; 11 to 13, "detestable."

14. Weight of tar increases from 3·902 to 5·592 per cent. of the coal used; weight of liquor increases from 4·584 to 9·861 per cent.

15. The production of ammonia depends much more on the temperature, the season of the year, &c., than upon the nature of the coal; explained by the accumulation of ammoniacal salts in the coke towers in winter.

16. In coal from the same seam, the more oxygen, the greater the yield of ammonia.

17. In ordinary working the distribution of the impurities is:—

	NH ₃ .	HCl.	H ₂ S.	H ₂ Cy.	CO ₂ .
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Retained in condensers	63·1	96·3	8·1	3·3	9·8
" scrubbers (sawdust)	35·4	3·7	3·8	5·2	7·5
" purifiers (iron oxide)	1·5	..	88·1	91·5	Trace
Remaining in gas	Trace	Trace	82·7
	100·0	100·0	100·0	100·0	100·0

18. The best gas coals are those containing 7½ to 9 per cent. of oxygen. Less oxygen than this in the coal, there is plenty of coke but the gas is poor; more, the coke is bad.

19. As to the effect of the temperature of distillation, the Paris experiments of the last 12 years have simply confirmed the well-known statements that high temperatures (1) increase the volume; (2) diminish the density; and (3) lower the lighting power of the gas; (4) slightly decrease the carbonic acid (but not always so); (5) do not affect the proportion of carbonic oxide; (6) decrease the marsh gas; (7) diminish the percentage of heavy hydrocarbons, absorbable by bromine, other than aromatic hydrocarbons; (8) increase the hydrogen; and (9) decrease the yield in tar. The increase in volume is greater within limits than the decrease in lighting power; so that the ton of coal gives *more light*.

20. If the gas issuing from a retort be made to record its own yield by means of a pencil and rotating cylinder, the curve recorded presents a marked inflexion where the yield of gas becomes exhausted. If the heat be adjusted to suit the charge and the time, the yield is very steady until just before the end of the four hours. If the temperature be excessive, or if the coal be too highly oxygenated for the average heat applied, this inflexion is very strongly marked. If the temperature be inadequate, the inflexion is less well marked.

On the Recovery of Sulphocyanogen and Ferrocyanogen from the Spent Oxide of Gas Purifiers. J. V. Esop. Zeits. f. angew. Chem. 1889, 305—307.

See under VII., page 881.

Petroleum Supply of Baku. Board of Trade Journal, VII. 512.

A DESPATCH, dated the 22nd October last, has been received at the Foreign Office from Sir R. B. D. Morier, Her Majesty's Ambassador at St. Petersburg, enclosing an extract from the *Journal de St. Pétersbourg* of the 10th (22nd) October last, respecting the petroleum supply of Baku. The following is a translation of the extract in question.

The *Journal du Ministère des Finances* states that, contrary to the assertions of different foreign newspapers, the Caucasus naphtha industry is developing in a very satisfactory manner. Thus the Balakhani-Sabouutchinsk springs, which, it is said, are being exhausted, produced last year 173,472,226 pounds of naphtha. Compared with 1887, the production of these springs has increased by 15.1 per cent., and it may be observed that the production of 1887 exceeded by 12.1 per cent. that of the preceding year. It is a fact that since 1882 the production of naphtha at Baku has constantly increased, whilst it has gradually diminished in considerable proportions in the United States. Our contemporary makes on this head the following comparison of the average daily production of naphtha at Baku and in the United States:—

—	Baku.	United States.
	Pounds.	Pounds.*
1882	138,380	740,727
1883	165,410	570,024
1884	246,530	609,156
1885	318,510	512,289
1886	328,890	636,561
1887	415,000	531,603
1888	503,120	420,300

* A barrel of American naphtha is reckoned at the rate of 9 pounds.

Moreover, the stock of petroleum in the United States has fallen from 333 to 130½ million pounds, whilst at Baku, by reason of the construction of reservoirs, it is always increasing.

The *Journal* states, in conclusion, that there is still in the environs of Baku and in other localities of the Caucasus, a large number of springs of naphtha hitherto unworked, which is no longer the case in America.

The Turfa Mines of Brazil. United States Consular Reports, July 1889, 353.

CONSEL Burke, of Bahia, reports the discovery in that province of a mineral which has been called Turfa or Brazolina, and which furnishes an oil akin to petroleum, a paraffin suitable for the manufacture of candles, and a good lubricating oil. It was originally discovered by an English clergyman named Wilson, but a company has recently been formed which has bought the concession, and is now engaged in the development of the property. Petroleum extracted from it has already been placed on the market, and has been favourably received.—C. G. C.

Petroleum Discoveries in Netherlands-India. Board of Trade Journal, VII. 536.

THE *Deli Courant* states that search for petroleum along the banks of the Lapan river, in Langkat, has resulted in the discovery of large deposits of that oil. Raw petroleum oozes out of the ground at many places, where the natives have consequently dug pits. The output from most of the latter has never been considerable, and shows fluctuation. At Telaga Tunggal, where the boring reached a depth of about 350 feet, more important results have been arrived at. Appearances indicate that the main reservoir has been tapped there. The oil met with in the other pits and deposits proved to have found its way above ground from that storing place.

The oil tested yields 35 per cent. of lamp oil of good quality. It does not contain harmful ingredients, and offers advantages as a lubricator. The exact depth of the other deposits remains to be determined before an estimate of working expenses can be accurately made.

PATENTS.

Apparatus for the Manufacture of Gas. The Gas Patents Syndicate, Limited, London. From J. B. Archer, Washington, U.S.A. Eng. Pat. 8559, June 11, 1888. 8d.

This is a description of a somewhat complex apparatus for producing gas from steam and liquid hydrocarbon. An outer—containing an inner—retort is set vertically in a fire-flue leading upwards from a circular furnace below. A brick partition surrounding the central fireflue acts as a division wall between this and a second chamber through which the products of combustion have also to pass. In this chamber is set a series of retorts into which liquid hydrocarbon is drawn by steam, which has been superheated by passing first through a coil of pipes in the brick partition above mentioned, and then through a second coil situated around the retort in the central fireflue. After leaving what we may call the exterior retorts, the mixed gases enter the inner of the two central retorts, and traverse this from top to bottom, their passage being impeded by a number of perforated spherical segments forming horizontal partitions in the retort. Leaving the inner retort at the bottom, the gases pass upwards by the space between the two retorts, and leave the outer one at the top ready for use or storage.

—A. R. D.

Improvements in Steam Generator and other Furnaces. J. Fernee, Norton Woodseats. Eng. Pat. 11,643, August 13, 1888. 8d.

THE essential feature of this invention is that the gaseous products of incomplete combustion are taken from the fire-place to a combustion chamber situated overhead, where they are joined by a further supply of air heated by passing through a series of fireclay ducts, which communicate (through the firebars) between the combustion chamber above and an air space below. The invention is said to be specially applicable to marine and locomotive boilers.—A. R. D.

Improvements in Apparatus for Generating Illuminating Gas and Gaseous Fuel, and for Burning the Latter. O. Langberg, Brooklyn, U.S.A. Eng. Pat. 13,050, September 10, 1888. 1s. 1d.

GASEOUS fuel (made in the process) is mixed with a regulated supply of air and delivered into a chamber covered by a perforated slab of fireclay, terra-cotta, or other suitable material. Issuing from these perforations it enters into combustion and heats a number of retorts, connected in series, situated overhead. Higher still is a superheating coil, and steam is caused to pass through this previous to entering the retorts in conjunction with liquid hydrocarbon. The retorts are packed with deflecting cones in order to promote decomposition.—A. R. D.

Improvements relating to Artificial Fuel, Refractory Material for Lining Retorts, and Bricks and Tiles. R. Stone, London. Eng. Pat. 13,768, September 24, 1888. 4d.

To form a quickly burning fuel about 3 per cent. of oil of vitriol is mixed with about 97 per cent. of peat, peat litter, or other fibrous carbonaceous material. A small percentage of petroleum or other oil may also be added. For a more enduring fuel, coal is added in any desired proportions. A very refractory material suitable for retort- or converter-linings is prepared by intimately mixing 3 per cent. of vitriol with pulverised slate, slate refuse, or lava. In manufacturing bricks or tiles, the clay is mixed with 3 per cent. of vitriol and the same quantity of petroleum or other oil.

—A. R. D.

Improvements in Coke Ovens. H. H. Leigh, London. From T. von Bauer, Munich, Germany. Eng. Pat. 14,575, October 10, 1888. 1s. 1d.

THESE improvements have reference to the coke ovens described in Eng. Patents 11,010 of 1884, and 6342 of 1887 (this Journal 1885, 486, and 1888, 835). Openings are formed through the side walls of the oven either into the combustion chambers or into the outer air. In the absence of such openings the gases evolved from the oven during any stoppage of the apparatus for recovery of by-products were apt to interfere with the air supply or damage the internal flue structure of the oven. Provision is also made for the more perfect admixture of gas and air in the mixing chambers. The specification is illustrated by five sheets of drawings.—A. R. D.

Improvements relating to the Preparation of Tar, chiefly Designed for Use in the Manufacture of Artificial Fuel. H. H. Lake, London. From F. Homay, Fleurus, Belgium. Eng. Pat. 15,393, October 25, 1888. 6d.

COAL tar and blast-furnace tar are melted and mixed in suitable proportions with or without addition of heavy oils of creosote, the resultant tar being used in manufacture of blocks of artificial fuel.—D. A. S.

Improvements in Apparatus for Automatically Controlling the Generation of Gas from Oil or other Liquid Fuel. C. Brotherhood, Bristol. Eng. Pat. 16,118, November 7, 1888. 8d.

HEREIN is described an apparatus for the automatic control of the process for making gas from oil referred to in Eng. Pat. 1315 of 1888. The upper or moveable part of a gas-holder contains in its lower portion a tank, which is filled with water. The pipe conducting gas from the holder to the burner heating the retort is made to terminate directly over the tank, so that when the upper part of the holder rises, the mouth of the pipe is sealed, and the supply of gas cut off from the burner. As the pressure rises in the holder—and, of course, in the directly connected retort also—it is made to operate in the direction of checking the inflow of oil to be gasified. Four modifications of the apparatus are shown.—A. R. D.

Improvements in and connected with the Manufacture of Illuminating Gas. J. H. R. Dinsmore, Liverpool. Eng. Pat. 16,194, November 8, 1888. 8d.

ACCORDING to these improvements tar or other residual hydrocarbon liquor is introduced into a retort, either mixed with coal or separately therefrom, and the products of distillation, on leaving the retort, are caused to traverse a cooled passage; such cooled passage being preferably a portion of the ascension pipe. If the tar be introduced into the retort by itself, it may be allowed to flow upon a shelf so arranged as to form a kind of horizontal partition in the retort, and over which the gas has to pass on its way to the ascension pipe. The various condensable pitchy matters, which, in ordinary working, are so apt to create trouble by blocking up the apparatus, are arrested in the cooled passage.—A. R. D.

Improvements in Apparatus for use in the Treatment of Gas. J. E. Dowson and A. Dowson, London. Eng. Pat. 16,958, November 24, 1888. 8d.

THIS specification deals with an improved washer and an improved scrubber. The first consists of two or more chambers through which the gas has to pass. The gas inlet and the inter-chamber communications are sealed with water kept at a constant level in the chambers by suitable overflow arrangements. A feature of the apparatus is that the feed-water enters by the pipe which forms the gas exit, and flows thence by means of a suitable partition direct to the chamber where the gas first enters. The scrubber consists of a chamber provided with two or more partitions (formed of perforated gratings) set some distance apart, and having the intervening space filled up with sawdust or other suitable filtering material.—A. R. D.

Improvements in and in connection with Furnaces for Steam Generators and for other purposes. J. Davies, Llanfyllin. Eng. Pat. 316, January 8, 1889. 8d.

IT is proposed to admit a further supply of heated air at some point in the fireflue—preferable the bridge—where the sectional area can be still further diminished by a damper if necessary. The fireflue is also to be fitted internally with a series of fireclay rings decreasing in diameter towards the back, but not to such an extent as to impede the draught. This arrangement is intended to bring the products of combustion into closer contact with the surface to be heated. The furnace is preferably constructed outside the boiler flue, but communicating with it by a restricted passage where the supplementary air supply is admitted as prescribed above.—A. R. D.

Improvements in the Treatment of Coal and small Coke or Breeze in the Manufacture of Gas and Coke. J. Greenfield, London. From C. A. d'Assumpção and E. S. Dias, Lisbon, Portugal. Eng. Pat. 1326, January 24, 1889. 6d.

THE coal to be coked is mixed with a suitable proportion of coke screenings, known as breeze. This is said to increase the brightness and firmness of the coke, and to render it slower of combustion, while a greater quantity of gas of a greater illuminating power is produced per ton of coal.

—A. R. D.

A Method of and Apparatus for Adding Volatile Substances to Gases. S. Fox and E. Blass, Leeds. Eng. Pat. 6130, April 10, 1889. 8d.

THIS method and apparatus is particularly suitable for imparting an odour to water-gas to facilitate the detection of escapes. The apparatus consists of a vessel to which the volatile liquid is supplied from a closed reservoir above, and in which it is maintained at a constant level. This is effected by making the supply pipe from the reservoir terminate at the required height, so that when the liquid in the lower vessel falls below this point, gas makes its way up the supply pipe into the reservoir, and allows a corresponding volume of liquid to descend. A portion of the gas traversing the main is taken by a kind of by-pass through the lower vessel of the apparatus, and, returning to the main, imparts the odour of the volatile liquid to the rest of the gas there.—A. R. D.

New or Improved Regenerating Double Shaft Furnaces with Change of Current. J. von Ehrenwerth, Leoben, Austria. Eng. Pat. 6295, April 12, 1889. 8d.

THIS invention relates to furnaces for heating ingots, tempering or annealing wire, rivets, castings, &c., for smelting metals, burning bricks, and other purposes. The furnaces, which may have either upward or downward inlet flame, have a combination of two furnace shafts, connected together at their ends remote from the inlets by a passage or passages with combustion chambers so that the combustion of the gases may be commenced before entering the shafts. Each shaft communicates through its combustion chamber with a regenerator and arrangements for changing the direction of the current so that the furnaces may be heated alternately, directly and indirectly. The specification is accompanied with two sheets of drawings.

—D. A. S.

Improvements in or Connected with the Manufacture of Water-Gas. J. von Langer and L. Cooper, Leeds. Eng. Pat. 6659, April 18, 1889. 11d.

THIS invention is intended to lessen the cost of manufacturing water-gas by construction of producers and system of working the appliances in groups.

Fig. 1 and Fig. 2 show the producer described. B is the hot blast pipe and *g* the steam entrance. The producer-gas is led off by *c* (Fig. 2), and the water-gas by *h*. The fire-bars are tubular, and are connected with a water service to keep them cool. I (Fig. 1) is an outlet for smoke when neither air blast or steam are on. The sloping hearth facilitates the cleaning of the fire from the doors *a*¹ *a*². The

Fig. 1.

Fig. 2.

producer can be worked with slack and other kinds of soft coal, and may be used as described in Eng. Pat. 8192 of 1889 (this Journal, 1889, 696). In working, after charging and firing, the hot air blast B is turned on (the steam pipe being closed), the producer-gas generated is divided by the double slope of the hearth, and passes downward to outlets $a^1 a^1$. When fuel is highly incandescent the air blast is stopped and steam (which is superheated) admitted, and the water-gas valve h opened. There is a belt pipe a^6 by which the water-gas is led to the scrubber.—D. A. S.

An Improved Method of and Apparatus for Causing complete Combustion of Fuel in Furnaces for Heating Purposes and also Effecting the Abatement of Smoke Nuisance. A. and W. T. Harkness, Sunderland. Eng. Pat. 7044, April 27, 1889. 8d.

Air is conducted from the outside of the furnace or boiler to the combustion chamber by means of pipes or conduits

of iron, fire-brick, fireclay, or other suitable material so that in its passage it may be heated as highly as possible. In most cases it will be best mixed with the furnace gases at the bridge, which may for this purpose be built or made hollow with numerous apertures for the exit of the heated air.—D. A. S.

Improvements in Coke Ovens or Furnaces. A. Weber,
New York, U.S.A. Eng. Pat. 12,092, July 30, 1889. 11d.

BELOW the coking chamber is situated a combustion chamber, wherein the gas made in the process is burned after having been treated for tar, ammonia, &c. The walls of the combustion chamber are channelled to form passages in which this gas and the air necessary for its combustion may be heated before reaching the combustion chamber. The coking chamber is provided with a muffle or mantle, and the products of combustion are caused to pass uniformly round its sides and over the top, finally taking a regenerative part in the heating of the gas and air supply. Full drawings accompany the specification.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS. Etc.

Utilisation of Spent Acid in Petroleum Refineries and Tar Distilleries. C. von Wolniewicz. Chem. Zeit. **13**, 1089.

ALTHOUGH the amount of real sulphuric acid in this by-product is large, nevertheless it is with difficulty recovered, and does not pay for recovery by methods so far put forward. In Galicia the nuisance caused by this acid tar has been felt, and endeavours have been made to remove it. The author proposes to dilute the acid material and then to dissolve in it such metals as iron, zinc, and copper, and use the solution for the impregnation of such materials as wooden railway sleepers. It is stated that the impregnation answers exceedingly well, and especially when carried out hot at about 40° C.

Separation of the Three Xylenes of Coal Tar. A. Renter.
Chem. Zeit. **13**, 830 and 850.

SULPHURIC acid containing over 80 per cent. of H_2SO_4 still acts on meta-xylene, whilst diluted to contain about 84 per cent. its action on para- and ortho-xylene ceases. Ordinary sulphuric acid (93—to 95 per cent.), which was exclusively employed by the author, acts, therefore, on meta-xylene, until in the mixture the ratio of sulphuric acid to water is about 80:20. In para- and ortho-xylene the action will have already ceased when the ratio attains 80:16. This happens, for instance, as soon as 202 grms. of sulphuric acid (93 per cent.) have dissolved 100 grms. of meta-xylene, or as soon as 233 grms. of the same acid have dissolved 100 grms. of para- or ortho-xylene. Hence it follows that to a sulphuric acid saturated with meta-xylene, about one-sixth of its original weight of new acid may be added without the mixture being rendered inoperative for dissolving para- and ortho-xylene.

The crude xylene which the author worked with contained generally more than 60 per cent. of meta-xylene. The treatment with sulphuric acid was carried out in a cast-iron cylinder with a stirring apparatus, or for analytical purposes, in glass flasks with good shaking apparatus. The temperature during the operation rose as high as 80°. Under these conditions the sulphuric acid, if added in sufficient quantity, attacks meta-xylene only. In the selection of the raw material care should be taken to select a product which does not begin to distil under 136°, otherwise the toluene will afterwards render the para- and ortho-xylene impure. Good results were obtained with products that began to distil at 136°, and of which 90 per cent. had passed over at 145°. The raw material should, before separation, be repeatedly washed with small quantities of sulphuric acid (which is to be kept cold) till it becomes not more than slightly brown.

Meta-xylene.—It follows from these remarks that the total amount of meta-xylene can be separated from the raw xylene as sulphonic acid in one operation, by means of sulphuric acid, the quantity of which is determined by a preliminary trial.

The complete removal of the meta-xylene is the object of a subsequent preparation of pure ortho-xylene. One kilo. of washed raw xylene is put into a (graduated) flask, which can be mechanically shaken during several hours, while the quantity of sulphuric acid, sufficient to dissolve 60 per cent. of meta-xylene, calculated as shown above, is gradually added. After allowing it to settle it will not often be found that too little of the substance has been dissolved—that is, that the meta-xylene present was less than 60 per cent. If the solution was normal, a further addition of one-sixth of the sulphuric acid employed will, in most cases, dissolve a few more per cents. If by this the decrease of hydrocarbon is made greater by nearly 60 per cent., the addition of sulphuric acid is, of course, to be repeated. The necessary amount of sulphuric acid roughly estimated in this manner should be controlled by repeating the experiment.

One-third of the quantity of acid thus determined is added to the raw xylene in a suitable stirring apparatus; the remainder and about one-sixth of the acid in excess is added after some time. The influx is to be so regulated that the temperature during the reaction does not exceed 80°. Under these conditions all the meta-xylene passes into solution exclusively as 1, 3, 4 meta-xylenesulphonic acid. After allowing it to settle for some time the acid is drawn off. It still contains 2—3 per cent. of hydrocarbons mechanically dissolved; most of them separate when the acid is diluted. The mixture of acids is, by the addition of water, brought to a specific gravity of 1.4. A considerable rise of the temperature above 100° is of direct advantage, as it prevents a too early crystallisation of the sulphonic acid so that the mechanically dissolved hydrocarbons can separate at the surface. At the same time the greater part of the sulphonic acids of the olefines of the raw xylene, which are present in small quantities, is decomposed. The sulphonic acids of the xylenes begin to decompose only very slightly at 150°.

On cooling slowly the whole mass consolidates to a firm cake of crystals of the *a*-meta-xylenesulphonic acid. The mother-liquor obtained by treating the crystals in a centrifugal machine separates into two layers, a lower one containing nearly pure sulphuric acid of sp. gr. 1.57—1.6, and above it a layer of sulphonic acid for the most part still in a liquid state. From this, repeated crystallisations of *a*-meta-xylenesulphonic acid are obtained after destruction of the olefinesulphonic acid still present by heating, and subsequent addition of sulphuric acid.

If the pure hydrocarbon is to be regenerated from the sulphonic acid, the latter may be decomposed quantitatively with water in a boiler at 220° under pressure. In the case of meta-xylene, a carefully-directed dry distillation of the ammonium salt is also possible, but not in the case of para- and ortho-xylene. The meta-xylene is first acidulated a little with sulphuric acid, and will then give a better yield than by dry distillation of the free acid, without any other secondary decomposition except a partial carbonisation. The yield by distillation of the ammonium salt amounted to 80—90 per cent.

Para-xylene.—The remainder of hydrocarbon separated from the meta-xylenesulphonic acid is, in the same stirring apparatus, at once treated with an excess of sulphuric acid. The elevation of temperature is, if necessary, supported by indirect steam, and is to be kept for some time at 80°; the whole substance, except about 5—10 per cent., will then dissolve. The mixture of acids is drawn off, and again diluted, as in the case of meta-xylene, and left to crystallise in a cool place. The mass at once separates into two layers, of which the lower, containing the sulphuric acid, considerably exceeds in quantity that of the meta-xylene, but also contains no appreciable quantity of dissolved hydrocarbons. The upper layer coagulates to a pulp of needles of the para-xylenesulphonic acid, in the still liquid ortho-xylenesulphonic acid.

The para-compound crystallises completely, and may be obtained so pure, by means of a good centrifugal machine, that the hydrocarbon isolated from it melts at 5°—7°. As

the sulphonic acid is deliquescent, a quick and thorough separation of these crystals is essential for the subsequent preparation of pure ortho-xylene.

Toluenesulphonic acid behaves like para-xylenesulphonic acid, is not easily distinguishable from it externally, and, in the above operation, renders the para-xylenesulphonic acid impure, if the amount of toluene in the raw xylene be considerable.

If a greater purity in the para-xylene be desired, the sulphonic acid, freed from mother-liquor by the centrifugal machine, is to be dissolved in water, and recrystallised by addition of sulphuric acid. The barium salts have not rendered any particularly good service in the separation of the xylenes. For the preparation of absolutely pure para-xylene the beautifully crystallising sodium salt of the sulphonic acid, obtained from the calcium salt, is most preferable.

The only way of isolating the para-xylene is by decomposing it with water in the pressure boiler, where decomposition will take place quantitatively; the sodium salt must previously be acidulated. A dry distillation of the acid, or of the acidulated ammonium salt, is inadmissible, scarcely 20 per cent. of the theoretical produce being obtainable.

Ortho-xylene.—The mother-liquors of the para-xylenesulphonic acid contain, indeed, all the ortho-xylene, but do not, by simple decomposition, produce any hydrocarbon of sufficient purity. It is best to form first the lime salts, and to prepare the sodium salt, which, of ortho-xylene, is particularly easy to obtain in fine crystals, needing not even to be recrystallised in order to furnish, after decomposition, a pure hydrocarbon with a constant boiling point between 143° and 145°. In experimental decompositions the sodium salt behaves like the para-compound. With dilute sulphuric acid or hydrochloric acid the decomposition in the pressure boilers takes place quantitatively. Dry distillation produces even worse results than with para-xylene.

The portion of raw xylene which remained undissolved in sulphuric acid consists of paraffins, and not polymerised terpenes. A hydrocarbon, with its boiling point between those of para- and ortho-xylene, is not present, according to the author's experiments.

After removal of the meta-xylene from larger quantities of the mixture by means of sulphuric acid, the two hydrocarbons might, with advantage, be obtained sufficiently pure for most purposes by fractional distillation with a difference of 7° in the boiling point. The raw sulphonic acids become turbid on the addition of water, not only on account of the separation of the excess of sulphuric acid, but also because, besides a few aromatic hydrocarbons, they contain mechanically dissolved olefines and the like, which separate out on dilution as mentioned under meta-xylene. If the operation were conducted with sulphonic acid only, the mechanical separation from these accompanying bodies is to be effected, if necessary, by dilution or heating, before the preparation of the hydrocarbons can take place. If salts of the sulphonic acids are used, these impurities are not taken into account.

PATENT.

An Improved Construction of Moulds for Casting Rectangular Slabs of Naphthalene or like Material. Fleming's Oil and Chemical Company, Limited, and G. H. Fenner, London. Eng. Pat. 909, January 17, 1889. 6d.

The mould is made in two halves, each having an angular recess. When the two halves are put together, face to face, the recesses form a hollow rectangular prism divided diagonally in the plane of the junction of the two half moulds. Each portion of the mould is made hollow so that it may be kept cool by the circulation of water. The molten material is poured into a kind of elongated funnel, half of which is cast on the top of each half mould.—A. R. D.

IV.—COLOURING MATTERS AND DYES.

The Reactions effected with a Concentrated Aqueous Solution of Formaldehyde. G. Lösekann. Chem. Zeit. 13, 1089—1090.

If a 40 per cent. solution of crude formaldehyde be treated with aniline the latter is dissolved to a clear liquid. After a short time a turbidity arises, and if a large excess of aldehyde were employed, a pasty mass settles to the bottom of the vessel, and is easily soluble in methyl alcohol, and, by evaporation of the solution, furnishes colourless needle-shaped crystals, which are saturated with an oily substance. By taking about equal volumes of aniline and crude formaldehyde, solution is effected; turbidity soon sets in, but then the action seems to cease. If heat be now applied, the reaction proceeds very vigorously, and a portion of the excess of aldehyde is volatilised. As a residue there remains a hard sponge-like mass, which, triturated in a mortar and washed with water, is not so soluble in methyl alcohol as the preceding substance. After washing with alcohol, a quantity of small white needles remain, which appear to be identical with the crystals first obtained. This crystalline substance was found to be identical with the anhydroformaldehyde-aniline obtained by Wellington and Tollens (Ber. 1885, 18, 3309). Similar products were obtained from *o*-toluidine and *p*-toluidine.

Benzamide, warmed with a concentrated solution of crude formaldehyde, undergoes solution; but the expected separation of the product of the reaction did not take place. The solution evaporated on the water-bath remains liquid for some time, and then all at once solidifies to a hard colourless cake of crystals. The crude product melted at 203°, after washing with alcohol, at 212°, after once recrystallising from alcohol, at 216°, and after twice recrystallising, at 218° C.

If a solution of magenta be treated with crude aldehyde, the colour becomes much more intense and acquires a violet shade. Probably the action has taken place in such wise that the aldehyde has reacted upon an amido-group, for the colour will be observed to have taken a shade of violet, a peculiarity also perceived when the hydrogen atoms of an ammonia group are replaced by hydrocarbons. If now some free hydroxymethyl sulphonic acid be added, the colour becomes still more intense. When added directly to magenta solutions, in presence of the hydroxymethyl sulphonic acid, soluble and insoluble violet-red compounds are produced of much greater intensity of colour than is possessed by magenta. Rosaniline, prepared from commercial magenta, was next treated with aldehyde. The base was dissolved with a violet-red colour. The whole was now evaporated on the water-bath to dryness. A residue was obtained, which was at first coloured like the solution, but afterwards became greyish-yellow. Treated with a little hydrochloric acid, a violet-red coloured solution was again formed, which, with more acid, like magenta, was decolourised. This proves that there was present a substituted rosaniline. If the latter be heated with an aqueous solution of hydroxymethyl sulphonic acid, an intensely coloured violet dyestuff is produced. It thus appears that the hydroxymethyl sulphonic acid effects a still further substitution.

The hydroxymethyl sulphonic acid can either be used in the free state or in the form of its alkaline or barium salts.

On the Difference of Action of Sulphuric and Selenic Acid in Organic Chemistry. M. Istrati. Bull. Soc. Chim. [3], 1, 480—481.

SULPHURIC acid acts on benzene, producing sulphonic acid, a sulphonic and francine. ("Francine": Peculiar colouring matters formed together with sulphonic acids by the action of sulphuric acid on the higher chlorinated benzenes. Bull. Soc. Chim. 48, 35; Compt. Rend. 106, 277; J. Chem. Soc. 1888, 259 and 591.) In the formation of this latter product probably an oxidation takes place, and the author tried the action of other acids containing oxygen and benzene to see whether a similar reaction took place. The experiments with phosphoric acid and selenic acid were

without result; in the case of the latter, only a small quantity of crystals of what was probably barium benzeneselenate being obtained. Acting on pentachlorobenzene with selenic acid a selenate was formed, but no selenobenzene, nor the corresponding "francine."—A. L.

On the Transformation of Sulphonic Derivatives under the Influence of Heat in Presence of Sulphuric Acid. M. Istrati. Bull. Soc. Chim. [3], 1, 492—496.

THE author describes some experiments made on benzene and chlorobenzene with sulphuric acid. If 200 cc. of benzene be treated with 300 cc. of concentrated sulphuric acid at 80° C. for 3—4 days, the benzene is converted into its monosulphonic acid. If now the temperature is raised to 100° C. part of the sulphonic acid is reconverted into benzene, water and sulphurous acid being formed at the same time. When all benzene has been removed by distillation the temperature rises to 150° C., the sulphuric acid becomes black, and a crystalline body, sulphobenzide, sublimes into the neck of the flask. The author explains these reactions by the following equations:—

or more probably

If the calcium salt of trichlorobenzenesulphonic acid be boiled with two parts of sulphuric acid, sulphurous acid, water, hydrochloric acid, and an oily liquid trichlorobenzene are formed, besides, probably, the calcium salt of dichlorobenzenesulphonic acid. By the following equations it is sought to explain these reactions:—

—A. L.

On Diphenoltrichlorethane and p-Dihydroxystilbene. K. Elbs and O. Hoermann. J. Prakt. Chem. 1889, 39, 498—502.

DIPHENOLTRICHLORETHANE, like diphenyltrichlorethane, yields, on treatment with zinc dust and alcohol, a stilbene derivative, *p*-dihydroxystilbene. To prove its constitution, the product was acetylated and oxidised in acetic acid solution by potassium permanganate. *p*-hydroxybenzoic acid was thus formed. A further proof was forwarded by converting *p*-diamidostilbene, through the diazo-compound, into the dihydroxy-compound, which corresponded in its properties exactly with the compound prepared by the authors. It combines with diazo-compounds, and forms dyes. Ammonia does not change the phenol into an amide at 230° C. Addition of three parts of nitric acid (sp. gr. 1.52) to one part of the diphenoltrichlorethane dissolved in five parts of glacial acetic acid, produces dinitro-*p*-dihydroxydiphenyltrichlorethane, melting at 159° C., little soluble in glacial acetic acid, xylene, and alcohol, easily in nitrobenzene and acetone. It explodes when heated above its melting point. Its diacetyl-compound forms light yellow plates, melting at 197° C. On further nitration with nitric and sulphuric acid, a tetranitro-compound is formed, crystallising in needles melting at 252° C. The dinitro-compound yields, on reduction, a diamido-compound crystallising from alcohol in colourless needles, turning black at 95° C., and decomposing without melting at a higher temperature. The authors give, further, an easy method of preparation for *p*-diamidostilbene. 10 grms. of dinitrostilbene are heated on the water-bath with 100 cc. of alcohol. The calculated amount of hydrochloric acid (sp. gr. 1.18—1.19) and the calculated amount of tin are then added. After boiling for 2—3 hours, the same quantity of tin and hydrochloric acid as before are added, and the boiling is continued for about 1½ hours, the

flask being well shaken until the solution appears light brown. After filtration and evaporation of the alcohol, the filtrate is poured into an excess of caustic soda, which must not be too dilute. The precipitate of diamidostilbene settles easily, and the liquid is removed by decantation. After washing with dilute caustic soda, it is filtered, washed with water, and recrystallised.—A. L.

On the Oxidation of Triphenylmethane. M. Harriot and O. Saint-Pierre. Bull. Soc. Chim. [3], 1, 773—774.

The authors suspected a specimen of triphenylmethane, prepared by the action of chloroform on benzene in presence of aluminium chloride, to contain a homologue due to the presence of toluene in the benzene. To decide this question the body was oxidised. 50 grms. of it were boiled for 15 hours with 500 grms. of potassium bichromate and 2 kilos. of a mixture of one part of sulphuric acid and one part of water. The excess of bichromate is then destroyed by alcohol and the mixture filtered through glass wool after cooling. The filtrate and the residue were shaken with ether. The latter yielded to caustic potash the acid products which were on acidulation with sulphuric acid precipitated. Steam was passed through to remove benzoic acid and the remaining product crystallised from water and alcohol. It melts at 87° C., becomes then again solid, and remelts at 125° C. It was proved to be *o*-benzoylbenzoic acid. The ethereal solution contained also benzophenone and triphenylcarbinol, melting at 159° C. The sulphuric acid solution of chrome alum was observed to contain anthraquinone, which originated probably from benzoylbenzoic acid. The latter, however, could not have been produced unless there had been a side chain in the hydrocarbon.—A. L.

The Action of Potassium on Triphenylmethane. M. Harriot and O. Saint-Pierre. Bull. Soc. Chim. [3], 1, 774—780.

TRIPHENYLMETHANE is not acted upon by sodium. If, however, it is heated with potassium to 200° C., hydrogen escapes, and the metal enters into combination with the hydrocarbon. When carbonic acid is passed over this new compound, triphenyl acetic acid is formed identical with the one obtained by Fischer. Benzylchloride forms benzyltriphenylmethane ether, $C_6H_5CH_2C(C_6H_5)_3$, or—

By the action of benzoylchloride on the metal compound benzoylphenylene, diphenylmethane is formed.

If the compound of potassium and the hydrocarbon be heated to 250° C., again hydrogen is evolved, and a new compound, is formed, $C_{19}H_{11}$, boiling above 360° C. and melting at 148.5° C., identical with a body obtained by Hemilian. Its constitution, according to the authors' view, is $C_6H_4:C(C_6H_5)_2$.

Potassium acts also on tetraphenylethylene, and the product, when treated with benzylchloride, forms a hydrocarbon, melting at 237° C., which has to be considered as a benzyl-derivative of tetraphenylethylene. Some bromo- and nitro-derivatives of the above-described compounds are mentioned.—A. L.

Action of Dimethylaniline in Presence of Aluminium Chloride. H. Giraud. Bull. Soc. Chim. [3], 1, 691—693.

ALUMINIUM chloride combines with dimethylaniline with evolution of great heat. The product of the reaction crystallises in long prisms, melting at 88° C., but decomposing rapidly, so that its composition could not be exactly determined. If dimethylaniline be heated with five parts of aluminium chloride in a sealed tube, no reaction takes place. Air having access, a product is formed, which is obtained pure by adding an excess of caustic soda to dissolve the aluminium hydrate, and removing the dimethylaniline by distillation with steam. A solid base—

remains, crystallising in small needles melting at 195° C. By the action of gaseous hydrochloric acid, the base forms

at 180° C. benzidine and methyl chloride. The reaction between dimethylaniline and aluminium chloride is due to oxidation by the air. If a mixture of ferric and aluminium chloride be used and air excluded, the ferric chloride is reduced, but only red substances are obtained, which were not examined. When, however, pure aluminium chloride and dry oxygen were applied, a considerable quantity of methylbenzidine was formed. By acting on dimethylaniline containing dimethyltoluidine, a new base, tetramethyldiamidodiphenylmethane, was obtained, melting at 90° C.

—A. L.

PATENTS.

The Manufacture of the Sulpho Acids of a Red Basic Naphthalene Dyestuff. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 15,259, October 23, 1888. 8d.

WHEN naphthoquinone dianilide is heated with aniline and its hydrochloride a red basic colouring matter is obtained to which the name *Rosinduline* has been given (Chem. Soc. J. (Trans.) 1888, 1291). This, by the action of sulphuric acid, is converted into sulphonic acids, which can be used for dyeing and printing. Naphthoquinone dianilide is produced by the action of aniline on derivatives of α - and β -naphthoquinone and upon nitroso- and azo-naphthalene derivatives. By heating the last-named compounds with aniline and its hydrochloride, the formation of naphthoquinone dianilide and its conversion into the red colouring matter can be effected in one operation. The following compounds yield naphthoquinone dianilide:—Amidonaphthoquinonimide, β -naphthoquinone and its anilide, benzolazo- α -naphthylamine, benzolazo-ethyl- α -naphthylamine, benzolazo- α -phenyl-naphthylamine, benzolazo- α -naphthol, nitrosophenyl- α -naphthylamine, nitroso- α -naphthol, nitroso- β -naphthol and dibromo- α -naphthol. The following compounds also yield rosinduline when heated with aniline and its hydrochloride: α -naphthoquinone, chloro- α -naphthoquinone (m.p. 111°), hydroxy- α -naphthoquinone, α -naphthoquinone anilide and benzene-azodimethyl- α -naphthylamine. The following are the details of the invention:—10 kilos. of benzolazo- α -naphthylamine hydrochloride are mixed with 10 kilos. of aniline hydrochloride and 35 kilos. of aniline in an enamelled vessel. The melt is continually agitated and the temperature is raised in about 4 hours to 130°. It is then gradually raised in another 4 hours to 170°, and this temperature is maintained for 4 hours longer or until a sample dissolved in sulphuric acid shows a pure green colour. The melt after cooling is boiled with dilute hydrochloric acid, and the residue purified by heating 10 kilos. of it with 30 kilos. of toluene to 100° which dissolves out the impurities. The undissolved residue is dissolved in about 20 kilos. of hot alcohol, filtered, and caustic soda added to the filtrate until alkaline, when the base separates out. It crystallises from toluene in dark reddish-brown crystals, melting at 234°. By the action of sulphuric acid sulphonic acids of this substance are produced, containing one or more sulphonic groups according to the concentration of the acid and the temperature at which the sulphonation is effected.

Monosulphonic Acid.—10 kilos. of the compound, or of its hydrochloride or sulphate, are mixed with 50 kilos. of sulphuric acid containing 96 per cent. of H_2SO_4 and heated to about 100° for 5 hours, or until a sample after precipitation with water dissolves to a clear solution in caustic soda. The melt is then poured into 10 times its weight of water, and if necessary purified by conversion into the sodium salt, which is afterwards decomposed by dilute sulphuric acid.

Disulphonic Acid.—10 kilos. of rosinduline or of the monosulphonic acid just described, are mixed with 30 kilos. of sulphuric acid containing 23 per cent. of SO_3 and heated to 40° until a sample when diluted with water gives a red precipitate which is perfectly soluble in pure boiling water. The melt is then poured into 200 litres of water at 0°, and the precipitate after filter-pressing is suspended in 400 litres of water, and caustic ammonia added until it dissolves. The ammonium salt crystallises out on evaporation.

Soluble Sulphonic Acid.—The monosulphonic acid above mentioned is heated with six times its weight of

sulphuric acid containing 23 per cent. of SO_3 to 100° , until a sample is easily soluble in 20 parts of cold water. The melt is then diluted with about 10 times its weight of water, limed, filtered, and the solution decomposed with sodium carbonate to obtain the sodium salt. Either of the two last mentioned acids dye animal fibres crimson from an acid bath, and are recommended as substitutes for archil.

—T. A. L.

Improvements in the Preparation of a Beta-Naphthylamine Sulphonic Acid and of Colouring Matters therefrom. A. G. Green, London. Eng. Pat. 15,849, November 2, 1888. 4d.

THIS patent describes a new method for the production of the acid commonly known as the δ -sulphonic acid of β -naphthylamine.

Equal molecular proportions of β -naphthol and sulphuric acid containing 100 per cent. of H_2SO_4 are heated to 100° — 130° until the sulphonation is complete. The melt is dissolved in water, salt added until all tar is precipitated, and the solution is filtered, when the sodium salt of the acid separates out on cooling. It is converted into β -naphthylamine sulphonic acid or a salt thereof by heating dry in a current of ammonia gas or in an autoclave with caustic ammonia or with a salt of ammonia and an alkali. The product is dissolved in water, precipitated by an acid, and the β -naphthylamine- δ -sulphonic acid is separated from the β -naphthylamine- β -sulphonic acid which is formed simultaneously, by well-known methods. By decomposing the former with sodium carbonate the sodium salt is obtained which can be employed directly for the production of colouring matters either by acting on it with diazo-compounds, such as diazobenzene, diazotoluene, diazonaphthalene, tetrazodiphenyl, tetrazostilbene, &c., and their sulphonic acids, or by diazotising the β -naphthylamine sulphonic acid described and combining it with amines and phenols or their sulphonic acids.—T. A. L.

Manufacture of Induline Colouring Matters Soluble in Water. O. Imray, London. From "The Farbwerke vormals Meister, Lucius and Brüning," Höchst, Germany. Eng. Pat. 16,325, November 10, 1888. 4d.

COLOURING matters of the induline series soluble in water are obtained by heating induline with *p*- or *m*-diamines to 150° — 190° . 10 parts of induline, 15 parts of *p*-phenylenediamine, and 2 parts of benzoic acid are heated to 150° — 180° until a sample dissolves to a clear solution in dilute hydrochloric acid. The melt is then dissolved in dilute hydrochloric acid, filtered, and the dyestuff precipitated with salt. The colouring matter so formed dyes a greenish-blue shade, whereas if 12 parts of *m*-phenylenediamine be employed in place of the *p*-diamine a reddish-blue is produced.—T. A. L.

Improvements in the Production of Colouring Matters resembling the Indulines. C. D. Abel, London. From "The Farbwerke vormals Meister, Lucius and Brüning," Höchst, Germany. Eng. Pat. 16,393, November 12, 1888. 6d.

AMIDAZOBENZENE hydrochloride, when heated with secondary or tertiary aromatic amines, such as mono- or dimethyl- or ethyl-aniline, to about 150° , forms colouring matters soluble in water. 15 kilos. of amidazobenzene hydrochloride and 20 kilos. of dimethylaniline are slowly heated to 150° in an enamelled vessel under constant agitation. Between 110° and 130° a reaction sets in, and care must be taken that the temperature does not rise above 150° . The melt becomes ultimately bluish-violet, and when no further reaction takes place at 150° it is mixed with dilute hydrochloric acid (1:3) until all the dimethylaniline in excess is dissolved. Salt and zinc chloride are then added and the colouring matter filtered off. It is used preferably in the form of a paste, as it becomes somewhat less soluble in water on drying. It dyes cotton a bluish-violet shade.

—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENT.

Improvements in or applicable to the Treatment of Esparto Grass for obtaining Fibre therefrom. J. Mactear, London. Eng. Pat. 16,943, November 21, 1888. 4d.

THE improvements consist in a preliminary mechanical disintegration and partial separation of the silicious coating of esparto grass by piercing it with a number of fine pins fixed to a plate driven rapidly with a reciprocating motion. In this way the subsequent process of boiling with soda is performed in less time and with a saving of chemical.

—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

On the Power of Resistance of Dyed Fibres to the Action of Light. J. Joffre. Bull. Soc. Chim. [3], 1, 553—555.

CHEVREUL has shown that if coloured materials be submitted to the action of light in vacuo, in most cases no decolourisation takes place. The author has made some experiments in the same direction, submitting the dyed fibres to the action of sunlight instead of to an atmosphere of nitrogen in vacuo. He operated in glass tubes, removing the oxygen by pyrogallie acid and potassium hydrate. A great number of colouring matters remained unchanged. The results with cyanine were most striking; this colouring matter did not suffer at all under the conditions named. The shades obtained with picric acid, however, turned orange. The same results were produced when the dyed fibre was surrounded by a layer of transparent paraffin. Albumen and gelatin also offered very efficient protection.

—A. L.

PATENTS.

Improvements in Apparatus for Treating Cloth, Yarn, and other Materials. F. Moore, Trowbridge. Eng. Pat. 15,103, October 20, 1888. 8d.

THE material to be dyed is hung on a frame which is made to rotate in a cylinder containing the dye; or the cylinder itself may be made to rotate.—E. J. B.

Improvements in the Method of and Apparatus for Dyeing Woollen Cloths and other Fabrics. J. H. Hepworth, Churwell. Eng. Pat. 15,955, November 5, 1888. 6d.

THE inventor claims the use of a perforated partition, which prevents the material to be dyed from coming in contact with the steam pipe used for heating the dye-bath.—E. J. B.

A New or Improved Dyeing Material, and Method of Employing the Same. C. F. Z. Noroy, Paris, France. Eng. Pat. 17,094, November 24, 1888. 6d.

THIS invention relates to the preparation and use of a new material applicable to the dyeing of animal and vegetable fibres and skins of all kinds. It is produced by the action of nitric acid upon "fecula, starch, or flour, or more generally upon lignine and cellulose," being the product which is formed between the first and last stages of oxidation of these materials by nitric acid. Its usefulness depends upon its property of dissolving almost all known metallic and earthy oxides (such as are used as mordants), and of preventing their reprecipitation by excess of alkalis. For its preparation, two parts of nitric acid are added to one part of starch, and the mixture heated slightly in an enamelled vessel. As soon as the reaction is fairly established, the vessel is removed from the source of heat, and the action allowed to complete itself. The resulting liquid is termed "nitrated or denatured starch." Its use is illustrated in the following recipe for dyeing black:—

1st Bath.—30–40 parts of dry extract of logwood; 1,000 parts of warm water. Dissolve, cool, and add a mixture of 6–10 parts of sulphate, nitrate, acetate, or other salt of copper; 20–30 parts of water; 5–7 parts of hydrochloric acid; 10–15 parts of acetic acid.

This bath may be modified by addition of tannic extracts, rosewood, turmeric, coal-tar dyes, &c.

2nd Bath.—130 parts of “nitrated starch”; 21 parts of sulphate of copper (or its equivalent of oxide); 40 parts of sulphate of alumina (or its equivalent of hydrate); 12 parts of arsenious acid dissolved in a solution of 6 parts of potash; sufficient ammonia added to make the mixture neutral; then 1,000 parts of water; and, finally, 5 parts of carbonate of soda.

Modified baths are described, containing sulphate of iron, chloride of antimony, sulphate of magnesia, protochloride of tin, &c.

In performing the dyeing process, the material operated upon is immersed in bath No. 1 for one or two hours, wrung, and partly dried in the open air or in a stove; it is then immersed in bath No. 3 for from three-quarters of an hour to an hour and a half, care being taken that the bath is kept alkaline. The material is wrung out lightly and exposed to the air for from one to three hours, until the black is completely developed, well washed, and dried. These dyeing operations are conducted in the cold, except with materials difficult of penetration, in which latter case the baths may be heated to 40°–60° C.; but the second bath must only be heated towards the end of the operation.

—W. E. K.

Improvements in Apparatus for Washing, Soaping, Scouring, Bleaching, Dyeing, and otherwise similarly Treating Textile Fabrics. 1. Pollard, Hyde. Eng. Pat. 18,987, December 29, 1888. 6d.

The inventor claims an improved roller made up of a number of blades or scoops fixed on a skeleton roller, and caused to revolve in a tank containing the necessary liquid. The shape of the roller causes the fabric to be beaten, and at the same time subjected to the action of liquid caught up by the scoops.—E. J. B.

VII.—ACIDS, ALKALIS, AND SALTS.

On the Utilisation of the Heat of Pyrites-Burner Gases. G. Lunge. Zeits. f. angew. Chem. 1889, 297–299.

It is not very long since the gases from pyrites-burners were deprived of their superabundant heat before entering the sulphuric acid chambers by being cooled, in long conduits, with air or water, and without making any use of this heat. At present, as is well known, this heat is either utilised in concentrating sulphuric acid in evaporating pans placed over the gas flue, or, in a still more direct way, in concentrating chamber acid in the Glover tower, or by the adoption of both these plans. As shown by the author some years ago, the denitrating action in the Glover tower takes place almost completely in the upper part of the tower, whilst in the lower part the acid is concentrated, and this concentration is effected entirely at the expense of the heat of the burner-gases. To a certain extent, at least, it is perfectly practicable to carry on this concentration of chamber acid by means of the heat of the burner-gases outside of the Glover tower—their heat can be first utilised in

Fig. 1.

Fig. 2.

Fig. 3.

concentrating chamber acid by an indirect system of heating in pans, or by lead piping, &c., and the partially-cooled gases can then be lead into the Glover tower, where, in this condition, they will naturally effect merely a denitrating action. By adopting such an arrangement, there is a decided gain when acid is manufactured for sale or when it is to be concentrated to 66° B. (sp. gr. 1.842), as the acid can then be obtained free from the iron and alumina which are otherwise unavoidably derived from the Glover tower. At the same time the author states, in a footnote, that the temperature of the gases must not be lowered beyond a certain limit, and in a future communication he will show that the working of the Glover tower requires a certain moderately high temperature.

Figs. 4 and 5.

The advantage to be gained by the above method is not so great when the acid is made for use in the manufacture of sulphate of soda or superphosphate. There may be cases, however, in which, owing to lack of space, the Glover tower has been placed too near the burners, so that it is damaged by the high temperature of the burner-gases.

Such a case occurred, among others, in the large manure works of Messrs. H. and E. Albert, in Biebrich, where the Glover towers are only 1.5 metres distant from the burners, and the hot gases made the stones at the inlets red hot, and destroyed the towers and their stone packing. These objectionable features have been avoided by first utilising the excess heat of the gases for warming air, which is afterwards used for drying purposes. The firm of Messrs. Fellner and Ziegler of Bockenheim erected the plant, drawings of which are given in Figs. 1—5. Figs. 1—3 represent a horizontal system of cooling pipes; Fig. 1 is the ground plan; Fig. 2, a longitudinal section; and Fig. 3, a cross section.

On each of the burners, A, is built a gas chamber, B, whose length is two-thirds that of the burner. The burner-gases enter these chambers through valvular openings, a, and pass through similar openings, b, into the pipes, d, leading to the Glover towers, C; a third opening, c, permits the gases, if desired, to pass direct into d and C. In each of the chambers, B, lie horizontal cast-iron pipes, e, which form branches of a main pipe, f, through which cold air is forced by means of a blower, g. This air is thus exposed to the heat of the burner-gases in the chambers, B, becomes itself heated, and leaves the chambers through branch pipes leading into the main, h. The latter is protected by non-conducting material, and opens into the flue, i, whence the drying apparatus, D, can be supplied with heated air. In these works the air is heated to a temperature of 100° C., but, by regulating the speed of the blower, the temperature can be reduced or increased (up to 135° C.). The burner-gases, which enter the Glover towers, C, through d, are still hot enough to carry out all the usual concentrating and denitrating operations. But the acid, which formerly ran off at a temperature of 140°, is now reduced to from 115° to 120°, and, therefore, requires less cooling for use in the Gay-Lussac tower, and the durability of the Glover towers is increased. At the same time an economy of fuel has been effected in the drying process, amounting to 5,000 kilos. of coal daily, and the character of the manufactured product

is much improved by the use of pure air for drying, instead of the smoke gases formerly used.

Figs. 4 and 5 show an upright system of cooling pipes, and need no further explanation. This system is, nevertheless, not so much to be recommended as the horizontal one, in which the direction of the draught is unaltered, and there is no irregularity in the working.—H. S. P.

On the Recovery of Sulphocyanogen and Ferrocyanogen from the Spent Oxide of Gas Purifiers. J. V. Esop. Zeits. f. angew. Chem. 1889, 305—307.

THE sulphocyanates in spent oxides are soluble in water and alkalis, whilst the ferrocyanogen, which exists in the form of a double compound of Prussian blue and ammonium-ferrocyanide, is insoluble in water but soluble in alkalis. Besides the cyanogen compounds the spent oxide also contains ammonium and sodium sulphates, small quantities of sulphites and sulphides, and a considerable quantity of sulphur associated with tar.

Below are given the percentages of sulphocyanic acid, ammonia, and potassium ferrocyanide obtainable from various samples of spent oxide:—

Spent Oxide from	HCNS.	NH ₃ .	K ₄ FeCy ₆ +3 aq.
Stuttgart	0·85	1·03	3·54
Leipzig	1·62	2·06	4·42
—	1·98	2·31	4·51
Ulm	1·05	1·42	5·43
Pforzheim	2·32	2·43	4·37
Heilbronn	3·53	3·21	4·84
Nürnberg	3·72	1·24	4·53
Zürich	4·07	1·64	3·87
Mainz I.	3·87	2·23	4·07
Mainz II.	4·25	2·26	4·38
Wiesbaden	1·12	0·23	8·27
Remscheid	4·06	2·42	9·03

It happens sometimes that spent oxides cannot be conveniently worked up just after using, and have to be stored. When this is the case great care should be taken in storing to prevent heating, which easily takes place in the presence of so much sulphur (30—40 per cent.); on heating the sulphocyanate decomposes, a portion being converted into ammonium sulphite and sulphate, and another portion into ferrocyanide. This "heated" spent oxide is more difficult to treat, and the cyanogen compounds cannot so readily be extracted.

The author has tried several mechanical methods of lixiviating the spent oxide without obtaining entirely satisfactory results; viz., washing in Shank's lixiviators (as used in the Leblanc soda process); also a method of mechanical stirring, first with water to extract the sulphocyanates, and next with alkaline solutions (of caustic soda or caustic lime) to remove the ferrocyanides and expel ammonia; and a process patented by Kunheim and Co. (Jahresb. 1884, 470), consisting in grinding the oxides, exhausting with water, then heating with quicklime in closed vessels to liberate ammonia, and again lixiviating with water to remove the ferrocyanide. He finally arrived at a convenient and cheap method of extraction by treating the spent oxide with lime and sulphate of soda at a certain temperature. The solvent action on the double salt of Prussian blue and ammonia is explained as follows:—The lime liberates a portion of the ammonia, and this brings about the double decompositions of the caustic lime and sodium sulphate forming caustic soda and calcium sulphate, a reaction which under ordinary conditions does not take place:—

About as much sodium sulphate is required as there is potassium ferrocyanide obtainable from the spent oxides. By this method the sulphocyanates and ferrocyanides are obtained in the same liquor, and are afterwards separated by fractional precipitation and worked up into sulphocyanates and Prussian blue. As a result of many extractions the author found that more sulphocyanate was obtained by this alkaline process of extraction than when the spent oxide was treated with water only, leading to the conclusion that a sulphocyanogen compound insoluble in water occurs in the spent oxide. Some of the results are shown below:—

Spent Oxide from	HCNS dissolved in	
	Water.	Alkali.
Mainz	3·56	5·98
Zürich	2·56	2·85
Hanau	3·72	4·40
Pforzheim	3·56	5·98

The process of lixiviation is carried on in an upright wrought-iron boiler, provided with a stirring apparatus. Steam is led into the mixture and the air exhausted by a pump. The required temperature is soon reached and the ammonia evolved is drawn off by the pump and forced into acid. A cooling apparatus between the pump and the boiler condenses the steam. After some hours the material is exhausted and the whole driven over into a settling tank. The clear liquor, containing the sulphocyanates and ferrocyanides, is drawn off, whilst the residue is pressed or filtered to obtain the adhering liquid.—H. S. P.

The Formation of Hydrogen Peroxide from Sulphur Peroxide. M. Traube. Ber. 22, 1518—1528.

THE sulphur peroxide compound is prepared by electrolysis of 40 per cent. sulphuric acid solution. This is made up to 70 per cent., brought into a flask with inlet and outlet tubes and tap funnel, and cooled to -12° . Oxalic acid is now run in and the air drawn through baryta water. No carbon dioxide was evolved.

The amount of hydrogen peroxide and SO_4 present were then determined in the same sample. The results obtained were as follows:—

The oxalic acid is unacted upon by SO_4 in presence of 70 per cent. sulphuric acid. In the first hour about two-thirds of the SO_4 had decomposed, the available oxygen combining to form H_2O_2 , without interruption from the presence of oxalic acid. If the action of SO_4 in presence of oxalic acid lasts 2—3 hours a secondary reaction begins with evolution of CO_2 , but this the author finds is due to the oxidising action of H_2O_2 .

SO_4 is indifferent towards carbonic oxide. It has, therefore, a weak oxidising action. The statement of Richarz that H_2O_2 is only formed in presence of 70 per cent. sulphuric acid is not confirmed by the author, who finds that 40 per cent. acid acts equally well.

The apparent anomaly that hydrogen peroxide is produced by a weak oxidising agent is readily explained because the former body cannot exist in presence of a strong oxidiser, becoming rapidly oxidised to water.

SO_4 and H_2O_2 react slowly on one another. Sulphur peroxide has a slow and often scarcely perceptible action on organic bodies. Indigo sulphonic acid is slowly decolourised. The peroxide in neutral solution is reduced by alcohol after several days. As_2O_3 is also oxidised.

The author considers the peroxide to belong to the type of hydrogen peroxide from its characteristic chemical properties, which accord with those of the hydrogen compound. The compound has therefore the formula $\text{SO}_2(\text{O}_2)$.

On this assumption the various reactions are readily explained.

Hydrogen peroxide with sulphuric acid gives sulphur peroxide.

That hydrogen peroxide is not formed by oxidation of water is shown by bringing barium peroxide into hydrochloric acid. If any free oxygen were formed, chlorine would be evolved, but this is not the case. The author concludes his paper by discussing the formula of hydrogen peroxide, which he regards as a compound of hydrogen with molecular oxygen $H_2(O_2)$, and not, as usually considered, the result of the union of two hydroxyl groups.

—J. B. C.

The Action of Acids and of Metallic Salts on Sodium Thiosulphate. G. Vortmann. Ber. **22**, 2307—2312.

The author differs from the opinion expressed by Vanbel as to the action of acids on sodium thiosulphate (see this Journal, 1889, 704), according to which $H_2S_2O_3 = H_2S + SO_3$, and points out that owing to the long time (two hours) during which the experiments were carried on, secondary decompositions would be likely to occur, and also that the use of strong acids, especially of sulphuric acid, would also have a similar tendency.

In the experiments described, an aqueous solution of sodium thiosulphate is treated in a small flask with dilute acid or with a solution of a metallic salt, the mixture heated to boiling, to drive out the sulphur dioxide, and the other products of decomposition determined in the residue. The removal of the sulphur dioxide is promoted by passing a current of hydrogen or of carbon dioxide through the apparatus during the experiment; this also prevents oxidation to sulphuric acid, by the oxygen of the air, taking place. The primary decomposition is, according to the author—

whilst the nature of the final decomposition products depends upon various circumstances. Either the oxygen acts on the sulphuretted hydrogen with separation of sulphur and formation of sulphur dioxide, or sulphuretted hydrogen is liberated and the sulphur dioxide oxidised to sulphuric acid, or finally the oxygen acts upon undecomposed thiosulphate with the formation of sodium tetrathionate. On boiling pure sodium thiosulphate with dilute hydrochloric acid the following decomposition takes place:—

At the same time, up to 20 per cent. of the thiosulphate is converted into sodium tetrathionate, and a little pentathionate is also formed. Quantitative experiments show that the amount of free sulphur actually obtained corresponds very closely to that required by the above equation. In no instance was the formation of sulphuric acid noted, and the author states that traces of this acid present as impurity in the thiosulphate are liable to be overlooked in testing with barium chloride, and recommends titrating with decinormal iodine until the solution is just yellow, and then acidifying with hydrochloric acid before testing with barium chloride. The decomposition by hydrochloric acid is the same whether an excess of acid or of thiosulphate is present; certain salts of the alkali and alkaline earths modify the reaction slightly—potassium iodide, for example, increases the amount of sulphur separated and gives rise to the formation of a little sulphuric acid.

A neutral solution of aluminium chloride decomposes sodium thiosulphate as hydrochloric acid does. At the start a little hydrogen sulphide is evolved, then aluminium hydrate mixed with sulphur is separated; 3.25—4.25 per cent. of the thiosulphate is converted into tetrathionate, but no trace of sulphuric acid results except when potassium iodide is added, as in the case of hydrochloric acid. Sodium thiosulphate heated with copper sulphate is decomposed with the liberation of sulphuric acid, a fact which the author is taking advantage of for establishing an acidimetric method for the determination of copper. Mercury salts decompose sodium thiosulphate with formation of sulphide, the filtrate from which contains much sulphuric acid, little tetra- and no pentathionic acid. With arsenious and arsenic acids, also with antimony chloride, the corresponding sulphide is precipitated, and only a trace of sulphuric

acid results. Tetrathionic acid is formed in the case of arsenious acid and of antimony chloride; with arsenic acid pentathionic acid is obtained. Stannous and stannic chloride act similarly on sodium thiosulphate. A precipitate consisting of mixed sulphide and hydrate is obtained, while the filtrate contains sulphuric and pentathionic acids. From these experiments it appears that when sodium thiosulphate is decomposed in absence of a metal forming an insoluble sulphide, the sulphur dioxide liberated acts upon the hydrogen sulphide with the separation of sulphur. In presence of metals whose sulphides are not soluble, or only slightly soluble in dilute acids, the oxygen set free in the decomposition either oxidises the sulphur dioxide to sulphuric acid or converts unchanged sodium thiosulphate into tetra- or pentathionate.—C. A. K.

Researches on the Sulphites. P. J. Hartog. Compt. Rend. **109**, 179—182; 221—223; 436—439.

Potassium Sulphite, K_2SO_3 , is obtained by dissolving 100 grms. of pure potash in 200 grms. of water in a current of nitrogen, and then saturating the solution with sulphur dioxide. 100 grms. of potash dissolved in the least amount of water are then added. The flask is exhausted and heated in an oil-bath. The crystals formed are filtered off through wadding in a current of nitrogen, pressed rapidly between filter paper and dried in a vacuum. The salt crystallises in hexagonal prisms; these are deliquescent, and oxidise in the air. Cold is produced by their solution in water.

Sodium Sulphite, Na_2SO_3 , is prepared in exactly the same way as the potassium salt, though it is always impure, containing crystals of the hydrated sulphite $Na_2SO_3 \cdot 7 H_2O$. The crystals are sometimes 2—3 mm. in length, and crystallise as hexagonal prisms.

Double Sulphite of Sodium and Potassium, $KNaSO_3$.—This was obtained by crystallising equivalent parts of the sulphites of sodium and potassium, and exactly resembles these salts.

Double Sulphite of Potassium and Ammonium.—Sulphite of potassium was evaporated with a large excess of sulphite of ammonium. If equivalent quantities be taken, almost pure potassium metasulphite first crystallises out, and then a mixture of potassium and ammonium sulphites. The salt crystallises in hexagonal prisms.

Acid Bisulphite of Sodium and Potassium—

This salt was prepared by saturating two equivalents of carbonate of soda with sulphurous acid, and then adding one equivalent of potassium carbonate. The salt is very soluble in water, and it cannot be dehydrated without decomposition. The crystalline form could not be determined.

Acid Bisulphite of Sodium and Ammonium—

A current of ammonia was passed into a saturated solution of bisulphite of sodium, when crystals of this body at once separated. It is stated that the heat of solution of the metasulphite of sodium when freshly prepared is different from that of the metasulphite which has been prepared for some time, and hence that this latter must be an isomeric modification of the metasulphite.—S. G. R.

“Kaliborite,” a New Mineral. W. Feit. Chem. Zeit. **13**, 1188.

SEVERAL years ago Staute discovered the mineral pinnoite at Stassfurt (Ber. **17**, 1584). The present author has noticed, in Schmidtmannshall, white masses which resemble pinnoite except in fracture. In this particular they resemble kieserite, and like kieserite, fall to powder in water. The powder, on examination under the microscope, was found to consist of small particles, on which no crystal faces could be distinguished. Analysis showed the constituents to be potassium, magnesium, boric acid, water,

and a very small quantity of chlorine (as sodium chloride). The new mineral has been named "Kaliborite," as hitherto no mineral has been known containing potassium combined with boric acid. Several analyses of the mineral were made, and all agreed well with each other, and with that calculated for the formula, $2 K_2B_5O_{10} + 9 MgB_4O_7 + 39 H_2O$, thus:—

	Found.	Calculated.
K ₂ O	6.48	6.42
MgO	12.06	12.28
B ₂ O ₃	57.46	57.34
H ₂ O	24.00	23.96
	100.00	100.00

The disintegration of the mineral in water is due in all probability to the solution of the small quantity of sodium chloride, which acts in the capacity of a binding agent. Water has very little action on "kaliborite," but warm dilute mineral acids dissolve it easily. Its specific gravity is 2.05.—T. L. B.

The Solubility of Salts in the Presence of Acids, Bases and Salts. The Hydrochlorides of the Chlorides. Engel. Ann. Chim. Phys. [6], 17, 338.

THE following are the hydrochlorides of the chlorides as yet known, with the exception of those of the chlorides of mercury:—

(SbCl₃)₂.HCl.2 H₂O
 SbCl₃.5 HCl.11 H₂O
 (BiCl₃)₂.HCl.3 H₂O
 (ZnCl₂)₂.HCl.2 H₂O
 (ZnCl₂)₂.2 HCl.4 H₂O
 CuCl₂.HCl.3 H₂O
 CuCl₂.2 HCl.5 H₂O
 CdCl₂.2 HCl.7 H₂O
 Fe₂Cl₆.2 HCl.4 H₂O
 AuCl₃.HCl.4 H₂O
 PtCl₄.2 HCl.6 H₂O
 SnCl₄.2 HCl.6 H₂O
 SnCl₂.HCl.3 H₂O

From this it is seen that:—

- (1.) All the hydrochlorides of the chlorides contain water.
- (2.) The smallest quantity of water is 2 mol. for each molecule of HCl.
- (3.) When the hydrochloric acid combines at the same temperature with a varying number of molecules of a chloride the amount of water increases at the rate of 2 mol. of water for each additional molecule of HCl.

The facts seem to point to the conclusion that in these compounds the hydrochloric acid exists as the hydrate HCl.2 H₂O, combined with either anhydrous or hydrated chlorides. This is rendered all the more probable, as the hydrate HCl.2 H₂O has been obtained in the crystalline state. Such a consideration is perfectly applicable to all the salts given above, with the exception of the hydrochlorides of the chlorides of bismuth and cadmium; it would be necessary to assume the existence of (BiCl₃)₂.H₂O and CdCl₂.3 H₂O.

Bismuth chloride, however, is anhydrous, and cadmium chloride crystallises with two, not three, molecules of water. It is possible, however, that some decomposition may go on after formation of the hydrochloride.

Mercuric chloride, which forms anhydrous crystals, gives rise to a series of hydrochlorides containing more than two mols. of water for each molecule of HCl.

HgCl₂.2 HCl.7 H₂O
 (HgCl₂)₃.4 HCl.14 H₂O
 (HgCl₂)₂.HCl.6 H₂O
 (HgCl₂)₃.HCl.4.5 H₂O
 (HgCl₂)₃.HCl.5 H₂O

It may be noted that—

- (a) no hydrochloride of a chloride is insoluble;
- (b) the solubility of these salts is greater than that of the corresponding chloride, cupric chloride excepted;
- (c) the increase in the solubility of certain chlorides in presence of hydrochloric acid must thus depend on the formation of a hydrochloride, which can generally be isolated.

—T. L. B.

On the Action of Hydrochloric Acid on the Solubility of Cuprous and Lead Chlorides. R. Engel. Bull. Soc. Chim. [3], 1, 693—695.

THE author gives a comparative table of experiments made on the solubility of cuprous chloride by Chatelier and himself.

Quantity of cuprous chloride in 10 cc. of saturated solution in presence of various quantities of hydrochloric acid.

EXPERIMENTS OF LE CHATELIER.

T = 17° C.			T = 0° C.		
Density.	$\frac{Cu_2Cl_2}{2}$	HCl.	Density.	$\frac{Cu_2Cl_2}{2}$	HCl.
...	0.475	8.975	1.04
1.050	1.4	15.7	1.04	1.5	17.5
...	1.575	18.2	1.065	2.9	26.0
1.080	4.5	34.5	1.132	8.25	44.75
1.135	8.25	47.8	1.261	15.5	68.5
...	11.5	57.0	1.345	33.0	104.0

The figures give the number of $\frac{1}{1000}$ equivalents of cuprous chloride and hydrochloric acid in 10 cc. of the liquid.

Lead Chloride.—The following table shows the solubility of lead chloride in presence of varying quantities of hydrochloric acid in a saturated solution of 10 cc.

PbCl ₂ .	HCl.	Sum of Equivalents.
0.42	0.42
0.22	0.35	0.57
0.125	0.675	0.800
0.11	1.125	1.235
0.103	1.5
0.099	2.3
0.090	3.4
0.08	4.5
0.072	5.8
0.088	11.7
0.100	29.5
0.209	46.7
0.95	72.0
1.9	96.0
3.01	111.5

The figures represent the number of $\frac{1}{1000}$ equivalents of lead chloride and hydrochloric acid. The table is sufficiently clear without any further comment.—A. L.

PATENTS.

Improvements in Furnaces and Apparatus for Heating Pots and Crucibles. W. G. Foster, Streatham Common. Eng. Pat. 14,394, October 6, 1888. 8d.

THE furnace consists of a conical or dome-shaped well of brickwork, into which the pot is lowered from the top by means of a convenient arrangement of chains or rods. Immediately below the pot (in position) is a circular fire, resting on bars radiating outwards from a central pier of brickwork, the height of which regulates the depth of the fire. The fuel—preferably gas coke—is charged in from the top of the furnace.—A. R. D.

Process and Apparatus for Producing Phosphorus. J. Readman, Edinburgh. Eng. Pat. 14,962, October 18, 1888. 8d.

THIS invention relates to a process for obtaining phosphorus by subjecting materials containing phosphoric acid or acid phosphate of lime, incorporated with carbon or carbonaceous matter, to heat generated by the electric current, and applied directly to the materials contained within a furnace.

—C. N. H.

Improvements in or appertaining to the Separation of Chlorate of Potash (and, if desirable, the Chloride of Calcium or Magnesium, or other similar Salt in the Mother-Liquor) from Solutions thereof. J. R. Wylde, M. J. Hammill, and H. Auer, Widnes. Eng. Pat. 15,097, October 20, 1888. 4d.

A CONSIDERABLE loss of potassium chlorate arises in its manufacture from its solubility in the calcium or magnesium chloride mother-liquors. The inventors refrigerate the mixture, which, from the former process, should have a specific gravity of about 72° Tw., and from the latter of about 51° Tw. to 0° F. A considerable further crop of chlorate crystals is thus obtained. The operation lasts about a week. By still further cooling, the chlorides of calcium and magnesium in combination with six molecules of water, can be crystallised out.—S. G. R.

Improvements in the Production of Carbonate of Soda. H. W. Wallis, London. Eng. Pat. 15,367, October 25, 1888. 4d.

WHEN lead has been reduced from its sulphur compounds by fusion with an alkali, the slag contains the alkali as sulphide. This is dissolved in water, and carbon dioxide passed in with the production of the carbonate of the alkali; the sulphuretted hydrogen liberated can be used for precipitating metals, such as copper, as sulphides from their solution.

—S. G. R.

Improvements in or Connected with the Concentrating of Caustic Alkali and other Liquors by Multiple-Effect or Yargun Plant, for the Purpose of Preventing Incrustation or Deposit in or on the Tubes. G. H. Bolton and J. R. Wylde, Widnes. Eng. Pat. 15,624, October 30, 1888. 4d.

IN order to free the liquors which are to be concentrated from matter in suspension, they are passed through mineral filter beds. The liquors can then be concentrated by the multiple-effect system of evaporation, i.e., passing the liquors through a large number of pipes of small diameter and surrounded by steam, without risk of clogging the small pipes by the deposition of insoluble matter.—S. G. R.

Improvements in Treating a Product obtained from Sea-Weed. R. H. Steedman, Dumbarton. Eng. Pat. 15,815, November 2, 1888. 4d.

IN the evaporation of the liquors obtained by the lixiviation of kelp, a salt termed kelp-salt is produced. To this there is added, either when in solution in the original liquor, or after the salt has been redissolved, chloride of calcium or the chlorides of other metals, such as magnesium, strontium,

and barium. Calcium carbonate is thus precipitated with the formation of chlorides of sodium and potassium, which can be used in the manufacture of alkali.—S. G. R.

Improvements in the Construction of Ammonia Stills. G. E. Davis, Manchester. Eng. Pat. 16,349, November 12, 1888. 8d.

IN this improved apparatus the cap or rose by which steam is passed into the layer of liquor on each shelf of the ammonia stills has a deeply sinuous outline, through which pass the perforations by which the steam is distributed. In Fig. 1, A represents the rose, S the stops cast upon the

Fig. 1

plate b, to ensure a still further control over the path of the steam. Fig. 2 represents the column still, in which is

Fig. 2.

included the liming box. The upper trays hold the liquors containing free ammonia, and which is here evolved. The

liquors then pass, by the pipe C, to the chamber L. This is filled with milk of lime by the pipe G, kept agitated by the steam pipe E. The milk of lime and the liquors which now contain only fixed ammonia, pass to the lower trays by pipe D, are there steamed, and the ammonia then given off passes up through the pipe B to the exit. The spent liquors are run off by the U-shaped pipes F. (See this Journal, 1888, 719.)

—S. G. R.

Improvements in Apparatus for the Manufacture of Salt.

H. H. Lake, London. From J. L. Alberger, H. Williams, and L. R. Alberger, New York. Eng. Pat. 6118, April 9, 1889. 8d.

The operations which are carried on within the apparatus will be best learned from a description of the plant. There are four tubular heaters, A and A', B and C. The heaters A and A' are heated by steam brought to them by the pipe S, whilst B and C are heated by the waste steam from the

evaporators D and E, carried to them by the pipes S' and S''. The brine is raised to a temperature of about 300° F. under hydraulic pressure. Any lime present as sulphate or carbonate is found to become insoluble, and will crystallise on a suitable surface. The brine is therefore passed through the purifiers F and G, only one of which is in use at a given time. The purifiers are charged with gravel at the top, the deposited lime and the gravel being removed from the bottom. From the purifiers the brine passes to the evaporators D and E, and thence at a temperature of about 226° F. to the "grainer" H by the pipe P'. The grainer is a circular iron pan, within which the brine is forced to travel in a circular direction, and is furnished with two revolving arms. To the one, R, are attached scrapers L, which move the salt as it separates towards the vessel I. To the other arm are attached small pendant chains, W, carrying small metal plates which just plunge below the surface of the brine. The brine is heated by pipes (not shown in figure) which have a superficial area about two-thirds that of the brine covering them.

The salt passes from the vessel I to the centrifugal J, thence by the elevator N to the "bolts" XX where it is separated into the right sizes. The mother-liquors are run into the tank Z, into which the fresh brine is also fed, and then by the pump A' and pipe P' to the steam-jacketed pipe P'', which carries off the brine from the grainer to the heater C, and thence to the pump A'', and so back again to the other heaters. It is found to be necessary to pass the brine through the heater C to prevent the choking of the pump A' by deposited crystals of salt. The purifiers F and G act so efficiently that only about 0.044 per cent. of calcium salts are left in the brine.—S. G. R.

Process for Removing Salts of Calcium, Magnesium and other Metals from Aqueous Solutions. C. A. Doremus, New York, U.S.A. Eng. Pat. 8883, May 28, 1889. 6d.

For waters either temporarily or permanently hard, the inventor adds some fluoride such as sodium fluoride, whereby the calcium and magnesium are completely precipitated. If much calcium or magnesium be present, then the water may be first treated by Clark's process with subsequent addition of the fluoride, thus lessening the amount of the latter required. It is stated that any fluoride of calcium or magnesium which may remain in suspension does not produce with soap a precipitate containing any fatty acid,

whereas under the same circumstances the carbonate of these bases do form insoluble precipitates. Attention is called to the imperfect manner in which other bodies act when used for purifying waters.—S. G. R.

A Process for Preparing Plumbates of Calcium, Barium and Strontium, and employing the same for Oxidising Purposes, and for producing Oxygen and other Bodies. C. Huelser, London. From G. Kassner, Breslau, Germany. Eng. Pat. 11,899, July 26, 1889. 6d.

The carbonate, oxide or hydrate of calcium is fused with the oxides or carbonates of lead, when plumbate of calcium is formed, Ca_2PbO_4 . In a similar way the plumbates of strontium and barium are prepared. These bodies can be used as oxidising agents in various ways. They may be suspended in water and boiled with the bodies to be acted upon either with or without the simultaneous passage of carbon dioxide. They can be heated with carbonated salts under pressure, whereby the salts are obtained as hydrates, and the lead as peroxide, and this insoluble residue of lead peroxide and calcium carbonate is allowed to act on the body to be oxidised. Other applications are given, but in principle they all rest on the oxidising power of lead peroxide either *per se* or in combination.—S. G. R.

An Improved Mixture for Use in Apparatus for Producing Cold. J. Y. Johnson, London. From "La Compagnie Industrielle des Procédés Raoul Pictet of Paris, France." Eng. Pat. 12,514, August 7, 1889. 6d.

In this invention a mixture containing carbonic and sulphurous acids in certain proportions is substituted for the liquid sulphurous acid, SO_2 , usually employed in refrigerating machines, and is obtained by causing gaseous carbonic acid to bubble through liquid sulphurous acid at a low temperature. To determine the exact quantity of carbonic acid to be dissolved in the sulphurous acid it is necessary to take into consideration at the same time: (1.) The lowering of the boiling point of the mixture; and (2.) The dynamic or mechanical work done by the apparatus employed to liquefy the mixture. The advantages claimed for this mixture are: (1.) For a given quantity of cold to be produced a smaller compressing pump can be employed; and (2.) At the same time the amount of work necessary to produce cold is diminished. The invention is illustrated by curve diagrams.—E. S.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

The Manufacture of Red Glass for Church Windows (12th and 13th Centuries). C. E. Guignet and L. Magne. Compt. Rend. 109, 448—451.

THE secret of this manufacture was only recovered by Boutemps in 1826, who showed that the red colour was due to the presence of cuprous oxide. The modern manufacture, however, is not equal to that of early times. The authors show that the glass of the 12th and 13th centuries may be divided into three main classes.

1. Glass veined on the surface. These markings are only on the one surface, and have been produced during the blowing by the spreading out and flattening of the glass, due to centrifugal force, at the end of the blow pipe.

2. Glass coloured in the middle. This was obtained by fusing a very thin layer of red glass between two colourless surfaces. The effect is much finer than that obtained by the present method of flashing, i.e., having the coloured glass outside and the colourless within.

3. Glass marbled in its substance. This was of two kinds. In the one case the markings were bent, twisted and turned back on themselves in no sort of order, whilst in the other the colours occurred in exceedingly thin layers always parallel to one another, and the whole wavy in outline. The colour is made up of different shades of red, and the veinings are only red on the surface. They have been produced by glass of a yellowish tint arising from the presence of protoxide of iron coming in contact with the greenish-blue glass due to cupric oxide. The great beauty of this glass seems, therefore, to depend on the use of two coloured glasses.—S. G. R.

The Variations in the Zero-Points of Thermometers made of Jena Normal Glass. F. Allihn. Zeits. Anal. Chem. 28, 435—438.

EXPERIENCE has shown that the zero-points of thermometers are liable to considerable variations. It is found that thermometers made of glass containing fair quantities of both potash and soda are very subject to this after-effect, whilst glass containing only one alkali is much less irregular in its behaviour (this Journal, 1888, 438). This after-effect consists partly of a temporary depression of the zero-point, and partly of a permanent increase of the same. The first phenomenon is observed when a heated thermometer is suddenly cooled. The bulb of the instrument takes some time to return to its original size. In the case of thermometers made of Jena glass this takes place in 2—3 days; ordinary

thermometers require weeks, and even months, to return to their original size. The temporary depression of the zero-point averages 0.05° for instruments made of Jena glass, 0.4° for Thuringian glass thermometers, and 0.15° for English glass (containing lead) thermometers. A number of experiments were made with thermometers constructed of Jena glass. Its composition is:—

	Per Cent.
Zinc oxide	7
Lime	7
Soda	14½
Alumina	2½
Boric acid	2
Silica	67

The results of these experiments are given below:—

Thermometer used.	First Determination of the Zero-Point shortly after Manufacture.	Second Determination of the Zero-Point after Long Storage.	Rise of the Zero-Point.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Permeability of Cements and Cement-Mortars under Pressure. L. M. Haupt. Jour. Franklin Inst. 1889, 199.

THE experiments here noticed were made by G. W. Hyde and W. J. Smith, University of Pennsylvania, by means of four cylinders 3 in. in diameter, in which the specimens to be tested were placed, joined to a 3-in. main pipe, through which the pressure was transmitted to the specimens from a hand-pump at one end. The specimens were 3 in. thick. The pressure was maintained at three degrees—75 lb., 100 lb., and 200 lb. per square inch respectively—and for three hours in each experiment. Six series of experiments were made: with neat cements, after setting seven days and after setting 28 days; cement-mortars, composed of equal parts of cement and sand, after seven days and after 28 days; and cement-mortars mixed in the proportions of 1 to 2, after seven days and after 28 days. The samples were allowed to drain for one day. Each sample of cement was sifted through a sieve of 40 meshes to the lineal inch. The sand was passed through a sieve of 25 meshes to the inch. Eight brands of cement were tested.

The results are given in several large tables, with diagram curves of discharge of water, from which the following table is made out:—

DISCHARGE OF WATER THROUGH SAMPLES UNDER PRESSURE.

Sample.	Number of Samples.	Pressure per Square Inch.		
		75 Lb.	100 Lb.	200 Lb.
		Water passed per Square Inch in 24 Hours.		
Neat cement, 7 days....	5	Quarts. 0'033 to 0'091	Quarts. 0'006 to 0'092	Quarts. 0'019 to 0'267
Neat cement, 28 days...	1	0'034	0'052	0'138
Mortar, 7 days.....	3	1'503 to 12'397	2'336 to 17'096	6'323 to 36'297
Mixture, 1 to 1.....				
Mortar, 7 days.....	5	2'107 to 42'546	3'310 to 52'554	10'508 to 101'268

The Manufacture and Properties of the Cements of the Isère. A. Gobin. *Annales des Ponts et Chaussées*, **17**, 1889, 755, through Abstr. Papers Inst. Civil Eng. **48**, iv. 8.

In the Department of the Isère in France are a number of deposits of argillaceous limestones, suitable for the manufacture of hydraulic cements. This paper describes the most important deposits in detail, together with the processes of manufacture, and the resulting products in each case. One of the oldest known deposits is that of Porte-de-France, near Grenoble, on the right bank of the Isère. This was discovered in 1842, and has since been worked by various firms. There are three layers, belonging to the lower cretaceous series, their position being nearly vertical. One of them is 14 ft. 9 in. thick, and each of the other two about 5 ft. The stone is extracted through underground workings, by means of a wire rope-way. The cables are 600 metres (656 yards) long, and the difference in level between the two extremities is 310 metres (339 yards). The tension is regulated by means of a moveable truck loaded with 2,000 kilos. (1 ton 19 cwt.), and attached to the lower end of the cable. The speed is controlled by a Prony brake.

The limestone is burnt in continuous kilns by pulverised anthracite, which is wetted previous to use. The stone is reduced to pieces of uniform size to ensure regularity in burning. The consumption of fuel is 180 kilos. (397 lb.) per ton of stone, and the operation lasts 10 days. On leaving the kiln about two-thirds of the charge consists of yellowish fragments, retaining their original shape. This forms the quick-setting cement. The remaining third is composed of black heavy clinker, which is picked out by hand, and used for making the slow-setting cement.

Both kinds of cement are ground in ordinary horizontal mills 1·70 metres (5 ft. 7 in.) in diameter, and making 70 revolutions a minute. The quick-setting cement is sifted through a No. 50 sieve, and passed into stores, where it is kept two or three months. The cement has a density, when not shaken down, of 1·15, and sets in from five to 10 minutes, according to the prevailing temperature. The slow-setting cement, called natural Portland, is sifted through a No. 60 sieve, and then stored for three or four months at least before being issued. It sets in 15 to 20 minutes. Although the bulk of this natural Portland is a by-product from the manufacture of the quick-setting cement, yet the greater part of the charge of the kilns can be obtained as clinker

by augmenting the proportion of fuel to 250 kilos. (551 lb.) per ton. In this case the burning is intermittent, and any yellow fragments must be picked out by hand. The burning takes 21 days.

This slow-setting cement has a density of 1·4, when not shaken down, and sets in from 15 to 20 minutes.

An artificial Portland cement is also made at Porte-de-France. The materials used are the waste from the manufacture of hydraulic lime, and the clinker which gives the natural Portland cement. Four parts of the waste are ground with six parts of clinker, and the resulting powder is stored for at least four months before use. Cement made in this way has a density of 1·35, and sets in three hours. At these works a new grinding apparatus has been introduced to take the place of the horizontal mills. It consists of a vertical cylinder 1 metre (3·28 ft.) in diameter, within which a shaft, provided with six arms, revolves, carrying with it six loose steel balls, each 0·20 metre (7·87 in.) in diameter, and weighing 35 kilos. (77 lb. each). The upper part of the cylinder is furnished with a wire sieve, through which the ground product passes. The speed is 180 to 200 revolutions a minute. The power required is said to be less than with the ordinary horizontal mills.

In some of the factories a conical sieve is in use, which contains only 3 square metres (3·588 square yards) of wire netting. Eight of these sieves are required for three pairs of stones.

During the process of manufacture numerous samples are taken and tested. Should any of these samples show signs of weakness when immersed in water for eight or ten days, the bulk of the cement is retained in store until renewed tests show it to be reliable.

Analyses of the materials and finished cements are given, from which it appears that the two natural cements contain about 56 per cent. of lime, while the artificial Portland contains 57 per cent. The amount of magnesia in the Portland cement is 2·4 per cent., and of sulphuric acid 1·8 per cent.

At Voreppe, near Grenoble, four kinds of cement are made. The materials are of the same geological formation as at Porte-de-France, but the layers are inclined at an angle of 45°. They are worked by means of inclined underground galleries.

The kilns are 10 metres (32·8 ft.) in height, and the draught is increased by means of a main chimney, connected by flues with the kilns. The draught is further regulated by iron covers to the kilns, which can be raised or lowered as required. The fuel used is anthracite, with a little steam coal. For the quick-setting cements the working of the kilns is continuous, and for the Portland cement intermittent. The general process of manufacture is similar to that adopted at Porte-de-France, and the finished cement is stored at least six months before being issued. The sieves used are flat, inclined at an angle of 45°, and are kept in a state of vibration.

In chemical composition these cements differ but little from those of Porte-de-France. The Portland cements are slightly richer in lime, and consequently set more slowly. The crushing strength per square centimetre of the slow-setting Portland cement is 129 kilos. per square centimetre (1,834 lb. per square inch) in 10 days, and 458 kilos. (6,514 lb. per square inch) in one year.

At Grenoble and Tonnay six kinds of cement are manufactured, the time of setting of which varies from three minutes to three hours. Here again the materials belong to the same geological formation as those of Porte-de-France. The bulk of the cement is made from a layer of limestone 1·50 metres (14·76 ft.) thick, containing about 24 per cent. of clay. The outer portions of this layer contain a larger proportion of carbonate of lime, and can be distinguished after burning. They are picked out by hand, shaken by sprinkling with water, and afterwards ground and sifted.

The artificial Portland cement is made of a mixture of three materials, viz., the waste from the manufacture of hydraulic lime, clinker produced during the burning of the quick-setting cement, and clinker made of an artificial mixture of marl and limestone. The latter mixture is burnt for a fortnight in intermittent kilns. The finished Portland cement contains 50 per cent. of lime and 3 per cent. of

magnesia. The tensile-strength of the neat cement in 28 days is 48·6 kilos. per square centimetre (691 lb. per square inch).

A limestone belonging to the Lias formation yields the raw material for two varieties of cement manufactured at Valbonnais. The layer used is 4 metres (13 ft.) in thickness, and is worked through three galleries, the lower of which forms an inclined plane. The stone is burnt in kilns working continuously, and the product is afterwards picked by hand. The harder clinkers yield a slow-setting cement, which is stored two or three months before use. The percentage of lime in this Portland cement is 55·7, and of magnesia 0·5. Sulphuric acid is present to the extent of 2 per cent. At La Mure, a church, 52 metres (170·5 ft.) in length, is being built almost entirely of concrete blocks made with this cement.

Vicat's slow-setting Portland cement has been made since 1857 at Genevray, near Grenoble. The original factory was pulled down last year to make room for the new stores. The raw materials are a rich lime, made by burning a pure limestone, and a highly argillaceous limestone, containing 40 per cent. of clay. These two are mixed in such proportions that 23 parts of clay would unite with 77 parts of carbonate of lime. The argillaceous limestone is heated at a temperature which is too low to expel the carbonic acid, and is then ground and sifted through a No. 55 sieve. An automatic apparatus takes a sample from each sack of ground material. These samples are analysed, and serve to regulate the proportions of the mixture. The rich limestone is first burnt, then slaked by placing in perforated iron vessels, which are immersed for an instant in water. The contents are then discharged upon a grating, where the lime slakes and falls through, leaving the slags and imperfectly-burned pieces upon the grating. In six or seven days the slaked lime is sifted through a No. 60 sieve and removed to stores, where samples are taken for analysis. The pulverised raw materials are mixed by weight in proportions dependent upon the chemical composition. The mixed powder is then moistened, moulded into bricks and dried in the open air. The kilns, which are 42 in number, have a total height of 10·50 metres (34 ft.), and a diameter of 2·50 metres (9·2 ft.) or 3 metres (9·84 ft.). Before charging into the kiln the bricks are broken into small fragments, which are arranged in layers alternately with anthracite. The proportion of fuel used is one-sixth of the weight of the briquettes, and varies in different parts of the kiln. The clinker from the kilns is first broken in a stone-crusher, and ground in mills of the usual type. The cement is then sifted through a No. 60 sieve. Samples of the finished product are taken, and the briquettes are not only tested for tensile-strength but are frequently analysed as a check upon the proportions of the raw materials. The tensile-strength of a mixture of one part by weight of cement with three parts by weight of standard sand is also ascertained. The sand is prepared by sifting siliceous sand through a sieve of 64 meshes per square centimetre (413 meshes per square inch). That which passes through is again sifted through a sieve of 144 meshes per square centimetre (929 meshes per square inch), and the sand remaining upon the latter is used for the experiments. Each series of tests is made with 44 briquettes of a breaking section of 16 square centimetres (2·48 square inches). These are broken at periods varying from five days to a year, the same system having been carried out since the establishment of the factory. The time of setting of this cement varies from 8 to 24 hours, according to the temperature. The percentage of lime is 61·25, of magnesia, 1·90, and of sulphuric acid, 1·70. The tensile-strength of the neat cement in 28 days is 33·83 kilos. per square centimetre (481·16 lb. per square inch), and the crushing-strength in the same time 372·3 kilos. per square centimetre (5,295·16 lb. per square inch). Mixed with three parts of sand, the figures are 19·67 kilos. per square centimetre (365·5 lb. per square inch) and 177·3 kilos. per square centimetre (2,521·7 lb. per square inch) respectively.

At Uriage a natural cement is made by the same firm from a limestone of the Lias formation. This stone is traversed by irregular white veins of carbonate of lime, which are carefully picked out before burning. The kilns

are 6 metres (19·68 ft.) high, and 3 metres (9·84 ft.) in diameter, and are worked continuously. The manufacture of this cement is similar to that of the other natural cements of this district. The finished product contains 47·30 per cent. of lime, and 1·95 of magnesia, with 2·20 per cent. of sulphuric acid.

Near La Grande Chartreuse two kinds of cement are manufactured from a layer 3 metres (9·84 ft.) thick, belonging to the Neocomian formation. The strata are inclined at an angle of 43°, and the stone is extracted through 22 galleries, each 3·50 metres (11·48 ft.) in height. The difference in the quality of the two cements produced here is chiefly due to the mode of burning. The heavy, or slow-burning, cement is burned for three weeks, during which process about 10 per cent. of dust is produced, which is rejected. The proportion of lime in these cements is 54·5, of magnesia, 3·5, and of sulphuric acid 4 per cent.

The quick-setting Grenoble cements are largely used for gas- and water-pipes, sewers, and other hydraulic work which must be executed rapidly. The general composition of the concrete is one part, by volume, of gravel to one of cement.

Referring to the discrepancies so frequently noticed in the weights of the same cements when taken by different observers, the author proposes to weigh a given volume of cement after it has been subjected to a series of 250 or 300 shocks in a litre vessel of metal 0·172 metre (0·564 ft.) in height, and 0·086 metre (0·282 ft.) in diameter. The cement should fill the measure loosely at the commencement of the experiment, and the distance to which it sinks when shaken down will be an indication of the relation between the weight when weighed in the loose state and when packed. It was found that the density of a cement did not perceptibly increase when the number of shocks given to the vessel was greater than 300. The increase in density by this method was about 30 per cent., as compared with the powder measured loose. The microscopic examination of a cement is recommended as a means of detecting impurities, and of controlling the fineness of grinding.

In storing the ground cement, it has been noticed that there is an increase of temperature of about 8° C. (14·4° F.), especially during moist weather. Storing the cements for two or three months before using is general, and appears to be necessary. With the Portland cements especially the time of setting is considerably increased by storing. In the cements examined, the percentage of sulphuric acid varied from 1·65 to 3·70. Experience has shown that even 4 per cent. of this substance has no injurious effect when the cement is used in fresh water. When exposed to salt water, so high a proportion of sulphuric acid would prove injurious, owing to the formation of sulphate of magnesia.

The Manufacture of Slag Cement. J. Grosclaude. *Annales Industrielles*, 1889, 89, through Abstr. Papers Inst. Civil Eng. 48, iv. 12.

THE manufacture of cement from slag has, in the last few years, become rapidly extended, and works are now in operation in France at Saulnes and Marnaval, in England at Middlesbrough, in Switzerland at Choindez, at many places in Germany, and at Bilbao in Spain. The quality of the cement varies considerably in accordance with the composition of the raw products employed, and the care exercised in the manufacture, but the material when well made will bear comparison with the best Portland cement. The slag employed should be basic, and must be previously granulated on the system of Mr. C. Wood, as otherwise it is devoid of hydraulic properties. According to Professor Tetmajer, of Zurich, the lime, silica, and alumina in the slag should bear to one another approximately the following proportions, as 46, 30, 16. Fat or pure limes are generally selected to add to the slag, but the author counsels the adoption of poor or clayey limes in cases where the cement is to be used above ground. Where much calcium sulphide is present, as in the Bilbao slags, the cement takes a greenish tinge, but this does not impair its quality. A sample, tested by Professor Tetmajer, composed of 100

parts of Bilbao slag and 15 parts of lime, was found, on analysis, to give the following percentage results:—Silica, 30.56; alumina, 13.31; oxide of iron, 0.25; oxide of manganese, 1.74; oxide of lime, 45.01; magnesia, 2.96; sulphate of lime, 1.41; and sulphide of calcium, 4.63. Briquettes of the neat cement were tested as follows:—

	Seven Days.	Twenty-eight Days.
	Kilos.	Kilos.
Strength in compression per square centimetre:—		
In water.....	96.9	120.0
In air.....	..	141.0
Tensile strength per square centimetre:—		
In water.....	19.3	28.7
In air.....	..	19.5

The mode of preparing the slaked lime, and the apparatus used for the purpose, is explained by reference to diagrams. Drawings are given of various descriptions of drying machines which have been employed for desiccating the granulated slag; the rotary drier, invented by Mr. Ruelle, is preferred by the author, and a novel form of apparatus, patented by Mr. Raty, of Saulnes, is described and fully illustrated. For the intimate admixture of the slag and slaked lime, and for grinding the same to a fine powder, the apparatus of Mr. Luther, of Brunswick, is employed. This consists of an iron cylinder, with a corrugated lining, partly filled with small metal balls, by means of which the materials are both ground and mixed in one operation, which lasts about three-quarters of an hour for each charge. The cement thus prepared leaves a residue of from 5 to 6 per cent. on a sieve of 2,500 meshes per square centimetre. A sample of slag cement made at the Donjon factory was officially tested at the École des Ponts et Chaussées in September 1888, with the following percentage results:—Combined silica, 23.85; alumina, 13.95; peroxide of iron, 1.10; lime, 51.40; magnesia, 1.95; sulphuric acid, 0.45; sand, 0.25; loss on ignition, 7.05. It left on a sieve of 5,000 meshes per square centimetre a residue of 23 per cent.; gauged with 28 per cent. of water, the initial set took place in one and a quarter hour, and the set was complete at the end of three hours. On the mean of six tests the neat cement showed the following tensile strength per square centimetre:—In 7 days, 21.87 kilos.; in 28 days, 26.88; and in 84 days, 31.15 kilos. (equivalent per square inch to 311.06 lb., 382.32 lb., and 443.05 lb. respectively). Briquettes of three parts sand to one cement broke in 7 days at 14.93 kilos., in 28 days at 26.03, and in 84 days at 29.23 kilos. (equivalent per square inch to 212.35 lb., 370.23 lb., and 415.74 lb. respectively). Tables, too long for abstract, indicate the composition of 23 different samples of slags from various foreign furnaces, together with tests of the cements made from the same.

An estimate is given of the cost of the plant for a works capable of producing 6,000 tons of cement per annum, and of the necessary materials for the same, also of the expense of manufacturing the cement and the profits on the manufacture. The estimate is accompanied by plans and sections of the factory.

Utilisation of Waste Products. Wochenschr. des öst. Ing. und Archit. Ver. 1889, 215, through Abstr. Papers Inst. Civil Eng. 48, iv. 14.

THE author shows that a good and useful building material may be produced by roasting, at a temperature of 302° F., the rubbish obtained from old buildings; that by such process so much water is driven out of the material as to reduce the volume from 20 to 40 per cent., and hence the employment of such a perfectly dry material in a building will prevent the settlements so often observed, resulting from the drying of the material within the walls of the building itself. A further advantage is a sanitary one, for while the original waste product may contain within itself

the germs of disease, these are destroyed by the intense heat to which they are subjected in roasting, and the material is therefore completely disinfected.

Another useful building material is manufactured from blast furnace refuse in the form of bricks and paving slabs, and this has established a new industry in the smelting houses on the Schwechat, near Vienna, where the furnace slag is broken up and mixed with hydraulic lime, and then moulded under steam pressure into bricks. The value of the product consists in the formation of silicate of lime from the combination of the silica in the slag with the lime, resulting in a hard material, which increases in hardness on exposure. The brick in this condition is of a uniformly greyish-white colour of rather coarse grain and very sharp edges, and possesses in a high degree the two valuable properties of permeability and porosity, and thus constitutes an essentially healthy building material. The durability of the material, too, has been tested by a 15 years' exposure in some cases, and no signs of wear or weathering have been noticed; in short, the results of its employment have been so favourable that it has been recommended by the Board of Works for general purposes, and to be used with a mortar made from slag, sand, and hydraulic lime.

Paving slabs are now made according to a patent process by mixing furnace slag with Portland cement and other constituents, which produce rapid hardening and great strength, and such pavements are now laid down for special purposes in London, Paris, and Vienna.

X.—METALLURGY.

Investigations on Cobalt and Nickel. G. Krüss and F. W. Schmidt. Ber. 22, 2026—2028.

THE authors have continued their investigations on this subject (see this Journal, 1889, 307) and confirm their former communication. The nickel salts employed gave no reactions indicative of the presence of any known impurity, before they were resolved into the two constituents by any of the methods previously described. Fractional precipitation as basic ammonium arsenite resolves nickel into two constituent portions, one of which possesses a lower, the other a higher, atomic weight than that of ordinary nickel (58.6). The lower atomic weight varies between 56 and 58, the higher between 61 and 100; these were determined by reducing the oxides of the corresponding fractions in a current of hydrogen. The metal resulting in both of these cases gave no evidence of the presence of any known impurity, and thus this appears as a confirmation of the composite nature of nickel, but whether the metal is a mixture of two or more elements the authors, who are continuing their work, are unable to say as yet.—C. A. K.

Some Metallic Sulphides. A. Gautier and L. Hallopeau. Compt. Rend. 108, 1111—1113.

METALLIC nickel, treated with carbon bisulphide at a red heat, yields fused masses of the sulphide Ni_2S_3 , and a black powder consisting of the ordinary sulphide NiS , a carbide of nickel and free carbon. The sulphide Ni_2S_3 has a yellow colour and metallic lustre, is not magnetic, is a little harder than fluor spar, easily pulverised, and has a sp. gr. of 5.66. The powder, at first crystalline, loses its metallic lustre and becomes dark green and eventually black. This sulphide is stable hot and cold, slowly attacked by hydrochloric acid or sulphuric acid, rapidly by aqua regia.

Metallic chromium, prepared by Wöhler's process, gives, under like treatment, the ordinary sulphide Cr_2S_3 , as a greyish-black, graphitic substance, mixed with a carbide of chromium, which resists aqua regia.

Lead, at a cherry-red heat, is converted by carbon bisulphide vapour into brilliant cubic crystals of galena. At a higher temperature, some yellowish needles of lead sulphocarbonate are formed.—J. M. H. M.

On the Results of Blast-Furnace Practice with Lime instead of Limestone as Flux. C. Cochrane. Read before Institute Mech. Engineers, October 30, 1889.

To Sir Isaac Lowthian Bell we are indebted for a most carefully conducted series of experiments upon the blast-furnace, recorded in his work entitled "Chemical Phenomena of Iron Smelting." To M. Grüner is the scientific world further indebted for embodying in his "Études sur les Hauts-Fourneaux" the results of those experiments in the most carefully developed mathematical order and algebraical formulae that blast-furnace practice has witnessed. Neither M. Valérius nor MM. Flachet, Barrault, and Petiet have approached Sir Lowthian Bell and M. Grüner in their exposition of the phenomena of the blast-furnace reactions; although, as happens in all scientific progress, those earlier works have been stepping-stones to the great stride accomplished by Sir Lowthian Bell and by M. Grüner. It is true that Sir Lowthian Bell pointed out how the presence of carbonic acid in the gases escaping from the blast-furnace had a distinct bearing upon the economy of fuel consumed in the production of a unit of pig iron; but he further insisted on the fact, as he supposed, that there was an absolute limit to the attainable ratio of carbonic acid to carbonic oxide in the escaping gases beyond which further economy was impossible, by reason of alleged reactions between these two gases as soon as ever that limit was reached. The limit he assigned was one volume of carbonic acid to two volumes of carbonic oxide; which is equivalent to a ratio by weight of three of carbonic acid to four of carbonic oxide, or $\text{CO}_2 : \text{CO} = 0.75 : 1.00$. M. Grüner gave, presumably for the first time, the maximum of perfection possible in any blast-furnace in terms of the maximum ratio of carbonic acid to carbonic oxide; but he seems too readily to have fallen in with Sir Lowthian Bell's idea that there was a practical limit to this ratio, by reason of the reactions which Sir L. Bell alleged took place when the limit was exceeded of one volume of carbonic acid to two of carbonic oxide.

The conclusion drawn by Sir L. Bell is believed by the writer to have been experimentally correct under the conditions under which he assumed the gases to exist in the blast-furnace; but the writer's practice has shown him that there are conditions hitherto unrecorded, which govern the attainable ratio of carbonic acid to carbonic oxide, and it has been his aim for many years past to arrive at the true law which governs the relations of these two gases, and the resulting economy or sacrifice of fuel in the blast-furnace. M. Grüner stated that the ratio of carbonic acid to carbonic oxide was the keynote of the position, and he was right; but it has needed years of practical experience, in the light of Sir Lowthian Bell's analytical experiments and of M. Grüner's inferences, to solve the problem.

There are two leading factors in the conduct of a blast-furnace, which are readily intelligible:—The combustion of carbon at the tuyeres into carbonic oxide wholly, and the reduction of the oxide of iron by the reaction of the carbonic oxide thus produced, so as to form carbonic acid, according to the well-known formula in the case of peroxide of iron—

Now supposing there were no other reactions than these, and that there were needed 15 cwt. of pure carbon to produce 20 cwt. of pure iron, the ratio of carbonic acid to carbonic oxide would be found as follows:— $15 \times 14 \div 6 = 35$ cwt. of carbonic oxide produced at tuyeres; and according to the above formula, for every 56 cwt. of iron, 42 cwt. of carbonic oxide would be required with production of 66 cwt. of carbonic acid. Hence for every 10 cwt. of pure iron there would be required $42 \times 20 \div 56 = 15$ cwt. of carbonic oxide, and there would be produced $15 \times 66 \div 42 = 23.57$ cwt. of carbonic acid. There would therefore be left $35 - 15 = 20$ cwt. of carbonic oxide, and there would be formed 23.57 cwt. of carbonic acid, and the ratio of these would be $\text{CO}_2 : \text{CO} = 23.57 : 20.00 = 1.18$. Now Sir Lowthian Bell's assertion is that such a ratio would be impossible, because the moment the limiting ratio of 0.75 is exceeded, the immediate effect would be to cause a reconversion of

carbonic acid into carbonic oxide, and so to undermine the economy due to such a ratio as the foregoing of 1.18 by the unburning of carbon oxidised to its highest degree. Yet he himself gives an illustration of Styrian furnaces where pig iron is made with from 12 to 15 cwt. of charcoal per 20 cwt. of pig iron produced: so that on the merits of the case there would seem to be something wrong in his deductions. Although as a matter of fact so high a value as 0.75 for the ratio of carbonic acid to carbonic oxide has not been attained with Cleveland ironstone, the author purposes showing that the cause is to be sought deeper than in the mere arbitrary limit assigned to the ratio of carbonic acid to carbonic oxide, and is to be found in reactions of carbonic acid upon red-hot carbon, and in the consequent production of carbonic oxide, so that the ratio $\text{CO}_2 : \text{CO}$ is essentially an effect and not a cause.

In a blast-furnace the perfection of work is that carbonic acid, having once been formed in the process of reduction, should never be allowed to come into contact with red-hot coke; for the immediate reaction between carbonic acid and carbon at a red heat is to convert the carbonic acid into carbonic oxide with most destructive waste of fuel. Thus the units of heat developed by one unit (or cwt.) of carbon burnt into carbonic oxide only are 2,473 (centigrade), whereas the units of heat developed by one unit of carbon burnt into carbonic acid are 8,080; hence the units of heat developed by one unit of carbon in carbonic oxide burnt into carbonic acid are $8,080 - 2,473 = 5,607$. It will thus be seen that, if by any unfavorable reaction in the furnace, such as happens when carbonic acid finds itself in the presence of red-hot coke, any carbonic acid once formed becomes reconverted into carbonic oxide, the unburning of the carbonic acid to carbonic oxide must be accompanied not only by the absorption of carbon but also by serious loss of heat. The reaction which takes place is represented by the formula $\text{CO}_2 + \text{C} = 2 \text{CO}$; in which for every unit of carbon in the carbonic acid a unit of carbon of the coke is dissolved and becomes carbonic oxide; whilst the unit of carbonic acid becomes two units of carbonic oxide by the absorption of the second equivalent of carbon. Just as one unit of carbon as carbonic oxide develops 5,607 heat-units in becoming carbonic acid, so one unit of carbon as carbonic acid in going back to carbonic oxide will absorb 5,607 heat-units, which is equal to the combustion of $5,607 \div 2,473 = 2.26$ units of carbon burnt into carbonic oxide, of which one unit of carbon has absolutely disappeared by absorption in the process, leaving 1.26 units to be supplied and burnt into carbonic oxide at the tuyeres by means of the oxygen in the blast, to compensate for the balance of loss incurred in the region of the furnace in which the reaction has taken place, because by hypothesis the carbonic acid has been evolved or come into contact with red-hot coke under conditions under which it could not exist as carbonic acid. To make the ultimate result, if necessary, yet clearer, the absorption of the one unit of carbon by the carbonic acid to form carbonic oxide will develop 2,473 heat-units, while the reconversion of the carbonic acid to carbonic oxide will subtract from the furnace 5,607 heat-units: so that the balance will be a loss of $5,607 - 2,473 = 3,134$ heat-units, which represent $3,134 \div 2,473 = 1.26$ units of carbon burnt into carbonic oxide. Hence there is a total loss to the efficiency of the furnace of $1.26 + 1.00 = 2.26$ units of carbon burnt into carbonic oxide for every unit of carbon once existing as carbonic acid which shall have been reconverted into carbonic oxide.

When limestone is employed as a flux there are two sources of carbonic acid:—firstly, that contained in the carbonate of lime CaCO_3 , which has necessarily to be evolved in contact with red-hot coke, because at less than a red heat it is impossible to separate the carbonic acid from the lime; and secondly that evolved in the process of reduction of the ore or ironstone, which, if previously calcined so as to become peroxide of iron, undergoes the following reaction: $\text{Fe}_2\text{O}_3 + 3 \text{CO} = \text{Fe}_2 + 3 \text{CO}_2$. Now, according to the construction of the furnace, and the more or less imperfect appliances at command, much or little of the latter, which will be called the carbonic acid of reduction, may be evolved in the same red-hot region in which the carbonic acid from the flux is driven off. In old furnaces

of very small capacity, extravagant waste of fuel took place from this very cause, namely, the evolution of carbonic acid of reduction in the red-hot region, owing to the plunging of the ironstone down into that region before its complete reduction had been effected in a higher and cooler region. How great could be the mischief will appear by assuming the extreme case of a furnace so badly constructed that the whole of the reduction of the peroxide of iron should take place in the red-hot region. From the formula

it will be seen that for the reduction of 56 cwt. of iron there are required 18 cwt. of carbon as carbonic oxide; and 56 : 20 :: 18 : 6.43; therefore 6.43 cwt. of carbon are required for the reduction of 20 cwt. of iron from its assumed condition of peroxide. But inasmuch as 20 cwt. of pig iron contain only 18.80 of pure iron, the carbon required per ton of pig iron will be $6.43 \times 18.80 \div 20 = 6.04$ cwt. Now suppose the whole of this carbon, which should in a perfect furnace pass away as carbonic acid, became carbonic oxide; it would first absorb 6.04 cwt. of carbon for conversion into carbonic oxide according to the reaction $\text{CO}_2 + \text{C} = 2\text{CO}$; and the heat to be furnished at the tuyeres would be $6.04 \times 1.26 = 7.61$ cwt. of carbon burnt into carbonic oxide. Hence a total loss would arise of $7.61 + 6.04 = 13.65$ cwt. of carbon per ton of pig iron.

It was in the direction of reducing this mischievous tendency that, at Middlesbrough especially, important economies ensued on increasing the capacity of the blast-furnace from 6,000 or 7,000 cubic feet to 20,000 cubic feet or more. Thereby more time was given for the reduction of the ironstone; so that it became more possible to secure, in the analysis of the escaping gases when employing limestone as flux, a nearer approach to the presence of the entire quantity of carbonic acid of reduction and in certain cases even the entire quantity. Indeed, M. Grüner was quick to discover in Sir Lowthian Bell's experiments the presence in some cases of a little more carbonic acid than was due to the possible formation of carbonic acid by the reduction of all the ironstone; and the excess must have proceeded from the evolution of carbonic acid from the limestone. As the writer has himself on several occasions since confirmed M. Grüner's observation, he now deems such increase of carbonic acid beyond the carbonic acid of reduction to be the result of a trifling wave of carbonic acid displaced from the surface of the limestone just before it plunges into the red-hot coke region. The amount is so little as not to disturb the main conclusion that the carbonic acid of the flux takes up a weight of carbon practically equal to that which it already contains. Nor must it be lost sight of that in thus taking up carbon and becoming 2CO the result it produces is not altogether prejudicial; for the carbonic oxide so formed enriches the deoxidising gas of the furnace, and promotes the more complete deoxidation of the ironstone in the cooler region above, so as to make it possible to attain to a perfect reduction thereof without absorption of carbon by carbonic acid of reduction.

At this stage it may be interesting to refer to the effect of displacing the carbonic acid from the flux by calcining the latter before employing it in the blast-furnace. The following is a comparison between the results obtained at the same furnace under the two different conditions, and will fully illustrate the benefit to be obtained under favourable conditions by the substitution of lime, CaO , for limestone, CaCO_3 , in a blast-furnace of capacity adapted to the materials employed, although there may seem room for a little regret that the balance of heat received (Table I.) and heat expended (Table II.) is not somewhat closer than here appears.

In these comparative accounts of receipts and expenditure of heat it will be noticed that, in working on limestone, the expenditure falls short by 0.72 cwt. of carbon of the total heat received in fuel and heated blast, and reckoned in carbon burnt to carbonic oxide; whilst in working on lime, the expenditure account shows an excess of 0.81 cwt. of carbon over that which was received. These are errors on either side, amounting to $2\frac{1}{2}$ and 3 per cent. respectively,

to which calculations of this kind are liable, owing to the impossibility of recording accurately all the conditions under which a blast-furnace works. Imperfectly calcined ironstone, for instance, will contain more or less carbonic acid, which if at the surface will pass away as such, but if imprisoned in the core of a large piece of ironstone will descend into the red-hot region of the blast-furnace, there to be liberated with absorption of carbon and resultant loss of heat. Such fluctuations in the ironstone would produce some influence upon the ratio of carbonic acid to carbonic oxide; but all things considered, the above errors of 0.72 and 0.81 cwt. respectively might fairly be spread over the whole of the expenditure account, indeed probably over both receipt and expenditure accounts, and so become inappreciable whilst leaving the salient points of the account undisturbed.

ORMESBY IRON WORKS, MIDDLESBROUGH.

TABLE I.—BLAST-FURNACE of 20,454 cubic feet capacity, and 76 feet height. Comparison between working on limestone and on lime respectively as flux.

Supply of Heat per Ton of Pig Iron made.		Working on	
		Lime-stone.	Lime.
Chemical composition of the escaping gases :—		Per Cent.	Per Cent.

Deduct :—			
Ash7.70 and 7.65		Per cent. 9.07 and 10.59 =	2.09
Sulphur, 0.84 and 0.90			
Moisture 0.53 and 1.95			
Net carbon in coke consumed per ton of pig iron		21.19	17.44
Limestone consumed per ton of pig iron		13.18	{ 7.86 12.28
Deduct foreign matter in flux 3½ and 3.71 per cent.....		0.46	0.45
Net pure carbonate of lime, CaO CO ₂		12.72	11.83

* When working on lime the actual weight of flux charged into the furnace per ton of pig iron made was 7.86 cwt. of impure lime, resulting from the calcination of 12.28 cwt. of raw limestone. The latter was found by analysis to contain 3.71 per cent. of foreign matter, amounting therefore to 0.45 cwt.; and the net pure carbonate of lime was accordingly $12.28 - 0.45 = 11.83$ cwt. of CaO CO_2 , which contained $11.83 \times 22 \div 50 = 5.21$ cwt. of CO_2 . But instead of the whole of this CO_2 being expelled from the limestone in the calcining kiln, the actual weight driven off was only $12.28 - 7.86 = 4.42$ cwt. Consequently there remained in the lime used as flux $5.21 - 4.42 = 0.79$ cwt. of CO_2 ; and this unexpelled CO_2 contained $0.79 \times 6 \div 22 = 0.22$ cwt. of carbon, which corresponds with 1.83 cwt. of CaO CO_2 .

TABLE I.—BLAST FURNACE.—*cont.*

Supply of Heat per Ton of Pig Iron made.	Working on	
	Lime-stone.	Lime.
Carbon contained in flux, $12.72 \times 6 \div 50$ and* $0.79 \times 6 \div 22$	Cwt. 1.52	Cwt. 0.22
Total carbon supplied into furnace per ton of pig iron, $21.19 \div 1.52$ and $17.44 \div 0.22$	22.71	17.06
Deduct carbon absorbed by pig iron	0.60	0.60
Net carbon for producing joint CO_2 and CO	22.11	17.06
Carbon required per ton of pig iron for perfect reduction	6.04	6.04
If all CO_2 passed away without change, total CO_2 in escaping gases would be $(1.52 + 6.04$ $= 7.56) \times 22 \div 6$	27.72	..
and $(0.22 + 6.04 = 6.26) \times 22 \div 6$	22.96
Whilst there would then pass away as CO $(22.11 - 7.56 = 14.55) \times 14 \div 6$	33.95	..
and $(17.06 - 6.26 = 10.80) \times 14 \div 6$	25.20
In that case the furnace would be working perfectly with ratios $\text{CO}_2 : \text{CO} = 27.72 \div$ 33.95 and $22.96 \div 25.20$	Ratio. 0.816	Ratio. 0.911
But the actual working ratios given above were	0.473	0.535
This reduction of ratios, as will be explained further on, is attended with transfer of carbon from condition of CO_2 to that of CO, amounting to	Cwt. 2.44	Cwt. 1.93
The transfer, as will also be explained, is derived from the two following sources:— Carbon from CO_2 of flux, as above	1.52	0.22
Carbon from CO_2 of reduction, by differ- ence	0.92	1.71
Total carbon transferred per ton of pig iron, as above	2.44	1.93
Moisture in atmosphere per cubic foot, grains	4.776	3.243
Weight of air supplied into furnace is found as follows:— Carbon supplied for producing CO_2 and CO, as above	Cwt. 22.11	Cwt. 17.06
Deduct carbon transferred from CO_2 of flux and of reduction, as above	2.44	1.93
Net carbon to be converted into CO by air	19.67	15.13
Weight of oxygen required $19.67 \times 8 \div 6$ and $15.13 \times 8 \div 6$	26.23	20.17
Weight of nitrogen required $26.23 \times 77 \div 23$, and $20.17 \times 77 \div 23$	87.82	67.52
Total weight of dry air required per ton of pig iron	114.05	87.69
Total heat supplied into furnace by blast, reckoned in cwt. of carbon burnt into CO, each unit of carbon thereby developing 2,473 heat-units, and specific heat of air being 0.239 $114.05 \times 807 \times 0.239$ and $87.67 \times 765 \times 0.239$ 2473 2473	8.89	6.18
If to this heat so measured be added the actual carbon contained in the coke	21.19	17.44
and also the carbon in the flux	1.52	0.22
There is a total of carbon to be accounted for as supplied into the furnace, both directly as carbon and in its equivalent of heat carried in by the hot blast, amounting per ton of pig iron to	31.60	24.14

* See footnote on previous page.

Total carbon to be accounted for as received	31.60	24.14
Consumption of calcined ironstone per ton of pig iron	Cwt. 50.13	50.00
Make of pig iron per month	Ton 2,141	2,453
Quality of pig iron	No. 3.25	3.31
Blast, pressure per square inch at tuyeres	Lb. 3.87	3.73
Area of tuyeres	Sq. in. 142	142

It will be seen that when working on lime, with even an imperfect calculation of the flux, an economy was obtained of $24.19 - 17.44 = 3.75$ cwt. of carbon; whereas the theoretical saving should have been only 2.94 cwt. of carbon, according to the weight of carbon in the carbonic acid displaced from the flux, namely $(1.52 - 0.22 = 1.30) \times 1.26 \div 1.30 = 2.94$.

The calculation which needs explanation in Table I. is the one whereby, from an analysis of the gases and from a knowledge of the carbon consumed per ton of pig iron and of the unexpelled carbonic acid in the flux, it is possible to arrive at the exact mischief done in the red-hot coke region by each of the two sources of that mischief, namely, the carbonic acid of reduction and the carbonic acid from the flux. In his last paper read before this Institution in January 1883, the author showed how this could be accomplished by a laborious method of calculation and by special tables; but continued study has enabled him to simplify the calculation, and by a simple algebraical formula to test the effective working of a blast-furnace by accounting in the form of an expenditure column for every unit of carbon consumed, whether in the heating of the blast or in the carbon burnt within the furnace. His own practice is to account in this expenditure for all fuel by reducing it to units of carbon burnt to carbonic oxide, each unit thereby developing $2,473$ centigrade units of heat. In this way he hopes to have made a complicated problem clear.

Taking the ratio 0.473 determined by analysis as that of carbonic acid to carbonic oxide in the escaping gases when working on limestone, we begin by ascertaining what this ratio should have been, had there been no reconversion whatever of carbonic acid into carbonic oxide. Then would the furnace have worked perfectly, and the ratio would have been found as follows. The net carbon available for producing joint carbonic acid and carbonic oxide has been found in the foregoing statement to be 22.11 cwt. per ton of pig iron. In perfect work all carbonic acid should pass away as such; and the total quantity produced in the furnace will be that from the 6.04 cwt. of carbon for the reduction of the ironstone and that from the 1.52 cwt. of carbon in the flux, namely:—

	Cwt.
Carbon for reduction $\dots 6.04 \times 22 \div 6 =$	22.15 of carbonic acid.
Carbon of flux $\dots\dots\dots 1.52 \times 22 \div 6 =$	5.57 of carbonic acid.
Total carbon $\dots\dots\dots 7.56 \times 22 \div 6 =$	27.72 of carbonic acid.

If these 7.56 cwt. of carbon all appeared in the escaping gases, the balance should pass away as carbonic oxide, namely $22.11 - 7.56 = 14.55 \times 14 \div 6 = 33.95$ cwt. of carbonic oxide. Therefore the perfect ratio of carbonic acid to carbonic oxide would be $27.72 \div 33.95 = 0.816$; but the actual ratio determined by analysis was only 0.473 , and has been lowered from the perfect to the actual by the transfer of a certain amount of carbon from the condition of carbonic acid to that of carbonic oxide. Let x be the weight of the carbon so changed; then from the total carbonic acid possible in perfect work there will have been subtracted $\frac{22}{6}x$, and to the total carbonic oxide possible in perfect work there will have been added $\frac{14}{6}x$. Hence the new ratio of carbonic acid to carbonic oxide will be $(27.72 - \frac{22}{6}x) \div (33.95 + \frac{14}{6}x) = 0.473$. Whence $x = 2.44$ cwt., as taken in the foregoing Table I. for the quantity of carbon transferred from the condition of carbonic acid to that of carbonic oxide per ton of pig iron.

In like manner where lime was employed, containing 0.22 cwt. of carbon as carbonic acid unexpelled, the perfect ratio of carbonic acid to carbonic oxide would have been $22.96 \div 25.20 = 0.911$; whereas in actual work it fell to 0.535 , showing that the carbon transferred from the condition of carbonic acid to that of carbonic oxide amounted to 1.93 cwt. per ton of pig iron.

It is most important to notice the sources of these two different transfers. Obviously it might fairly be supposed that there should have been a difference between them of $1.52 - 0.22 = 1.30$ cwt.; so that the transfer of 2.44 cwt. in the limestone furnace should have been lowered to 1.14 cwt. in the lime furnace; whereas it appears at 1.93 cwt. Let us therefore examine how the 2.44 and

1.93 are made up in the respective cases of working with limestone and with lime.

	Limestone.	Lime.
Carbon transferred from carbonic acid of flux $\dots\dots\dots$	1.52	0.22
Carbon transferred from carbonic acid of reduction by reason of its evolution in region of red-hot coke $\dots\dots\dots$	0.22	1.71
	2.44	1.93

The use of lime has therefore failed to accomplish some of the benefit which the author ventured to hope and predict in January 1883; thus showing that its employment is not an unmixed good. For through a combination of causes the reduction of ironstone when working with lime as flux has been less effective to the extent of $1.71 - 0.22 = 0.79$ cwt. of carbon per ton of pig iron, equivalent in the present comparison to a loss of $0.79 \times 1.26 \div 0.9 = 1.79$ cwt. of carbon per ton of pig iron. To make this point clearer, in the case of working on limestone the proportion of ironstone reduced in the cooler regions of the furnace out of contact with red-hot coke was $50.13 \times 5.12 \div 6.04 = 42.49$ cwt. per ton of pig iron; whilst there passed down into the red-hot zone for reduction there $50.13 \times 0.22 \div 6.04 = 7.64$ cwt. For working on lime the corresponding figures are $50.00 \times 4.33 \div 6.04 = 35.84$ cwt., and $50.00 \times 1.71 \div 6.04 = 14.16$ cwt. In neither of these cases does the dreaded proportion appear of one volume of carbonic acid to two volumes of carbonic oxide; for from the analysis given in Table I. it is seen that the proportion when working on limestone was only $9.25 : 30.89$ or $1 : 3\frac{1}{3}$, and when working on lime $9.79 : 28.95$ or $1 : 3$ nearly. The consideration of these volumetric proportions may therefore be dismissed as inoperative in the present instances.

What then are the causes of the diminution in the weight of carbonic acid of reduction—that is, of the increase in the weight of carbon transferred from the carbonic acid of reduction into the condition of carbonic oxide—despite the removal of 85 per cent. of the carbonic acid from the lime used as flux? The causes of this disappointment when working on lime are twofold:—

Firstly, as intimated at the outset (page 890), when limestone is used, all or nearly all the carbonic acid it contains is necessarily converted into carbonic oxide, thus increasing and prolonging the activity of the reducing zone in a cooler region, while at the same time this cooler region is extended downwards by the absorption of the heat due to the unburning of the carbonic acid to carbonic oxide; thus protracting or prolonging the period of reduction of the ironstone within the extended reducing region; so that the employment of limestone is not an unmixed evil.

Secondly, when lime is used, the weight of carbonic oxide is comparatively diminished, the cool reducing zone is curtailed in its depth, and the total volume of gases is greatly diminished, by reason of the greatly diminished consumption of fuel in the furnace, due to the very economy secured by the expulsion of carbonic acid from the flux. When working on lime, the ironstone undergoing the process of reduction is thus subjected both to the passage of a smaller quantity of reducing gas over it, and to that passage during a shorter period of time before entering the red-hot zone, which zone by the use of lime has been raised somewhat higher in the furnace.

To reduce the above conditions to actual figures, we have when working on limestone, according to Table II., a weight of 116.23 cwt. of gas per ton of pig iron, which are passing over the materials entering the furnace, and of which 39.64 cwt. consist of carbonic oxide, or 27 per cent. of the total. When working on lime, we have only 113.10 cwt. of gas per ton of pig iron passing over the ironstone as it enters the furnace, of which only 29.70 cwt. are carbonic oxide, or 26 per cent. of the total. It will thus be seen that there is only a trifling difference in the percentage of carbonic oxide in the total gases as they leave the furnace; so that, in explanation of the diminished reduction of ironstone in the cooler reducing regions of the

furnace when working on lime, there remains the important fact that the materials from which a ton of iron is produced are exposed to the influence of only 29.70 cwt. of carbonic oxide when lime is employed as flux, instead of to that of 39.64 cwt. when limestone is employed; a proportion of about 3 to 4, or 25 per cent. less carbonic oxide when working on lime.

But whilst disappointment has to be confessed to the extent indicated, there are one or two conclusions to be drawn from the above comparisons, which will well reward further consideration.

The air required for consuming the coke per ton of pig iron is seen from Table I. to have been in the case of limestone 114.05 cwt., and with lime only 87.69 cwt., showing a direct economy of 26.36 cwt. of air, or 23 per cent.; whilst with the same pressure of blast and the same tuyere area the furnace when working on lime turned out 2,453 tons of iron per month against 2,141 tons per month when working on limestone (Table II.). It is in consequence of this increase in the output that the item of sundries in the statement of expenditure of fuel (Table II.) has been reduced from 3.78 with limestone to 3.30 with lime. It is not generally known how far the constancy of the loss by radiation and by tuyere-water, &c., affects the consumption of fuel by reason of increased output; within certain limits this explains the fact that extra driving may be and is accompanied by reductions of fuel consumed to make a ton of iron.

Before passing away from the subject of the smaller quantity of air required to make a ton of iron when lime is employed as flux, it will be proper here to refer to M. Grüner's claim that he was the first to show how, from a knowledge of the quantity of coke consumed and the ratio of carbonic acid to carbonic oxide, the weight of air needed could be accurately ascertained. This in itself was a great stride towards the correct understanding of the phenomena of blast-furnace practice; and the writer has never seen his claim challenged. That method is absolutely correct, and must in any future calculations supersede all other rough and ready methods hitherto in vogue for determining the quantity of air needed.

Attention may here be drawn to two errors into which the author fell in the comparative results given in his paper in 1883. Firstly, he omitted to allow for the carbon needed to melt the ton of pig iron on which the calculations were based, and was under a misapprehension at the time that it was included elsewhere. Secondly, he also assumed that the total loss of carbon in the transfer of a unit of carbon from the condition of carbonic acid to that of carbonic oxide was 3.26 times the amount of that unit; whereas it should have been 2.26 times; namely, 1 unit absorbed by the carbonic acid in the red-hot region, and 1.26 unit needed to be burnt into carbonic oxide at the tuyeres in order to meet the cooling effect of that absorption. In the present comparison of limestone and lime an allowance of 0.90 cwt. has been made for melting the 20 cwt. of pig iron, notwithstanding that M. Grüner adopts Sir Lowthian Bell's figure of 330 calories, which is equivalent to $330 \times 20 \div 2,473 = 2.67$ cwt. of carbon burnt to carbonic oxide for melting a ton of pig iron, whereas in practice a good cupola can melt a ton of pig iron with from $1\frac{1}{2}$ to $1\frac{3}{4}$ cwt. of coke. The author strongly suspects some error in the determination of heat contained in pig iron running from a blast-furnace or cupola, and is glad to learn that M. Grüner investigated the matter further after accepting Sir L. Bell's suggested average of 330 calories. In an admirable pamphlet by M. J. Wolters, written in 1876, on the lines of M. Grüner's work, and called "Etudes sur la fabrication de la fonte blanche pour fort au moyen des minettes ou minerais oolithiques du Luxembourg," he refers to M. Grüner's researches on the fusion of white iron, and gives the reduced figure of 265 calories, equivalent to 2.14 cwt. of carbon per ton of pig iron; but according to actual cupola practice this is still far too high, and the author has always pictured to himself that the blast-furnace must necessarily surpass the average cupola in economy of melting iron, so that he trusts the figure he has adopted of 0.90 cwt. of carbon burnt to carbonic oxide per ton of pig iron will not be found far from the truth.

Method of Treating Gold Ore at Deloro, Canada. J. E. Rothwell. Rep. of the State Mineralogist, California, 1888, through Abstr. Papers Inst. Civil Eng. 48, iv. 69.

At Deloro the ore treated is an arsenical iron sulphide in a gangue of quartz and calcite. It contains about 42 per cent. of arsenic, 20 per cent. of sulphur, and 38 per cent. of iron. On arriving at the mill the ore is crushed in rock breakers and Cornish rolls; it is then sized and concentrated in jigging machines. The concentrates are roasted in two large Howell-White revolving cylinders. In the first a preliminary roasting is carried on, and in the second the ore is roasted sweet. The ore falls from the lower end of the second cylinder, and, when cool, is sent to the chlorinators. These are cylinders of $\frac{3}{4}$ -inch boiler iron, lined with 20-lb. sheet-lead. The truck from the cooling floor is raised to a platform over the chlorinators, and the charge of chloride of lime is placed on the top of the ore. Water is measured into the cylinder first, the proportion being 120 gallons to the ton of ore, and then the contents of the truck are let in; sulphuric acid is then poured in through a funnel, the cover fastened on, and the cylinder started revolving. After from one and a half hour to three hours the excess of gas is drawn off, and an exhaust pump attached to produce a partial vacuum. In this way most of the free gas is removed. The cover of the discharge aperture is rapidly removed, and the charge emptied on to a sand filter in a tank with a tight-fitting cover and exhaust pipe. A better method is to wash the charge in the chlorinator until the liquor decanted into settling tanks shows no sign of gold. A charge of three tons may in this way be washed in two to three hours, while a 1-ton charge on a sand filter requires six to eight hours. From the settling-tanks and filters the clear solution is run into precipitating tanks, where it is treated with sulphuretted hydrogen, generated from equal parts of paraffin and sulphur in a small cylinder of heavy boiler-iron. The gas first passes into a receiving-tank to collect the volatile oils; thence it is forced through the solution to be precipitated. When the precipitation is complete the tank is allowed to stand for a short time, and then the solution is allowed to flow through pressure-filters. Three of these small filters will empty a 1,500-gallon tank in three to four hours, and leave it ready for another precipitation, or the precipitate can be collected in another filter-press, pressed into cakes, dried, roasted, and melted with borax. By means of this process 96.16 per cent. of the gold in the ore is extracted.

The Development and Present Condition of Puddling in Gas Furnaces. E. Goedicke. Stahl und Eisen, 1889, 554, through Abstr. Papers Inst. Civil Eng. 48, iv. 73.

THE regenerative gas furnace has of late years been very successfully adapted to puddling in the ironworks of the Austrian Alps. After discussing the earlier forms of furnace, including those of Siemens, Borbely, and Prie, the author proceeds to describe that of Springer, which is now largely used. This furnace, introduced in 1883 at Völklingen on the Saar, is a large Siemens furnace, having its regenerators built in two square blocks above the ground-level, and two double puddling-furnace beds placed between. These beds are about 6 ft. 4 in. broad, and 6 ft. 2 in. long, and are only separated by a narrow throat-flue of the breadth of the iron framing of the bed. Each takes a charge of $10\frac{1}{2}$ cwt., and they are worked alternately, the flame passing first over the bed in use, then over the second, which contains the materials of the next charge, and finally through the regenerators on the chimney side. When the charged is finished and the balls have been removed for shingling, that in the second bed is already melted, so that on the reversal of the flame, the boiling period commences at once. In this way a very large production is realised; from 6.2 tons to 7 tons of best, and as much as $8\frac{2}{3}$ tons of common iron, being obtained in the turn of 12 hours, the number of heats varying from 13 to 15 in the former, to 16 to 18 in the latter case. The loss experienced is 1.5 to 2 per cent. on the weight of the charge in the best work, but may be as much as 5 per cent. when the furnace is driven hard. The consumption of fuel varies with the

quality, being from 45 to 50 per cent. for the best large coal, 57 to 65 per cent. for small slack, and 60 to 70 with lignite. In addition to this, from 20 to 25 per cent. is required for raising steam, as the stack boilers of the old puddling furnaces are of course done away with.

The form of construction described above, with regenerators above ground, although advantageous in many ways, and more particularly in allowing the regenerators to be easily opened for cleaning, has the defect of requiring a very long gas-passage between the top of the regenerator and the point of combustion, and, therefore, in the newer furnaces, the regenerators are placed underground and at right angles to the furnace proper, an air space being interposed between the roof and the ground, to prevent excessive heat by radiation. By this arrangement the length of the furnace is reduced from 42 ft. to 29 ft. The tops of the air and gas ports and the beds are covered with strongly curved roofs, making capacious combustion chambers. The cast-iron frame-plates are protected by layers of magnesite bricks, which are also used to bring the bridges to the proper height. These latter require renewal after two or three turns. The regenerators require cleansing at intervals of 12 to 15 weeks; they are filled with bricks measuring 12 by 6 by 3 in. (Austrian). One-third of the filling is in Dinas bricks, a second third in ordinary clay fire-bricks, and the last third is common building bricks. When the heating is done with large coal, two slack producers, with a total grate surface of 2·6 square metres, and capable of gasifying 3 tons of fuel in 21 hours are required; but with small slack, four step-grate producers, 4 square metres of surface are necessary, the consumption being increased to 76 cwt. In the former case the grates require to be thoroughly cleaned at intervals of eight hours, but with the step grates and dirtier fuel, one producer must be cleaned every two hours. This is done during the balling period, when the demand for gas is less than at other times, and the furnace is at its hottest. When puddling white charcoal iron and a proportion of greyer coke-melted metal, about 14 heats of about 10·4 cwt. are obtained in 12 hours, from 2 to 3 cwt. of cinder being required for fettling. The rabbling of the charge lasts from 20 to 25 minutes, making up the balls 15 minutes, and their removal 10 minutes, giving a total time of about 50 minutes for the heat. At this rate there is time for 14 heats with 20 minutes to spare in the turn of 12 hours. These figures refer to pig iron free from phosphorus. At the Hermannshütte in Bohemia, where the metal contains 1·7 per cent. of phosphorus, only 10 to 12 heats can be got in the turn of the iron if it is to be properly purified.

From the rapid nature of the work in these furnaces, it has been found better to reduce the turn from 12 to 8 hours, so as to give the puddler 16 hours rest out of the 24. In this way at one work a notable increase in yield and economy of material has been obtained, taking the average output of the year 1887.

FURNACE WITH SLACK PRODUCER.

	Twelve Hours.	Eight Hours.
	Tons.	Tons.
Yield per ton	6·77	7·21
Charge per cent.	102·24	101·20
Coal per cent.	69·20	37·70

FURNACE WITH LARGE COAL PRODUCER.

	Twelve Hours.	Eight Hours.
	Tons.	Tons.
Yield per turn	7·06	7·90
Charge per cent.	102·04	101·20
Coal per cent.	47·00	42·00

Another system of furnace described by the author is that of Jullich, which is used at some works in Bohemia, consuming brown coal from Dux. This is essentially a combination of two large puddling furnaces placed side by side with a dividing wall between them, having a system of regenerators common to both. The flame is divided over the two beds which are heated simultaneously, and mites to pass through the regenerators on the chimney side. The charge is worked on one bed, while that on the other is being melted down, and as soon as the first is finished, the workmen go over to the opposite side when the second charge is ready for boiling. This furnace combines many of the advantages of that of Springer, but is rather more extravagant in fuel. The average results obtained with 9 cwt. charges were 13½ heats in 5·81 tons in 12 hours, with 103·4 per cent. of pig iron and 59·2 per cent. of coal.

The last furnace described is that of Pietzka, which has been introduced at Witkowitz in Bohemia, and Schweschat in Austria. This has two beds like that of Springer, but is not regenerative, being heated by a grate fire with forced draught and heated air, while the exhaust flame passes round a stack boiler in the ordinary way. The bottom plates of the furnace are carried upon longitudinal girders, which are supported by a central ram placed below, so that the whole working part of both beds between the fire and flue bridges can be lowered clear of the roof and turned half round in the horizontal plane. In this way the first charge on the bed at the flue end, which has been melting down during the puddling of that at the fire-place end, is brought into the working position as soon as the latter is finished. With 10 and 11 cwt. charges 6·1 tons were obtained per turn at Witkowitz, and 6·4 tons at Schweschat for 106·6 per cent. of metal and 66·5 per cent. of coal at the former, and 105·4 per cent. and 55·8 per cent. at the latter place. In August 1887, the consumption of coal was as low as 48·9 per cent., which the author considers to be the most economical results yet attained in a grate-fired puddling furnace, as about one-half of that quantity, 27 per cent., was consumed in raising steam, leaving only 28·84 per cent. for the work of puddling proper.

Barrel Chlorination. A Thies, Rep. of the State Mineralogist, California, 1888. Sacramento, 1889, 844, through Abstr. Papers Inst. Civil Eng. 48, iv. 77.

THE author describes the method of barrel chlorination as conducted at the Phoenix mines, North Carolina, and the Haile gold mine, South Carolina. After working for two years with the original Mears process, he found that the results were quite as good without pressure, as with the highest pressure. He has, therefore, remodelled the chlorinator by closing up the hollow trunnion, removing the goose-neck and acid chamber, and substituting a lead valve, connected with the inner lead lining, in such a way that the pressure of free chlorine can be ascertained at any moment. The capacity of the chlorinator is from 1 to 1½ ton of roasted ore. For the Phoenix ores, 40 lb. of chloride of lime, and 50 lb. of commercial sulphuric acid are used per ton of roasted ore. It is found best, however, to add half this charge first, to rotate for three or four hours, and then to add the other half. The Phoenix ore contains a considerable quantity of copper pyrites. At the Haile mine, where the ore is a pure iron sulphide, there are used but 10 lb. of chloride of lime to 15 lb. of acid, and 4 tons of roasted ore are treated in two chlorinators during 10 hours. With the barrel process, 94 per cent. of the assay value of the ore is extracted. The cost of chlorination by this process depends on the number of tons treated per day. Two men can easily treat 4 tons in 10 hours, the cost being as follows:—

	£ s. d.
40 lb. chloride of lime	0 4 10
60 lb. sulphuric acid	0 4 10
Two labourers	0 7 4
One chlorinator	0 8 0
Motive power	0 2 0
Total	1 7 0

or 6s. 9d. per ton. Adding to this 5d. for sulphuric acid for making ferrous sulphate, and 10d. for repairs and wear, gives the sum of 8s. per ton for chlorination, or 18s. 7d. for roasting and chlorinising 1 ton of roasted ore, representing $1\frac{1}{2}$ ton of raw iron pyrites. In less than seven hours from the time the ore is in the chlorinator, the solutions are ready for precipitation and the tailings clean. The wear on the inner lead lining of the chlorinators is inappreciable. Indeed, a chlorinator in use at the Phoenix mine for five years shows no sign of wear.

Supply and Use of Nickel and its Alloys with Steel. Eng. and Min. Journal, 48, 336.

THE most interesting paper and the most instructive excursion of the recent meeting of the American Institute of Mining Engineers at Ottawa related to the Sudbury, Ontario, copper-nickel deposits. The paper was read by Dr. E. D. Peters, manager of the Canadian Copper Company at Sudbury, and it covered an exhaustive description of the deposits, which were originally thought to be of such importance as a source of copper supply that apprehension was felt in some quarters that they would affect the price of the metal. Such, so far at least, has not been the case, though the workings have proved immense bodies of nickel-bearing pyrrhotite, with occasional pockets of copper pyrites. In places this bed has been proved to be 100 feet thick, and its limits have not yet been ascertained. The three mines in the district belonging to the Canadian Copper Company are not uniform in character, and vary considerably in the amount of nickel contained in the ore. The Stobie mine, which possesses the largest bodies of ore, and is worked by open cast, as much as 500 tons being thrown down by one blast recently, is low in nickel, but is valuable from its iron contents, after roasting, as a flux for the ores containing a higher percentage of nickel and copper, but more mixed with gangue.

Mining on this system means cheap production, and we can quite believe that Dr. Peters is correct in his estimate that he can produce from this mine 80 tons a day, at 30 to 35 cents a ton. In the Copper Cliff mine the ore occurs in irregular masses, but is very rich in nickel, and large bodies are developed, carrying from 8 to 10 per cent. in that metal. The Evans mine also has a large body of pyrrhotite, but is more highly nickeliferous than the Stobie. This mine produces about 60 tons of first-class ore a day.

The roasting and smelting arrangements, as might be expected under Dr. Peters' management, are models of ingenuity and efficiency, and the result is that about 40 tons of matte are produced a day, averaging about 27 per cent. of copper and 15 to 18 per cent. of nickel. The furnace work is worth recording, one smelter averaging for months of continuous work 125 tons of ore for 24 hours, and having gone as high as 156 tons. Fuel seems to be the only disadvantage, Connellsville coke being used at the somewhat high cost of about 7.25 dols. a ton, but against this is to be set the judicious handling of the ore and its fluxing qualities, which enables the fuel to carry a burden of 8 to 1.

The result of these operations at Sudbury will be an enormous increase in the world's supply of nickel. The supply hitherto has been principally from the mines of the French company in New Caledonia, and this supply has been regulated to a great extent by the demand, at about 1,000 tons a year, maintaining the price at what the company considered a profitable basis, or rather as high a figure as it could without decreasing consumption, for it has never shown very great profits. The Sudbury production already exceeds the world's consumption, and Dr. Peters has no doubt that he can produce 2,000 tons of nickel a year.

The important question is, will there be a market for this increased supply of the metal even at considerably lower prices than those at present ruling? Mr. James Riley, in a paper before the Iron and Steel Institute on tests made by him of alloys of nickel and steel, furnishes data which convince him that there will be such a market (see this Journal, 1889, 547). It appears that in France a patent has been taken out for these alloys, and Mr. Riley visited the works

at which the process was carried on, and continued his tests at his own works in Scotland with most remarkable and satisfactory results. His data, as usual, are clear, and the results are conclusive, although, as he says himself, several series of tests, involving a very large number of separate experiments, are necessary to a full investigation. We have not space to give in detail here the actual tests carried out, but some of the conclusions arrived at will be sufficient for our steel makers to appreciate the importance of the subject.

The alloy can be made in any good open-hearth furnace working at a fairly good heat. The charge can be made in as short a time as an ordinary "scrap" charge of steel, say about seven hours. Its working demands no extraordinary care, in fact not so much as is required in working many other kinds of charges, the composition being easily and definitely controlled. If the charge is properly worked nearly all the nickel will be found in the steel—almost none is lost in the slag, in this respect being widely different from charges of chrome steel. Any scrap produced in the subsequent operations of hammering, rolling, shearing, &c. can be remelted in making another charge without loss of nickel.

The addition of 4.7 per cent. of nickel raises the elastic limit from 16 up to 28 tons, and breaking strain from 30 up to 40 tons per square inch, without impairing the elongation or contraction of area to any noticeable extent. With only 3 per cent. of nickel somewhat similar results are found, combined with an increase in the carbon to 0.35 per cent.

The hardness increases as the nickel is increased, until about 20 per cent. is reached, when a change takes place, and successive additions of nickel tend to make the steel softer and more ductile. In the hardening and tempering tests Riley shows the possibility of very largely raising the strength and elastic limit, and the hardness of these alloys, but he is not yet prepared, from lack of time, to say to what extent. He has, however, gone up to 95.6 tons breaking strain and 54 tons elastic limit. With regard to torsion tests, it is not necessary to have a steel high in nickel, as those containing only 1 per cent. gave the best results.

In the very important matter of corrodibility, the steels rich in nickel are practically non-corrodible, and those poor in nickel are much better than other steels. The theory of the inventors, from which many metallurgists dissent, is that steel is composed of crystals of metallic iron, cemented together by carbide of iron, and the extra strength given is by the nickel alloying with this carbide of iron to form a stronger "cement," that the space between the crystals of iron is thus more completely filled, and the cohesion between them rendered much more powerful.

The applications and uses of such an alloy are boundless. Its vast increase of strength and elasticity over ordinary steel, its non-corrodibility and hardness alone, open up for it a field in engineering that will render possible what was previously nearly impossible from the masses requisite to attain the object. For example, it seems to bring quite within the bounds of practicability a cantilever bridge over the North River between New York and Jersey City that shall excel even the Forth bridge, with its 1,710 ft. spans and 150 ft. elevation, as a work of engineering skill and beauty. It is only necessary to remember the difference between 30 tons and 95 tons breaking strain, and 17 tons and 54 tons elastic limit.

Some Notes on the Rarer Elements found in the Leadville Sulphurets. F. L. Bartlett. Eng. and Min. Journal, 48, 342.

IN working some low grade sulphurets from the Iron Silver mine, of Leadville, by my new process for the manufacture of pigments, I have made a peculiar discovery, which I believe will interest many. By my process I have been able to eliminate the following list of the rarer elements:—Selenium, cadmium, thallium, gallium, and, possibly, indium and some others. In addition to these, and in connexion with them, I also find mercury, antimony, arsenic, and one unknown substance. It seems to me that the finding of mercury in these ores is new, at least I am not aware that this metal has ever before been found in the Leadville ores.

In order to make the matter plain, it becomes necessary to explain the method of extraction. This, as will be seen, is quite different from anything before attempted. The ores in question were the heavy zinc sulphurets, containing some 35 per cent. of zinc, 6 per cent. of lead, with very little rock. The novelty of the method consists in treating the ores, without previous roasting, to a partial distillation, the fume coming off being cooled and collected in cloth bags. This fume is mostly zinc and lead, but, as can be easily understood, contains many other elements, in fact, must contain about all the volatile matter in the ore, whatever its nature. It will be also understood, that not having been previously roasted, the fume must contain any mercury that may have been in the ore, however slight in quantity, also that the rarer elements closely allied to sulphur will be there. The fume thus collected is subjected to a refining process, which further condenses the rare elements. This refining process consists in subjecting the fume to a red heat in closed tubes, the fume being constantly stirred while under the influence of the heat, the object being to drive off any and all of the lighter elements as sulphur, arsenic, antimony, &c., which might interfere with the colour and quality of the pigment. It follows that if the fume from this last operation be condensed and collected, that this will be the double refined essence of the light volatile elements contained in the original ore.

The amount obtained from a ton of ore in this condensed form is, of course, very small, being, I should say, not more than 2 lb. This condensed material is a mixture of various colours, but when well mixed takes a dull red colour. It has an acid reaction from the presence of sulphuric acid, and has a garlicky odour.

It dissolves in boiling nitric acid, leaving a residue of lead sulphate, and a gummy substance of a peculiar nature which I have not yet been able to determine. This gum does not appear to have come from the fuel used in the original ore treatment; in fact, it is wholly unlike tarry matter, and is incombustible—that is, will not burn—but can be volatilised at a high heat. I have not had time as yet to determine if it is an organic substance or not; of course it is possible that it comes from the fuel. In separating the elements previously mentioned, I have followed the methods outlined by Fresenius. Selenium, cadmium, thallium, mercury, and arsenic are quickly and easily obtained. Indium, as before stated, I am not sure about, and my tests on gallium have not been all that I could desire; still I am quite sure that they are there.

In addition to these elements enumerated, there are certainly others which I am not able to determine, and in working the stuff one is constantly getting precipitates where not expected.

The amount of mercury in the fume varies; it runs from 2 to 10 per cent. The cadmium also varies a good deal, as does the other elements, depending on the manner in which the fume has been collected. All the fume contains more or less zinc and lead, and sometimes free sulphur.

To say the least, this material is an interesting compound, and to anyone who has the time it will well repay one for working upon it.

The writer hopes to be able to make this material a source of extraction, in some quantity, of the elements selenium and cadmium, possibly some others.

In regard to the presence of mercury, I would say that no fuel or other ore has been used with the Leadville ore from which the mercury could by any possibility have come. As a matter of fact, the ore was worked alone, and the fuel was the same as was used before any mercury was found, thus proving that it must have come from the Leadville ore alone.

The writer will be glad to send samples of this compound to anyone having a desire to make an analysis of it. As an assistance to its determination, I will say that the following elements will be sure to be found. How many others may be present I will not attempt to say. Zinc oxide, sulphide, sulphate, and sulphite, lead sulphate, lead sulphide, free sulphur and sulphuric acid (usually), cadmium, selenium, thallium, indium (?), gallium, arsenic, antimony, carbon, and mercury.

PATENTS.

The Production of Alloys of Copper with Iron or Steel and another Metal. L. Q. Brin, Paris, France. Eng. Pat. 13,881, September 6, 1888. 6d.

ALUMINUM iron is melted and to it is added, in any desired proportion, copper or aluminium bronze, for the production of the triple alloy. To avoid loss of metal by oxidation it is desirable to perform the operation in an atmosphere of aluminium chloride, or to use a mixture yielding the same.—A. W.

Process for Alloying Iron and Steel directly with Aluminium in the Blast Furnace. L. Q. Brin, Paris, France. Eng. Pat. 14,287, October 4, 1888. 6d.

THIS is a claim for the direct production of aluminium cast iron by charging layers of a mixture of an aluminous compound and salt, into the blast furnace in which the ordinary process of iron extraction is taking place. The patentee's method of charging the blast furnace is illustrated by a drawing.—A. W.

Improvements in and relating to the Manufacture of Lead from its Ores and Compounds. C. H. T. Havemann, Paris, France. Eng. Pat. 14,331, October 5, 1888. 6d. (Compare this Journal 1889, 197.)

THE patent is based on the fact that lead sulphide is reduced to the metallic state by fusion with caustic soda or sodium carbonate. The former is preferable because a portion of the sulphur is said to be expelled as H_2S instead of forming sodium sulphide, and thus less alkali is required; moreover, the use of sodium carbonate causes the formation of a "double compound of lead and sodium" unless about 10 per cent. of iron be added.

The process is carried out by fusing the lead ore (e.g., galena) with about 25 per cent. of caustic soda, and running off the lead and slag in the ordinary way; the latter is then regenerated by treatment with water and carbonic anhydride or sodium bicarbonate, thereby forming normal sodium carbonate and sulphuretted hydrogen; the liquor is then causticised and run directly on to a fresh charge of ore.

It is claimed that a quantity of lead equal to the assay value of the ore (i.e., about 6 per cent. more than is got by the methods at present used) is obtained.—B. B.

Improvements in Furnaces and Apparatus for Heating Pots and Crucibles. W. G. Foster, Streatham Common. Eng. Pat. 14,391, October 6, 1888. 8d.

See under VII., page 884.

Method of Plating Metals with Aluminium and other Metals, such as Platinum, Gold, and Silver. L. Q. Brin, Paris, France, and A. Brin, London. Eng. Pat. 15,506, October 29, 1888. 4d.

THE metal to be coated is covered with a paste of an aluminium-yielding flux consisting of clay, salt, fluorspar and borax, and is dried in a kiln (this Journal, 1889, 199, 399, and 548). It is then heated to a higher temperature to reduce the flux and melt the plating metal. If the flux does not contain the plating metal, the latter, as a fine dust, is sprinkled over the heated flux-coated metal and the whole is re-fired. Thus the object alloys superficially with the aluminium, and the coating metal is flashed over the alloy so produced.

—A. W.

Improved Methods to alloy Metallic Aluminium with any other Metal. L. Q. Brin, Paris, France, and A. Brin, London. Eng. Pat. 15,507, October 29, 1888. 4d.

THE metal to be alloyed with the aluminium is melted with the aluminium-yielding flux of the previous patent, and metallic aluminium in small pieces coated with the same flux

is added. By this method of procedure it is maintained that an alloy is produced "which is perfectly homogeneous and free from inequality of mixture due to difference of specific gravity," and that loss of aluminium by vaporisation is avoided.—A. W.

Improvements in the Manufacture or Production of Silicium Copper. W. Feld and G. von Knorre, Charlottenburg, Germany. Eng. Pat. 15,572, October 29, 1888. 6d.

COPPER, or its equivalent of oxide, is heated with fossil meal and a substance capable of yielding chlorine or fluorine, whereby chloride or fluoride of silicon is produced, and is acted on by the copper with the production of silicium copper and free chlorine. 150 parts of copper, 50 parts of fossil meal, and 30 parts of salt are made into a paste with tar. The mixture is made into cakes, carbonised by heating to a dull red, and is then smelted with a flux of quartz and lime. Copper containing 8 per cent. of silicon is obtained. Fluorspar may be used instead of the common salt, but is not so advantageous, as the resulting metal contains only 7 per cent. of silicon.—A. W.

Improvements in Preparing Iron and Steel Sheets or Plates previously to Galvanising them (that is, Coating them with Spelter). Davies Bros. and Co., Limited, and E. A. Davies, Wolverhampton. Eng. Pat. 16,489, November 14, 1888. 4d.

IN the ordinary process of galvanising, in which the sheets to be coated are pickled, washed, and passed to the galvanising baths, a comparatively rough coat is obtained, due, in the opinion of the patentees, to the pickling, which acts irregularly on the plates, pitting them to some extent. In order to obviate this it is now proposed to pass the washed plates between cold rolls, run under water or sprinkled by it, by which means irregularities are removed without the plates suffering oxidation. They are then dipped in the ordinary manner. Besides obtaining a smoother surface, a saving of zinc is said to be effected.—B. B.

A Manufacture of Steel alloyed with Copper. H. Schneider, Le Creusot, France. Eng. Pat. 16,569, November 14, 1888. 4d.

THE patentee claims the manufacture of alloys of steel and copper by any method, in any proportions, and containing any quantities of carbon, manganese, and silicon, the alloys being suitable for ordnance armour plates and other military purposes.—A. W.

Improvements in the Manufacture of Iron and Steel, and of Alloys of Iron. W. C. Roberts-Austen, Chilworth, E. J. Ball, and A. Wingham, London. Eng. Pat. 16,671, November 16, 1888. 4d.

THE patentees claim to purify iron, steel, and alloys of iron, particularly from sulphur, by treating the molten metal with a mixture of sodium hydrate or carbonate or lime with any suitable cyanide or ferrocyanide; the lime may be replaced by fluorspar. In the case of pig iron the metal is treated "in a refinery which should be lined with basic material," with a mixture of 5 parts of sodium carbonate, 4 parts of lime, and 1 part of cyanide or ferrocyanide of potassium, in quantity equal to 3–5 times the amount of sulphur to be removed, the fused metal and purifying composition being intimately mixed together.

For steel made by the Bessemer process, the composition is added, together with the ferro-manganese, at the end of the blow after the slag has been poured off, the converter rocked to agitate the charge, and the whole poured in the course of a few minutes. As an incidental advantage, it is claimed that considerably less ferro-manganese than usual is needed. In the open-hearth process the mixture is preferably placed in the ladle and the charge run in upon it, as if added in the furnace the alkaline salts which are volatilised "attack the silica work of the roof and ports."—B. B.

Improvements in Apparatus for the Treatment of Zinc. L. H. Cahaigne, Paris, France. Eng. Pat. 17,324, November 28, 1888. 1s. 3d.

THE apparatus is for purifying zinc by distillation. Four retorts set in two rows, one above the other, are contained in a furnace, and all open into a common condensing chamber. A similar furnace, fitted with the same number of retorts, is placed opposite the first, and its retorts open into the same condenser.

Each retort is provided with a syphon at about the middle point of its height, through which melted zinc can be introduced without permitting access of air, and with a syphon at its lowest part for the withdrawal of non-volatile impurities. The condenser has also a syphon-exit for the distilled metal.

The furnace gases after heating the retorts pass under the condenser in order to keep the zinc in it fused, and their effect may, if necessary, be supplemented by that of gases led direct from the furnace without first passing round the retorts.

In starting the distillation from any given retort, powdered charcoal is first placed in it in order to replace the air by a reducing gas.—B. B.

Improvements in the Treatment of Copper Precipitates. G. Gatheral, Hebburn-on-Tyne. Eng. Pat. 560, January 11, 1889. 4d.

TO purify copper precipitate containing arsenic, it is mixed with a convenient quantity of iron or copper pyrites and calcined in a closed furnace. The arsenic is given off as arsenious acid, which may be condensed. Afterwards the whole is calcined in the open furnace, and the copper extracted by any convenient method.—A. W.

A New or Improved Compound for Use in Welding, Tempering, and otherwise Treating Metals. C. U. Fisher, London. From H. F. Lord, Wyoming, N.J., U.S.A. Eng. Pat. 11,686, July 23, 1889. 4d.

SIXTEEN parts by weight of borax are heated to drive off most of the water of crystallisation, one part of sal-ammoniac, one part of "carbonate of iron," and four parts of plaster of Paris are added, the whole mixed and heated gently "until it is dry." It is then cooled, ground, and packed for sale. It is used for welding steel, and is alleged to restore the good quality of the metal if it has been previously overheated or "burnt." The proportions may be varied.—B. B.

An Improved Process for Treating Iron, Steel, and other Metals, to Prevent Oxidation thereof while in a Heated State. H. H. Lake, London. From G. W. Cummins and J. H. Coleman, New York, U.S.A. Eng. Pat. 13,138, August 20, 1889. 8d.

THE annealing of easily oxidisable metals is usually conducted in air-tight vessels, in spite of which the surface of the articles treated is in some degree acted on by the residual air present. The patentees substitute a reducing or indifferent atmosphere, effecting their purpose in various ways, of which the following is a type:—A cylindrical cast-iron retort is set horizontally in a furnace, raised to incandescence, and filled with coke or charcoal. The products at first evolved (hydrocarbons, water, &c.) are led away to waste, a blast of air is then driven in at one end of the retort, and the gases evolved again run to waste for a short time. When a mixture almost wholly composed of nitrogen, carbon monoxide, and carbon dioxide is being produced, connection with the waste pipe is closed, and the gases led into a worm, where they are cooled, and any water still present condensed. Thence they pass into a drying chamber fitted with shelves laden with fused calcium chloride or pumice soaked in sulphuric acid, and on into the annealing pot. If not immediately required they may be stored in a gas-holder between the worm and the drying-chamber.

A steady stream is maintained through the annealing pot during the whole operation, and the articles, when withdrawn,

are found to be clean and bright and adapted for plating with non-oxidisable metals, or galvanising.

In order that the production of the gas may be continuous, it is found convenient to have two retorts in each furnace, and charge and start one while the other is under blast. The usual composition of the gas employed is nitrogen 68 per cent., carbon monoxide 27—33 per cent., and carbon dioxide from a trace to 4 per cent.—B. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

The Thomson Electric Welding Process. W. C. Fish.
Paper read before the Iron and Steel Institute.

THIS paper contains a summary of the history and technique of the method invented by Professor Elihu Thomson (see this Journal, 1889, 288) for the purpose of joining two pieces of metal by the aid of the heat produced by electricity passing through them. The plant for the purpose comprises (1) apparatus for the production of a suitable current, with means for quickly regulating the current; (2) clamps, which are relatively moveable, for holding the pieces of metal so that the pieces can be pressed together. The clamps are connected with the source of electricity, which may be a secondary battery, a dynamo of extremely low armature resistance, or an alternating-current dynamo provided with a transformer. The last method in practice presents many conveniences over the others. The circuit of the transformer, in which the strong welding current is produced, usually consists of a single turn of thick copper bar. The different fluxes employed are similar to those used in the ordinary methods of welding and brazing. In some cases the pieces are slightly rounded at the ends before welding, in order to increase the localisation of heat, to ensure the thorough fluxing of the metals and the expulsion from the weld when pressure is applied of the impurities due to the flux and other causes. As in the old process, the temperature of the welding heat is of importance. In determining the correct temperature, the operator is aided, in addition to the colour of the metal, by the resistance to compression which the pieces exert when the clamps are forced together. The pressure applied generally produces at the weld an enlargement. This can, in some cases, be reduced whilst the metal is still hot, by hammering. Judicious hammering at the weld, particularly with the harder grades of cast steel, is often advantageous, on account of its refining tendency. In welding copper and brass, where there is but a limited range of temperature within which the welds can be made, the necessary pressure can be produced by an adjustable spring, and when the proper temperature is reached, the current can be automatically switched off. As to the tensile strength of welds, the following figures are quoted:—

Materials.	Breaking Strength in Lbs. per Square Inch.	Position of Fracture.
Wrought iron.....	53,119	1·7 in. from weld.
Cast steel.....	81,000	At weld.
Bessemer steel.....	50,584	"
Copper (hard drawn)	31,530	"
" "	32,480	½ in. from weld.
Brass	40,820	At weld.
"	47,730	½ in. from weld.
Steel and German silver....	49,410	At weld.
Cast steel and wrought iron	52,139	3 in. from weld.
Brass and wrought iron....	33,550	At weld.

Speaking generally, the tensile strength at the weld is 90 per cent. of the unwelded metal. Only an approximate estimate is furnished of the energy spent in making the welds. In the case of iron and steel, the data shown below is given:—

Ampères per Square Inch required.	Time of Weld.	Product.
3,500	40 seconds	380,000
12,000	30 "	360,000
15,000	20 "	300,000

In the last case, the actual power applied at the belt of the dynamo was calculated as about 27 horse-power, the power required for the bar itself (which was of iron one-half inch in diameter) being 5·36 horse-power. There is no danger to the operator, who need not have special electrical knowledge. The advantages claimed for the process are:—(1.) The possibility of welding precious metals and alloys without introducing impurities. (2.) Economy, rapidity of work and convenience and cleanliness compared with the forge fire. (3.) The ease with which irregular shapes can be welded. (4.) The localisation of heat to the weld. Amongst the numerous miscellaneous applications of the process may be named: (1), the welding of wire in the construction of long lengths; (2), the welding of wire ropes and cables; (3), the welding of tires, hoops, bands, and similar endless work, especially links; (4), manufacture of pipes of various metals; (5), general construction and repair work, especially the manufacture of tools where different grades of steel are united; (6), numerous applications in shaping, forging, brazing, local tempering and annealing; (7), finally may be mentioned the possibility of electric riveting. This is accomplished by electrical heating of the rivet when in position to the proper temperature.—W. W. H. G.

Chemistry of Secondary Batteries. E. Frankland. Proc. Roy. Soc. 46, 306.

THE author shows that the processes of charging and discharging a secondary battery consist essentially in the decomposition and formation, respectively, of a sulphate of lead which is not the ordinary white sulphate. By the action of dilute sulphuric acid in excess on litharge and minium respectively (these being the two oxides of lead most frequently used in secondary batteries) he obtains from litharge a buff-coloured salt, according to the equation—

and from minium a brownish-red salt—

He considers that these two coloured salts form the active material of secondary batteries, and gives equations representing the reactions which occur during the charging and recharging of the battery. He points out that only half as much red salt is required on the negative plate as on the positive plate.—W. W. H. G.

An Experimental Theory of Lead Accumulators. G. Roux. L'Électricien, 1889, 411, through Abstr. Papers Inst. Civil Eng. 48, iv, 84.

THE author has endeavoured to determine the true reactions on the positive and negative plates of a lead accumulator, by ascertaining the amount of sulphuric acid absorbed by the plates during discharge, and deducing therefrom the chemical operation involved.

The experiments were made on cells of the Julien type in the following manner:—The negative plate was placed in a porous cell filled with acid of known strength, the positive plate being outside the porous cell also in acid of known strength.

The plates were slowly charged till gas was just disengaged; the acid was now changed, and fresh acid introduced for the discharge, which was continued till the electro-motive force began to fall. The ampère-hours were obtained from the integral curve of current and time. The amount of acid absorbed was then found from the known original volumes and strengths by triturating the resulting liquid with a solution of caustic potash of known strength. The results of a large number of experiments give the following as the weight of normal sulphuric acid absorbed per ampère-hour:—

Negative Plate.	Positive Plate.	Both Plates.
Gm.	Grms.	Grms.
1.410	2.293	3.705

The following equation satisfies these results:—

Before discharge—

After discharge—

The experiments therefore point to a sulphating of both plates during the discharge, with a production of water.

The experiments were conducted during the discharge only, because the acid liberated during the charge, in the substance of the plates, takes a long time to disseminate itself in the liquid, whilst the acid is absorbed from the liquid very readily during the charge. (See preceding abstract and Proc. Roy. Soc. 46, 306.)

Electric Conductivity of Saline Solutions. Reciprocal Displacement of Acids. P. Chrontschoff. *Compt. Rend.* 108, 1100–1102.

FROM the results of these electro-chemical researches as displayed in a table, the author concludes (1) that acetic acid is completely displaced by hydrochloric acid; (2) that tartaric acid, combined with soda, is almost entirely displaced by sulphuric acid; (3) that acetic and tartaric acids divide the base; (4) oxalic acid added to sodium acetate divides the base; (5) with $\text{K}_2\text{SO}_4 + 2 \text{HCl}$ the observed conductivity is near the mean of the formula $\text{H}_2\text{SO}_4 + 2 \text{KCl}$, a result not accordant with existing theories.—J. M. H. M.

The Consumption of Energy in Electro-Metallurgical Processes. H. Pontbrière. *La Lumière Électrique* 33, 1889, 251, through *Abstr. Papers Inst. Civil Eng.* 48, iv, 85.

THE author here draws a comparison between the energy consumed in the following modes of treatment:—(1.) Electrolysis with a soluble anode, represented by the Marchese process at Casarza, near Genoa, and at Pont-Saint-Martin in the Aosta valley. (2.) Electrolysis with an insoluble anode. (3.) Thermo-electrolysis, represented by the extraction of aluminium from the molten fluoride by the Kleiner process at Tyldesley, Lancashire, the Bernard and Minet process at Creil, near Paris, and the extraction of magnesium from its chloride, at Humelington, near Bremen, by the Granelt process. (4.) Electro-thermal treatment, represented by the manufacture of enpro- and ferro-aluminium by the Cowles electric furnace, at Lockport, U.S.A., and at Milton, near Stoke-on-Trent, and also by the Heroult electric crucible at Neuhausen, Switzerland. The author treats the question under three heads:—(a.) Energy consumed, or chemical yield; (b.) yield of the ore; (c.) purity of the metal produced.

(a.) *In process* (1).—Two tons of copper were produced in 24 hours from anodes of copper matte, with a composition, in round numbers, of 55 per cent. copper, 38 per cent. iron, and 27 per cent. sulphur. The work produced by the dynamo was 1,963,600 watt-seconds = 1,860 units* of heat per lb. of copper, which, admitting 80 per cent. electrical

efficiency for the dynamo, is equal to 2,330 units actually used. Breaking and screening the ore, and production of steam for lixiviation, use 0.32 lb. of coal per lb. of copper, or $0.32 \times 11,120 = 3,560$ units of heat, so that the total consumption is $2,330 + 3,560 = 5,890$ units of heat per lb. of copper. Considering that the matte is composed in about equal proportions of Cu_2S and CuS , which are to be reduced, about 280 units of heat are theoretically required per lb. of copper, the CuSO_4 in solution is partly electrolysed; also a good deal of $\text{Fe}_2(\text{SO}_4)_3$ is changed to FeSO_4 , so that only about 70 per cent. of the current is of actual use in precipitating the copper. The result is that about 450 units of heat may be reckoned as the energy theoretically required per lb. of copper, so that the bath alone uses $\frac{1,860}{450} =$ about four times the theoretical energy, and the total consumption $\frac{5,890}{450} = 13$ times the theoretical energy required. Allowing that the ordinary treatment of sulphides with 30 per cent. of copper by heat alone requires at least 3 lb. of coal, or 32,400 units of heat per lb. of copper, the energy used is about $\frac{32,400}{450} = 70$ times the theoretical energy required.

(2.) It can easily be shown that the treatment of sulphates of copper by this process requires at least double the energy used for the ores by process (1.).

(3.) On the Kleiner process, 0.0067 lb. of aluminium is produced per electrical HP. per hour, or 381,060 units of heat per lb. of aluminium; the Minet process gives 0.0447 lb. of aluminium per electrical HP., or 54,450 units of heat used per lb. of metal, the large difference being due to the fact that in the Kleiner process the same material is treated several times. The theoretical energy cannot be exactly stated, but the Minet process is about as efficient as the Cowles, while the Kleiner is about six to seven times less efficient.

(4.) The Cowles furnace at Lockport produced 0.03 lb. of aluminium per electrical HP.-hour, and used 4 lb. of charcoal and carbon electrode per lb. of aluminium produced. The first is equivalent to 87,950 units of heat, and the 4 lb. of carbon, burnt into CO , give $4 \times 4,469 = 17,850$, in all 105,800 heat-units per lb. of aluminium. At Milton the result was 63,420 heat-units per lb. At Neuhausen, by the Heroult process, the result was 39,850 units of heat per lb. of aluminium. The heat of formation of Al_2O_3 is about 12,850 units per lb. So that at Lockport $\frac{105,800}{12,850} = 8.2$ times the theoretical energy was used; at Milton $\frac{63,420}{12,850} =$

4.9 times; at Neuhausen $\frac{39,850}{12,850} = 3.1$ times. The author states that there is no reason why the Cowles continuous furnace should not be as efficient as the Heroult process, and then gives particulars of the Deville process, which uses about 45.6 times the theoretical energy required; and he remarks that the energy used with the Catalan furnace in reducing iron ores is about 5.9 times the theoretical energy, and that this is about double of that required with the blast-furnace.

(b.) *Yield of the Ore.*—By the Marchese process, about 92 per cent. of the metal is obtained; by the Kleiner, about the same; in the Cowles furnace, and in the Heroult process, about 66 per cent.

(c.) *Purity of the Metal produced.*—99.7 per cent. of pure copper is guaranteed by the Marchese process; the aluminium obtained by Messrs. Bernard and Minet is almost pure; by the Cowles or the Heroult process the aluminium always contains at least 10 to 15 per cent. of silicon.

In conclusion, the author states that from the point of view of energy used, the electro-metallurgical processes are superior to the ordinary ones, with the exception of process (2.); but for purity of the metal produced process (4.) is much inferior to the other three. He therefore classes them as follows in order of merit:—Thermo-electrolysis, electrolysis with a soluble anode, electro-thermal processes, leaving out altogether electrolysis with an insoluble anode, as being too wasteful.

* The unit of heat employed is the pound-degree Fahrenheit.

PATENTS.

Improvements in and Connected with Electrical Furnaces. R. E. B. Crompton, Chelmsford. Eng. Pat. 13,687, September 22, 1888. 8d.

THE temperature of the furnaces is raised to that of low incandescence by gas-jets, suitably arranged and burning with a non-oxidising flame, before the electric current is switched on, thus reducing the size of the electric plant required for a given number of furnaces.—B. T.

Improvements in Plates or Electrodes for Secondary Batteries. T. J. Hanford, London. From L. Duncan, Baltimore, U.S.A. Eng. Pat. 15,433, October 26, 1888. 8d.

THE lead plates, plain or otherwise, are made anodes in an alkaline solution of a lead salt, such as caustic soda saturated with litharge. By employing a weak current and keeping the liquid well agitated, a strongly adherent and dense oxide of lead is deposited, which is impervious to accumulator acid, and therefore protects the lead support from local action, &c. By now heating the solution and depositing rapidly, a porous coating of oxide is obtained, which serves as the active material: the ordinary methods of pasting and forming may, however, be employed. The protection given by the first coating to the lead support enables the latter to be made lighter and thinner; or other materials than lead may be employed, though these are preferably first coated with lead.—E. T.

Pocket or Portable Secondary Batteries or Accumulators. E. Rousseau, London. Eng. Pat. 15,877, November 3, 1888. 8d.

THE containing cells of these accumulators are made of glass or ebonite; if of the former material, the connecting wires are of platinum, fused into the glass; if the case be of ebonite, they are vulcanised in place. In either case, they are fused into the lead supports of the electrodes and leave the cell below the level of the electrolyte, and preferably at the bottom of the cell, where they are best protected from the gases evolved. The active material is packed between the lead support and a perforated or porous partition or cylinder of celluloid, the latter protecting the cell against disintegration. The lead supports are protected from electrolytic action by the active material, and elsewhere either by proximity to the containing cell, or by an impervious varnish.

Electrolytic gases have first to pass by one or more small apertures into a chamber where they can deposit moisture, and thence escape by another small hole to the atmosphere. The tops of the cells may be closed by an india-rubber bung, cemented into the mouth of the cell and perforated for the vent arrangement. As many cells as are required are packed into a light case and held in position by some such composition as a mixture of resin and pitch. The object is a more durable and lighter cell.—E. T.

Improvements in Electro-Plated Goods and in the Process of Manufacturing the Same. F. A. Oetzmann, London. Eng. Pat. 16,954, November 21, 1888. 4d.

THE parts of electro-plated goods which are most liable to wear are covered with a thicker coat of the deposited metal than the other parts. This extra thickness is preferably put on first, the remainder of the article being protected by a suitable varnish.—B. T.

Improvements in or relating to Dry Piles for Electrical Purposes. G. C. Dymond, London. From L. Moortbarmers, Antwerp, Belgium. Eng. Pat. 17,238, November 27, 1888. 6d.

THE cell is essentially a Leclanché cell, the containing case being of zinc and forming the positive plate, the porous cell

being replaced by a linen bag, and the electrolyte being formed into a paste with chalk or barium sulphate. The linen bag is bound with string to bring its contents into better contact.—E. T.

Improvements in Cells for Secondary Batteries. M. B. Hollies and J. Warner, London. Eng. Pat. 17,537, December 1, 1888. 8d.

THE inventors state that by enclosing their cells and preventing the escape of gases they get greater efficiency, and they describe methods of carrying this into effect.

A cover is fastened down, with a suitable luting, to the top of the cells, or a vessel containing them and capable of withstanding the pressure. This cover is held down by bolts passing through lugs on the vessel, or by metal straps passing round it and holding down the cover by nuts or cottars. In another method, the vessels are circular and have projections which rise above and overhang their tops. The covers are provided with wedge-shaped lugs, which, by rotation of the cover, wedge in under the overhanging projections and so keep the cover down.

The cover may be provided with a safety-valve and pressure-gauge, and have stuffing-boxes through which the connectors pass to the plates.—E. T.

Improvements in the Manufacture of Filaments for Incandescent Electric Lamps. H. H. Lake, London. From J. B. Tibbits, New York, U.S.A. Eng. Pat. 6104, April 9, 1889. 8d.

IN this method a carbon filament is prepared in the ordinary way and soaked in a saturated solution of tungsten trioxide dissolved in any of the fixed alkalis, it is then made incandescent by a current of electricity in an atmosphere of pure dry hydrogen, the result being that metallic tungsten is deposited upon it, which makes it much tougher and more durable. The hydrogen is perfectly obtained by distilling a pure hydrocarbon, such as naphthalene, in a retort and passing the vapour into a chamber containing a coil electrically heated, whereby carbon is deposited and hydrogen liberated.—B. T.

Improvements in Electric Accumulators or Storage Batteries. E. N. Reynier, Paris, France. Eng. Pat. 11,471, July 17, 1889. 8d.

THE active material of accumulator plates is constantly expanding or contracting during the processes of discharging and charging, but the supports do not alter correspondingly, and the result is gradual disintegration. He therefore places porous plates in the spaces between the electrodes, or protects all their faces by thin porous partitions, and employs separating combs or grids of insulating material to keep them apart. The containing case is made of flexible material and the whole is kept compressed by strong springs between pressure plates placed at the two ends of the cell. Instead of employing separate pressure plates and springs for each cell, a whole series of cells may be compressed at once by one set of springs, suitable means being taken to support the cells in the middle of the series. By thus imparting an "artificial elasticity," the inventor hopes to obviate the above-mentioned defect of disintegration.—E. T.

Improvements in Generating Electricity or Magnetism by the Application of Heat. P. M. Justice, London. From E. G. Acheson, Pittsburgh, U.S.A. Eng. Pat. 12,145, July 31, 1889. 8d.

HEAT is applied in a suitable manner to the magnetic mass of an alternate current transformer, and the secondary current is found to be materially increased, or a part of the secondary circuit of a transformer is arranged in inductive relation to a thermo-couple, producing an increase in the electrical output of the couple; or any number of thermo-couples and coils carrying an alternating current may be arranged round a magnetic core with the same effect.—B. T.

A Galvanic Battery Solution. W. P. Kookogey, Brooklyn, U.S.A. Eng. Pat. 12,402, August 6, 1889. 4*d*.

This is an improvement on Eng. Pat. 4667 of 1887, to secure a solution of chromium, sulphuric acid and water as a depolariser. By this improvement the bichromate of sodium, instead of that of potassium, is employed. Three parts of the bichromate are added to 10 of water, and 14 by weight of sulphuric acid added, when, after standing, sodium sulphate is precipitated and the solution is ready for use. The proportions may be slightly varied. Chrome alum, which is detrimental to the working of the battery, is not formed with this solution.—E. T.

A Plate for Secondary Batteries. W. P. Kookogey, Brooklyn, U.S.A. Eng. Pat. 12,731, August 13, 1889. 8*d*.

A PLATE of some material, such as ebonite, glass, or paraffined wood, is formed with taper slots through it and is bolted to a thin plate of lead, with the base of the slots

next the lead. The active material is then pressed into these slots, making contact with the lead at the back. A slotted plate may be placed on each side of the lead conductor, thus preventing all buckling of the lead.—B. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Note on the Examination of Fats. W. Thörner. Zeits. f. angew. Chem. 1889, 309.

THE following table of results is given of a chemical and physical examination of fats and tallow made in the Osnabrück "Control-station." The animal fats were melted out in the laboratory, and all the samples examined were remelted and filtered before testing:—

	Mutton Tallow.	Beef Suet.	Pig's Lard.	Palm Oil.	Palm-nut Oil.	Mixture of Beef Suet and Palm-nut Oil, 1:1.
Melting point of fat.....	55°0	48°0	37°5	25°0	28°0	29°0
Melting point of fatty acids.....	49°0	43°0	29°0	46°0	15°0	20°0
Solidifying point of fats.....	41°0	35°0	28°0	38°0	26°0	28°5
Specific gravity at 100°.....	0·8580	0·8585	0·8605	0·8605	0·8665	0·8650
Ash	0·1	0·04	0·03	0·03
Volatile fatty acids in terms n/10 alk...	0·4 cc.	0·4 cc.	0·4 cc.	0·22 cc.	2·3 cc.	2·0 cc.
Iodine absorption for fats	32·7	41·8	50·5	53·9	11·9	27·2
Iodine absorption for fatty acids	29·2	37·7	42·4	43·8	16·3	26·6
Saponification equivalent	195·2	201·3	195·2	201·3	231·0	214·2

The author has also determined the refractive index of several kinds of oils and fats by means of a new refractometer invented by Pulfrich, which he highly recommends. The following are the results obtained at a temperature of 60°.

	Refractive Index at 60°.
Water	1·3287
Mutton tallow.....	1·4504
Beef suet.....	1·4527
Lard	1·4539
Palm oil (raw)	1·4501

Mixture of 1 part of beef suet and 1 part of palm-nut oil	1·4468
Cotton-seed oil	1·4570
Olive oil.....	1·4548
Butter fat (clarified)	1·4477

—H. S. P.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

Japanese Lacquer and Wakasa Ware. Board of Trade Journal, VII. 589.

At a recent meeting of the Chemical Society at Washington, R. Hitchcock read an interesting paper on Japanese lacquer and Wakasa ware, of which the following is a brief summary, the paper itself being of considerable length:—

Japanese lacquer is the product of a tree (*Rhus vernicifera*) which grows throughout the main island of Japan. It

attains a large size, and will live for 40 years, but only comparatively young trees are valued for the production of lacquer. Having yielded for several years they are cut down, the lacquer extracted from their branches, and young trees take their places. The best lacquer comes from Yoshino, in Yamato. The lacquer exudes from horizontal cuts in the bark, in the form of a rather viscid emulsion, and may be collected from April to the end of October. In the spring it is more watery than in the later months. It exudes slowly, and is collected by means of a pointed, spoon-like instrument, and transferred to a wooden receptacle or tube of bamboo. Several cuts are made in each tree, the last as high as a man can reach. Having thus prepared a dozen or more trees in rapid succession, the collector begins to collect the juice from the cuts in regular order, beginning with the one first cut. Having finished the collecting, he takes other groups of trees, and after about four days returns to the first, where, after removing the accumulated yield, he cuts again into the same trees, and repeats the same process 15 or 20 times. Thus the work may go on for 80 to 100 days.

As the sap first exudes, it is a greyish white, thick, or viscous fluid, which quickly turns yellow, and afterwards black, where it is in contact with the air. The sap thus collected is *ki-urushi*, *urushi* being the general name for lacquer. An inferior kind is obtained from the branches when the trees are cut down. The branches are soaked in water for several months, then taken up and slightly warmed, when a small quantity of sap exudes. This is *Seshime urushi*. The lacquer is strained through cotton cloth to free it from bits of wood and dirt, first being thoroughly stirred to break up lumps and make a uniform mixture. The product thus purified is known as *Seshime urushi*; but this name, which has already been used to designate the lacquer from the branches, has now a different meaning, and is applied to the cheaper kinds of raw lacquer, such as are used for the first coats in lacquering. These lacquers

have usually lost some of their water by stirring in shallow receptacles exposed to the sun. They have undergone no further preparation.

Many varieties are prepared for special purposes, ranging in price from one or two to six or seven dollars per kilogramme. These differ in quality and colour. There is a famous black lacquer prepared by the addition of iron, which forms a chemical combination to be mentioned further on; while red, green, yellow, and other colours are imparted by the addition of various pigments, as cinnabar for red, orpiment and indigo together for green, orpiment for yellow, &c. Certain lacquers have a small proportion of drying oil (perilla oil) added to them.

The most important and abundant constituent of lacquer is urushic acid, which occurs in the form of minute spherules. The acid is obtained by evaporating the alcoholic solution to a syrupy liquid. The evaporation must be carried on over a water-bath. If too much heat be applied a tough, black, rubber-like substance is obtained, which only strong nitric acid would affect in the slightest degree. Although the drying, or rather the hardening properties of lacquer, are doubtless due to the oxidation of urushic acid, the product extracted by alcohol possesses no drying qualities. This fact was first observed by Professor Rein, in 1874. More recently Professors Korschelt and Yoshida have found that a peculiar albuminoid of lacquer affects the drying by a diastatic or fermentative action. The fact seems to be that the lacquer hardens only when the albuminous substance is present. If heated above 60° C., or above the temperature at which albumen coagulates, the lacquer will not dry. Besides urushic acid and the albuminoid, raw lacquer contains a gum resembling gum arabic, which doubtless imparts some useful properties to the lacquer, and a volatile acid, to which Professor Rein ascribes the poisonous effects of lacquer.

A portion of the raw lacquer, about 16 lb., is poured into a large circular wooden vessel, and vigorously stirred with a long-handled tool for five or six hours while the heat of a small charcoal furnace is ingeniously thrown upon the surface to evaporate the water. During the stirring certain ingredients may be added from time to time. The *roiro*, the fine black lacquer already mentioned, is made by adding iron at this stage. In Tokio a soluble salt of iron is used, but the Osaka manufacturer objects to that, asserting that it injures the quality of the lacquer. The material used in Osaka is the fine iron dust collected from the grinding of knives. This is added in quantities of about a teaspoonful of powder mixed with water at a time, until the desired colour is obtained. When the work is finished the lacquer is poured into a vessel to settle and is afterwards drawn off from the sediment.

The wood generally used for lacquer work is the light, easily worked *hinoki*, a coniferous wood. It is prepared to receive the lacquer in various ways. For inferior work it is first covered with paper, but in the finer qualities paper is not used. These operations apply to the manufacture of that variety of lacquer known as Wakasa lacquer. The wood is first carefully smoothed, and the corners of the boxes strengthened by gluing pieces of cotton or hemp cloth around them with raw lacquer. All joints and imperfections are then filled with *tsugi urushi*, which fills like putty. This is a dark-coloured mixture composed of rice-flour made into a paste with water, and mixed with *Seshime urushi*. It soon hardens, so that it can scarcely be cut with a knife. Sometimes finely cut hemp is used with it. The work is then covered with a mixture of *Seshime urushi*, and a coarse powder of a yellowish colour. The mixture is soft, of a yellowish-brown colour, changing to black by exposure to the air, and is called *jinoko*. The article is left for a few days in the open air to allow some of the water to evaporate, after which it is placed in a moist-air closet to harden. In this way a very hard gritty surface is obtained, affording an excellent ground for the succeeding coat. This process is not applied in making inferior goods.

The next process consists in covering the entire box with two coats of lacquer containing a fine powder, which is a kind of ochre much used in Japan for cleaning and polishing. This is likewise evenly spread. Three coats of this are applied over the joints. The object of this process is to secure an even, smooth-grained surface for subsequent

work. The surface is finally rubbed down with a kind of stone. The parts that are not to receive any decoration are now ready for the finishing applications of lacquer. The other parts are next covered with a black lacquer. Two coats of black lacquer are now applied. The first is *roiro* put on with a broad brush. This dries with a brilliant reflecting surface. When quite hard the second application is made, and in this, while still soft, the designs are impressed.

In the Wakasa lacquer there is no painting or drawing, but the figures are produced in a very curious manner. The white decoration is applied by dropping egg-shell powder in patches here and there. This is done very skilfully by the hand. The other designs are made by pressing various forms of leaves into the soft surface. Thus, the radiating or wheel-like pattern is produced by so arranging the needle-like leaves of the pine, the more complex leaf-pattern with the leaves of an ever-green, while many other effects are made by scattering over the surface husks of rice, and these mingled with very short pine needles. The mother-of-pearl from shells is also used. The designs become more or less modified by the subsequent operations. The lacquer retains the impressions thus produced, when, after the leaves, &c., have been embedded about a day, everything except the egg-shell powder and mother-of-pearl is removed. The article is then put in the moist closet until it is thoroughly hardened, which may require 10 days or a fortnight. The egg-shell is in little heaps, the leaf impressions are beneath the general surface. It is now necessary to fill up all depressions and once more secure an even surface. The first step is to rub down the most conspicuous projections until there is much less irregularity of surface, but even after several successive coats of lacquer there will remain some elevations and depressions. The next application is a transparent lacquer coloured yellow with arsenic sulphide. This is spread as evenly as possible. The object is to afford a yellow ground for the gold which is to follow. A thin coat of *shiu-ai-urushi* is spread over this, and the whole completely covered with gold leaf. Then successive coats of the same lacquer, which is of a transparent red, are applied until the surface is quite even. The surface then appears entirely black, beneath which all the gold and decorations are concealed.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

The Australian Wattle as a Tanning Material. United States Consular Reports, July 1889, p. 253.

ASSISTANT Commissioner Merry, writing from Melbourne, strongly recommends his Government to encourage the planting of the Australian wattle in Texas, New Mexico, and Arizona to replace the rapidly vanishing oaks of the United States, which are, moreover, of too slow a growth to be cultivated for tanning purposes. The wattle belongs to the family of acacias, and is cultivated largely in New South Wales and Victoria. The two varieties most cultivated are the black wattle and broad-leaved wattle, both of which are indigenous to an exceedingly dry climate and poor soil, and attain their growth in about six years. In moist localities they attain a greater diameter of trunk, but their bark yields less tannic acid than that grown in dry situations. The black wattle (*Acacia decurrens*) yields most tannic acid, and is therefore preferred by the trade in England, where its market value fluctuates from 7*l.* 10*s.* to 8*l.* 8*s.* per ton, according to the supply in the market. Mr. Merry states that hides can be readily tanned in a bath of liquor made from black wattle in 47 days, whereas in liquor made from Santa Cruz oak (the best found in all the Pacific States) the time required is from 75 to 80 days. The black

wattle contains from 30 to 32 per cent. of tannic acid, and the following table of percentages will show its relative value:—

	Per Cent.
Black wattle.....	30—32
Broad-leaf wattle.....	26—28
Santa Cruz oak	16—18
Siskey or mountain oak	14—16
Sacramento Valley oak.....	10—12

The broad-leaved wattle (*Acacia pycanthea*) is a larger and handsomer tree than the black wattle, and can withstand more frost, but yields rather less tannic acid.—C. G. C.

XV.—AGRICULTURE, MANURES, Etc.

On the Solubility of Thomas Phosphates poor in Phosphoric Acid. E. Jensch. Zeits. f. angew. Chem. 1889, 299—304.

THE author maintains that poor basic slags, containing from 15 to 16 per cent. of phosphoric acid, are valuable manures in opposition to views expressed by Hofeleiss (Landwirth, 1889, 107), and by Stutzer-Bonn in an essay in the Zeits. d. l. V. für Rheinpreussen (Landwirthsch. Post, 1889, No. 9).

The author in the first place takes the solubility, of the phosphoric acid contained in the slags, in citric acid as a measure of their value as manures, and shows that the phosphoric acid in poor slags is as soluble in this medium as that contained in rich slags, and concludes that the phosphoric acid in both kinds of slags is combined as calcium tetraphosphate, and not as tribasic phosphate, which is difficultly soluble in citric acid. At the same time he has made comparative experiments in various slags with regard to the solubility of their phosphoric acid in tartaric acid, acetic acid and oxalic acid, and in neutral ammonium citrate; he has also tested the solubility of the calcium silicate in the same solvents. The experiments were made upon slags from various works and of different ages, and,

for the sake of comparison, the solubility of Podolian phosphorite and of Somme phosphates was determined. One grm. of each sample was treated for about 12 hours at 50°—70° C. with 150 cc. of the solvent (strength 1:20); 100 cc. of water were then added, the whole boiled, the undissolved residue then filtered off, heated to redness and the phosphoric acid in it estimated in the usual way. A complete analysis of this residue in each case was also made. From the differences between the original analyses of the slags and the analyses of the residues the quantity of each constituent dissolved by the acid was calculated.

The following samples were operated on:—

Table I. gives the analyses of these samples, and Table II. the percentage of P₂O₅ dissolved by the organic acids.

From these tables it is seen that the solubility of the phosphoric acid contained in poor phosphates is practically the same as in rich; in the richer slags which are used

without hesitation in agriculture the amount of insoluble P₂O₅ varies from 0·02—0·13 per cent., while in the poorer slags it amounts to no more than from 0·04—0·14 per cent. The solubility in oxalic acid shows a similar correspondence, viz., in rich slags the P₂O₅ in the residue is from 0·09—0·26

per cent., and in the poorer slags from 0.08—0.21 per cent. In the case of the slag crystals the results are even more satisfactory. The solvent action of the other organic compounds experimented with is less complete, but here also a nearly equal relative solubility is shown by the different phosphates. Taking the solubility of their phosphates in citric acid as a gauge of the value of slags as manures, it is at least clear that the poorer slags, without exception, are usable, and the objection to their use is probably to be ascribed to a prejudice which experience will remove.

The author points out that the calcium silicates in basic slags are easily soluble in organic acids, thus differing from mineral phosphates, and he holds that the composition of the silicates in basic slags may be taken as a measure of their applicability as manures. The more basic the silicates the more soluble phosphoric acid is found—or, the more silicon there is in the silicates, the more phosphoric acid is found insoluble in organic acids. He considers the presence of a large excess of free lime of but little importance as affecting the solubility of the phosphates. Magnesia must be taken into account in appraising Thomas phosphates, as magnesium tetraphosphate is more soluble in organic acids than the corresponding calcium salt.

A table is also given showing approximately the composition of calcium silicates contained in the various samples mentioned above, and another table showing the ratio of the phosphoric acid (P_2O_5) to the lime in the silicates.

—H. S. P.

Effect of Phosphatic and Nitrogenous Manuring on Sugar-Beet. F. G. Budweiss. Wiener. landw. Presse, **38**, 1888, 665—666.

RESULTS obtained from numerous experiments with sugar-beet, show that “full” dressings of Chili saltpetre or phosphatic manure give rise to increased yields, whereas

“very heavy” manuring gives rise, in the case of phosphates, to no noteworthy improvement over the “full” dressing, and with nitrates to even detrimental results, so that the results are then lower than those yielded by the unmanured crop. The tables in the paper also illustrate the effect of manuring on the various portions of the plant, phosphates develop the roots, nitrate the leaves; hence where the former prevail the bulk of the root reaches as high as 60 per cent. of the whole plant, whereas when nitrate is in the ascendancy the root forms only 45 to 50 per cent. of the whole weight of the plant. A plant with 60 per cent. of root, 6 per cent. of head, and 34 per cent. of leaf, is regarded by the author as a normal plant.—D. A. L.

Manurial Experiments in the Field and in Pots.

P. Budrin. Biol. Centr. **18**, 375—379.

THE author has conducted numerous experiments in small and large plots in the field, also in pots as employed by Wagner of Darmstadt.

The small plot experiments were made for the purpose of comparing the action of Chili saltpetre and ammonium sulphate. The soil was a diluvial loam poor in humus and contained 0.5603—0.0849 per cent. of N, 0.0304—0.0607 of P_2O_5 , 0.18 of CaO; the beds were 45.5 square metres in extent and 161 in number. The manuring per hectare was 150 to 180 kilos. of Chili saltpetre, 120—180 kilos. of ammonium sulphate, 180—440 kilos. of phosphate or potash manures. The plants grown were potatoes, winter rye, winter wheat, barley, oats, field-beans, flax, and sugar-beet in triplicate or on more than three beds, whilst single beds of summer wheat, summer rye, winter and summer rape, carrots, and clover were also grown. The following table contains the mean results obtained from the more reliable experiments with grain, potatoes, and beans, the mean yield of the unmanured beds being taken at 100:—

—	Chili Saltpetre.								Mean Result with Nitrate N.

The results with the grain crops and nitrate and ammonium sulphate alone were not sufficiently numerous to be included in the above table, whilst corresponding experiments with beans were not conducted. By the application of Chili saltpetre and ammonium sulphate the following increments were obtained per kilo. of nitrogen. With grain crops the saltpetre is found better, with potatoes the ammonium sulphate.

Crop Plant.	Crop Increments Obtained.			
	With Chili Saltpetre.		With Ammonium Sulphate.

Oats.....	81	27.0	74.0	24.5
Potatoes.....	Tubers. 115		Tubers. 119	

The manures were sown immediately before the plants. Taking the increase produced by one part of saltpetre nitrogen as 100, the mean increase obtained with ammoniacal nitrogen in a great many experiments would be for cereals:—Total crop, 89.0; corn, 89.5; for potatoes:—129.5.

The field experiments on the large scale were made on a low-lying, alluvial soil, poor in humus, subject to flooding by the Vistula and very fertile. The soil contained per cent. 0.1106 of N, 0.0844 of P_2O_5 , 0.6 of CaO , and was cultivated in a four-course Norfolk rotation (winter wheat, roots, barley, and clover or vetches). The field was divided into four plots; one always received complete artificial manure; another, nitrogen and phosphoric acid; the third, phosphoric acid and potash; the fourth, nitrogen and potash. The following results have been obtained so far. Phosphoric acid produced a moderately good result with roots and cereals; nitrogen exerted a feeble or even injurious action (excessive development of straw to the detriment of the corn) on wheat and barley, and a moderately beneficial effect on root crops, as the following numbers (per hectare) show:—

Sugar-Beet.	Manuring.			
	K_2O , P_2O_5 , and N.		P_2O_5 and N.	
	Double Centners.	Sugar.	Double Centners.	Sugar.
1885	373.5	Per Cent. 14.40	432.5	Per Cent. 16.7
1886	304.2	15.50	261.9	16.0

(continued.)

(continued.)

Sugar-Beet.	Manuring.			
	P_2O_5 and K_2O .		K_2O and N.	
	Double Centners.	Sugar.	Double Centners.	Sugar.
1885	330.3	Per Cent. 15.1	387.0	Per Cent. 15.2
1886	238.8	17.2	240.6	17.2

In the wet year 1885, one kilo. of nitrogen produced an increase of 232 kilos. of sugar-beet, whereas in dry 1886, the increase was 307 kilos.

The author's pot experiments were made with millet, summer wheat, flax, and oats; the loams above described with or without sand; also pure sand were employed as soils. The manuring exerted only a very slight action on the pots filled with loam, either alone or mixed with sand, therefore the author only communicates the results obtained with oats in pure sand. The pots were 32 centimetres high by 24 in diameter. The manuring and results are shown in the following table. In the original the mean length of the plants, the number of seeds per vessel, and a numerical comparison between the unmanured and other pots are also given:—

Manuring.	Total Yield.	Corn.
Unmanured.....	Grms. 14.20	Grms. 4.71
Eight grms. of lupin-flour.....	45.16	21.32
Two grms. of Chili saltpetre.....	47.55	19.86
Two grms. of ammonium sulphate...	42.35	20.20
Chili saltpetre + superphosphate + kainite.....	56.76	22.30
Unmanured.....	13.93	5.83
Sixteen grms. of lupin-flour.....	5.70	1.38
Ammonium sulphate and kainite....	61.85	24.64
Chili saltpetre + superphosphate....	52.23	20.29
Amm.-sulphate + superphosphate...	24.43	9.98

Leaving out the last experiment, which was injured by a fall, and the bad result obtained with 16 grms. of lupin-meal, a kilo. of nitrogen yielded the following increased yields of oats in kilos.:—(For Table, see next page.)

The results with lupin-flour are important, inasmuch as in Russian Poland nitrogen in that form costs half as much as nitrogen as Chili saltpetre. The injurious action of the large quantity of lupin-flour noted in the above table is also observed with many other plants, wheat, rye, buck-

Manuring.	Nitrogen as					
	Saltpetre.		Ammon-Sulph.		Lupin-flour.

Complete artificial manure.....	133.3	53.2	119.3	48.4

wheat, flax, &c. But it is only observed when the lupin-flour is sowed on perfectly barren soil and immediately before the plant. For instance, oat plants sowed in the pots after the completion of the above experiment did not suffer, nor did summer wheat and millet which received a heavy dressing of lupin-flour immediately before sowing, but on a loamy soil. Lupin seed or flour would hence be perfectly harmless on ordinary cultivated soil, especially if sowed betimes.—D. A. L.

Comparative Manurial Experiments with Rye. G. Thoms. *Bied. Centr.* **18**, 420—421.

SEVEN experimental cultivations were made, manuring with phosphates as well as stable manure; five showed a profit and only two a loss. Superphosphate was used in six of the experiments and Thomas slag-powder for the seventh. In seven other experiments the manuring consisted of stable manure, superphosphate, and kainite, with the result that only two yielded a profit, whilst five registered a loss. These results indicate that for rye manured with stable manure, the judicious application of superphosphate will yield a profit; whereas the employment of kainite should not be indulged in extensively until the necessity for it has been proved by experiment.—D. A. L.

Peat-Litter Manure. C. Giannetti. *Le Stazioni Speriment. Agrar. Ital.* **1889**, **16**, 1—12. J. H. Vogel. *J. f. Landw.* **1888**, **36**, 455—473.

GIANNETTI obtained the following results with a peat from Ferrara, which was in an almost pulverulent condition and sufficiently dry, although it contained 24.55 per cent. of moisture. The peat was used for 12 days as litter for a cow; it was then examined:—In the first experiment, after three days, when fermentation had already commenced; in the second experiment, after 21 days vigorous fermentation; and in the third experiment, after being mixed with drainage. 200 kilos of peat made 1,300 kilos. of peat-litter manure and then deodorised 150 kilos. of drainage. The following analytical data are given, the numbers being per 1,000:—

	Moisture at 120°.	In the Dry Material.			
		Organic Matter.	N.	K ₂ O.	P ₂ O ₅ .
Original peat	244.5	821.8	29.97	0.75	5.21
Peat manure, I.	641.2	773.7	53.53	9.28	6.15
" " II.	639.6	763.6	58.40	9.44	7.38
" " III.	672.6	861.9	37.72	7.27	10.48

The dampest sample lost 0.7 per cent. of its weight of ammonia by drying at 100°. As the peat-litter is evidently a good absorbent and produces a good manure, it is, moreover, more economical than straw, and costs a third the price, therefore the author recommends its use strongly.

Vogel's experiments were made with peat and human urine. The value of the manure is indicated by the following numbers:—

	Original Peat.	The Manure.
Dry matter	78.29	15.63
Total nitrogen	0.78	0.63
(Ammoniacal nitrogen	0.08	0.20)
Ash	1.90	1.43
Total phosphoric acid.....	0.07	0.15
(Soluble phosphoric acid.....	Trace	0.17)

Two lots, each 10 kilos., of the moist peat manure, were placed in casks, one intimately mixed with 100 grms. of lime, the other without lime. After four months the latter had lost 33.72 per cent. of nitrogen, the former 31.66 per cent., and in neither was any nitric acid detected; but the proportion of organic nitrogen had increased from 34.70 per cent. to 40.04 in the lot with the lime, and to 42.36 in the other lot; which increase is attributed to retrogression of ammoniacal nitrogen. In two experiments, 2 kilos. of peat were saturated daily for 11 days, with 16 kilos. of sheep urine, in one case being mixed with 1 kilo. of the mixture, in the second case with 2.6 kilos.; whilst in a third experiment, 1 kilo. of peat was treated on three different days with sheep urine, and mixed with 1.5 kilos. of the mixture, of which finally another $\frac{1}{3}$ kilo. was added, and the whole spread over a surface of 0.45 square metre, where it remained for 10 days. Lots 1 and 2 were left 14 days in a trough; all three were then examined, with the following result:—

	Weight of Peat Manure.			Nitrogen added as Urine.		
	Theory.	Found.	Lost.	Total.	Found.	Lost in the Air.
1st lot	19.00	16.87	2.13	123.84	123.11	2.73
2nd lot	20.60	19.29	1.40	120.36	116.14	3.51
3rd lot	14.32	13.13	1.19	86.44	79.14	8.45

These results are regarded as excellent, and show the utility of using such a mixture for preventing dissipation of nitrogen from such manures.—D. A. L.

The Chemical Composition of the Aqueous Solutions drawn to the Surface Layers of Field Soils by Capillarity. L. Sostegni. *Stazioni Speriment. Agrar. Ital.* **16**, 1889, 48—49.

SOIL was placed in two zinc cylinders in the same position as it previously held in the ground; the lower part of the cylinders stood in distilled water, whilst packets of filter paper, perfectly free from mineral matter, were placed on the top. The packets were changed every 24 or 48 hours, when the absorption became very small. As soon as the water had reached the surface of the soil in the cylinders the water supply was removed from beneath them. The papers were ultimately washed and the solutions analysed. The mineral matter in the solutions varied between 1.34 and 3.97 per cent., the quantity brought to one square metre of surface in 24 hours being between 1.88 to 3.50 grms. Carbonates, sulphates, chlorine compounds, and nitrates are present in the order given.—D. A. L.

Loss of Nitrogen during Nitrification, and the Gain of Nitrogen in Soils destitute of Vegetation. B. Tacke. *Landw. Jahrbücher*, **1889**, **18**, 439—462.

It is pointed out that results obtained in all previous experiments, showing loss of nitrogen during nitrification,

are open to the objection that the substance undergoing nitrification has never been exposed to an uninterrupted access of air, and consequently the loss of nitrogen might be attributed to reduction of the nitrates already formed. The author has, therefore, made two series of experiments to investigate this point. In one series, the gases evolved during nitrification were examined, in the other series the quantity of nitrogen in the material employed was determined both before and after the experiments. The former series yielded no definite results, but the results of the latter are as given below, and were obtained in the following manner:—Garden or lupin soil was allowed to nitrify in the presence of an abundant supply of air, the latter being first purified from nitrogenous compounds by passing through sulphuric acid and potash, the air, after contact with the nitrifying substance, passed through sulphuric acid, to stop any ammonia, and then into the external air, as any other gaseous form of nitrogen would be considered as lost. The current of air was sustained by a pump. The soils were kept moist by a special arrangement; in some cases they were impregnated with ammonium chloride. The estimations of nitrogen were made in the following manner:—Firstly, to avoid errors due

to sampling a quantity of soil, 100 or 200 grms. was taken, and divided into halves, one half being used for the experiment, the other being reserved for the analyses, which were made as soon as possible. It was found that the small amount of nitric acid—the maximum was 0.003 per cent.—present in the original soil did not interfere with the estimation by Kjeldahl's method, and was of itself unimportant, as the amount produced during the experiments was considerably greater. The soil was, therefore, digested to whiteness with mixed sulphuric and phosphoric acids, oxidised with permanganate, diluted, and part of the filtrate and washings used for estimating the ammonia, which was collected in standard sulphuric acid, and titrated back with baryta water, using litmus as indicator. After an experiment, the soil was extracted with water, and the nitrogen left in the residue estimated in the above manner. For total soluble nitrogen, part of the solution was reduced by Kreusler's method, and then treated by Kjeldahl's method; for the nitric acid, another portion of the solution was evaporated to dryness with milk of lime, the residue dissolved in water, and the nitric acid reduced to and estimated as ammonia. The results are as follows:—

No. of Experiment.	Days Duration.	Material Employed.	Total Nitrogen at Commencement.	Nitrogen added as Ammonium Chloride.	Total Nitrogen after Experiment.	Per Cent. Total Nitrogen present as Nitric Nitrogen.	Gain or Loss of Nitrogen in Percentages of Total Nitrogen.
1	32	50 grms. garden soil	0.2673	0.1819	0.2719	9.24	+ 1.72

In some cases, the loss or gain scarcely exceeded error of experiment, but in others the numbers obtained were far beyond this. In no case could nitrous acid be detected in the soils, a result ascribed by the author to a perfect aëration of the soil. The author explains his results on the assumption that two opposing operations were at work in these soils: the one, loss of nitrogen by nitrification, the other, acquisition of nitrogen, in the manner suggested by Berthelot. In support of this, he points out that the conditions of moisture (20 per cent.) in experiments 6 to 11 were such as, according to Déhérain, are favourable for nitrification; but, according to Berthelot, are deleterious to nitrogen-fixing. It thus appears that the two operations go on simultaneously, and the result obtained depends upon the conditions being favourable to the one or the other. The author is of opinion that these results show, firstly, that nitrification, even in presence of an abundant supply of air, is accompanied by loss of nitrogen; secondly, that, as suggested by Berthelot, soils containing micro-organisms can fix free nitrogen from the air.—D. A. L.

Mammalian Experiments with Different Phosphates and Chili Saltpetre on Sugar-Beet. Küthe. Königsberger land. u. forstw. Zeit. 24, 1888, 27.

The author has conducted a series of five experiments in duplicate, and gives a table showing the mean results, from which it appears that increases in both crop and percentage

of sugar were obtained by the use of artificial manure, Chili saltpetre alone yielding the best result, the same quantity of Chili saltpetre, mixed with various phosphates, showing in each case smaller increases over the unmanured. The author, however, has found that Thomas slag is almost equal in effect to half its weight of superphosphate, and that the most favourable manure for sugar-beet is a mixture of Chili saltpetre Thomas slag and superphosphate.—D. A. L.

Top-Dressing Beets with Chili Saltpetre. J. Morávek. Oesterr. landw. Wochenblatt, 1889, 11—12.

A SERIES of experiments were made on a sugar-beet field; one plot remained unmanured; on a second plot phosphates and nitrate were sown broadcast, the former before the seed and turned into a depth of 20 centimetres, the latter immediately after the seed, and without harrowing. The third plot received the same quantities of the same manures, but they were mixed together and sown in the rows. In the fourth plot the phosphate alone was sown in the rows. In the fifth experiment the same quantities of manure were given as in the second and third, but the nitrate was applied as a top-dressing. The beneficial results obtained followed the above order of the experiments, the result from the fifth being the best. In another experiment the same quantity of superphosphate and nitrogen were applied, the latter in the form of ammonium sulphate, with a result about equal to that obtained with the phosphate alone (the fourth above).

Tables of results are given, but there is no reference either to the character of the soil or to the meteorological conditions which prevailed during the experiments.—D. A. L.

The Influence of Gypsum and Clay in Retaining in Open Soil Nitrogen, in Absorbing Atmospheric Nitrogen, and in Nitrification. M. Péchard. *Compt. Rend.* **109**, 445—447.

ORGANIC matter in a fermenting condition was added to a siliceous sandy soil which was kept almost dry for 18 months. At the end of that period there was a considerable loss of nitrogen, and the amount of ammonia and nitric acid remaining was also very small. The addition of a little gypsum reduced the loss of nitrogen from 70 parts per 100 to 58, and when the soil was at the same time kept moist a still greater amount of the nitric acid was found to be present. The ammonia was retained as the sulphate. In any small quantity sodium chloride does not seem to be harmful, but in larger proportion it acts prejudicially. With clay and coarse sand both the nitric acid and the ammonia increased in amount, but with fine sand there was a diminution in the nitric acid. In a mixture of clay and gypsum the loss of nitrogen was much reduced, and with fine sand there was an actual increase of nitrogen as though there had been absorption from the air. The loss of ammonia and nitric acid had also much diminished. Gypsum seems very useful in dry lands poor in calcareous and clayey matter. Its high nitrifying power also renders it very valuable for leguminous crops especially lucerne. Cereals also are benefited by its use. The author points out that agricultural experts have long recommended that gypsum should be added to phosphatic manures to cause them to approximate more closely to the more efficient superphosphates.—S. G. R.

Thomas Slag Fertiliser. United States Consular Reports, August 1889, 509.

PROFESSOR Dr. Wagner, of Darmstadt, has been experimenting on the best methods of employing Thomas slag as a manure. The results obtained are as follows:—The plants experimented with were wheat, barley, and flax, and the manures compared were superphosphate, Thomas slag in various degrees of fineness, "unopened" Peru guano, boiled bone-meal, and powdered coprolites. It was found that in order to obtain the effect which 1 kilo. of phosphoric acid in the form of dissolved superphosphate produced on the first crop after manuring, 2 kilos. of phosphoric acid in the form of slag, 3 kilos. in the form of guano, and 10 kilos. in the form of bone-meal were required. Wagner therefore deduces that so far as the first crop was concerned the Thomas slag was the cheapest, because 2 kilos. of it cost only 40 pfennigs as against 54 to 60 pfennigs for 1 kilo. of phosphoric acid as dissolved superphosphate.

As regards after-effect, in the second year the superiority of Thomas slag was still more marked. Wagner therefore recommends the use of Thomas slag, but insists that it must be derived from a reliable source, that it should contain at least 75 per cent. of fine meal, and that the proportion of fine meal and phosphoric should be ascertained by analysis on a sample of each consignment.—C. G. C.

XVI.—SUGAR, STARCH, GUM, Etc.

The Simultaneous Estimation of Saccharose and Raffinose in Commercial Products. L. Lindet. *Compt. Rend.* **109**, 115—117.

THE method most commonly used for this purpose is that in which the polarisation before and after inversion with hydrochloric acid is noted. The results obtained are not reliable because the rotatory power of inverted raffinose varies considerably with the time of heating and amount of acid

employed in the inversion. The author gives the following method. The sugar solution containing from 10—20 grms. of sugar per 100 cc. is heated in a flask on the boiling water-bath. 20 grms. per 100 cc. of zinc dust are next introduced, and then 20 cc. of strong hydrochloric acid, previously diluted with an equal bulk of water, are gradually added to every 100 cc. of sugar solution. Under these conditions the acid is almost immediately saturated, but has time enough to previously invert the sugars. The quantity of acid may be increased to 40 cc., and the time of heating prolonged to an hour and thirty minutes without affecting the result. Oxide or carbonate of zinc may be used instead of zinc; metallic zinc is, however, to be preferred, because it does not saturate the acid so quickly as the oxide or carbonate; besides which the nascent hydrogen, to a great extent decolourises the solution. The author finds the rotatory power of inverted raffinose to be + 53° at 20° C.; for inverted cane sugar the number is - 20° 1' at 20° C.

The saccharose and raffinose are calculated by means of the following formula, where p and p' represent the weights of the sugar and raffinose respectively, ρ and ρ' the polarisation before and after inversion, α and α' , the rotatory power of cane sugar (67° 3'), and of raffinose (103° 6'), β and β' the rotatory power of invert sugar (- 20° 1') and of inverted raffinose (+ 53°):—

$$p + p' = \rho \frac{N}{\left(\frac{\rho}{p + p'} \alpha + \frac{\rho'}{p + p'} \alpha' \right) l};$$

$$p + p' = - \rho' \frac{N}{\left(- \frac{\rho}{p + p'} \beta + \frac{\rho'}{p + p'} \beta' \right) l}.$$

$$p = p' \frac{\rho \beta' + \rho' \alpha'}{\rho \beta - \rho' \alpha'}.$$

By transposing the value of p in one of the above equations, the value of p' , and therefore of p , is obtained.—H. T. P.

Improvements in the Manufacture of Starch, Dextrin, Glucose, &c. *Dingl. Polyt. J.* **272**, 522—527.

AN interesting paper was read before the "Vereins der Stärke-Interessenten Deutschlands," by Saare, on the "Difference in Quality of Moist Starches." The chief impurities found are fibre, sand, and remains of the pulp water. The water varied from 47·5 to 52 per cent., the average being 48·5 per cent. The impurities ranged from 0·1 to 1·5 per cent., average 0·5 per cent. Sand averaged 0·22 per cent. Fibre was found from 0·01 to 0·3 per cent., average, 0·15 per cent. The impurities soluble in water varied from 0·08 to 0·2 per cent., mean, 0·12 per cent. To prevent the introduction of sand into the finished starch, the portion which settles in the washing tank next to the axis of the stirring apparatus should be removed and not mixed with the rest of the starch. Fibre gets into the finished starch owing to imperfect arrangement of the sieves. Pulp water remains in the starch owing to bad washing. Spoilt and sound potatoes of the same origin were also examined. In the case of spoilt potatoes a considerable loss (34—40 per cent.) takes place during the preliminary washing, besides which a large quantity of slime forms on the sieves, and a dark pulp water, which ferments later on, is obtained. The starch settles very loosely, and after draining contains 67 to 70·5 per cent. of water, whilst starch from sound potatoes contains an average of 48·5 per cent. water. The addition of 1 gm. of sulphuric acid per litre of water causes the starch to separate somewhat cleaner. Calcium bisulphite has a similar, but superior, effect. The fineness of the sieve mesh has also some influence on the purity of the starch obtained. As regards the pulpy mass remaining after the starch has been washed out, not more than 5 per cent. of the starch remaining in it should be removable by washing, and not more than 50—60 per cent. of the dry, completely washed pulp should consist of chemically bound starch.

—H. T. P.

PATENTS.

Improvements in Refining Sugar and Apparatus therefor. A. Baumgarth, Lünenburg, Germany. Eng. Pat. 17,339, November 28, 1888. 8d.

For the purification of sugar in the centrifugal machine, instead of washing the crystals by means of pouring cold water from a can, or by steam jet as is sometimes done, the author uses a very fine spray of cold water produced by a jet apparatus on the injector principle. The agent in producing the fine spray is in this instance, however, compressed air instead of steam. Using this jet at a distance of 1 metre, a centrifugal loaded with 150 lb. of sugar can be treated in $1\frac{1}{2}$ to 2 minutes with 4 lb. of water, "whilst according to the old process it required three times the quantity of water, and at least five times as long a period." A drawing is given of the jet apparatus.—A. J. K.

Improvements in Bagasse Furnaces. W. Fairweather, Glasgow. From The Babcock and Wilcox Company, New York, U.S.A. Eng. Pat. 12,393, August 6, 1889. 8d.

In combination with a bagasse furnace are used auxiliary furnaces directly under the boiler to be fired with wood or other dry fuel, and fitted like the bagasse furnace with side tuyères and passages to admit a forced cold or hot air blast. They may also be worked with a natural draught, and may be worked independently or in connexion with the bagasse furnace. The waste heat from the furnace gases between the boiler and the chimney is used for heating the air for the blast. The object of the invention is to provide means whereby steam may be generated quickly at any time without depending upon the slower process of firing the green bagasse, the combustion of the latter being dependent, in part at least, upon a hot forced draught. The particular arrangement of the compound furnace is fully described with reference to drawings.—A. J. K.

XVII.—BREWING, WINES, SPIRITS, Etc.

Syrman Vermouth Wine. M. Petrowitsch. Zeits. Anal. Chem. 28, 455—456.

This wine is prepared in Syrmia (Slavonia) by digesting ripe grapes with red wine. The same grapes may be employed 2—3 times. Below are given the analyses of a sample of Vermouth wine, and of a sample of red wine similar to that employed in its preparation. The results are expressed in grammes per 100 cc.:—

	Vermouth.	Red Wine.
Specific gravity at 15° C.....	1·037	0·9920
Alcohol	5·75	9·76
Extract	12·49	2·44
Mineral matter	0·27	0·22
Free acid	0·58	0·49
{ Volatile acids	0·10	0·05
{ Fixed acids	0·46	0·42
Tartaric acid	0·2832	0·1704
Glycerol	0·78
Sugar	10·46	Present.
Line	0·0222	0·0215
Magnesia	0·0252
Phosphoric acid	0·0537	0·0486
Sulphuric acid	0·0378

The high percentage of volatile acids may be ascribed to the mustard-flour which is added to the grapes.—H. T. P.

Rectification of Alcohol. E. Sorel. Compt. Rend. 108, 1128—1131, 1204—1207 and 1317—1320.

An attempt to explain, on mathematical principles, the fact that the stronger the alcohol delivered from the analyser of a spirit still, the more free it is from impurities of higher boiling point and the greater the quantity of good quality alcohol obtained in the first fraction.—J. M. H. M.

Copper in Wine. Zecchini and Ravizza. Le Stazioni Speriment Agrar. Ital. 16, 1889, 73.

AUTHORS find that where vines have been treated with copper preparations, the grapes in 1886 harvest contained 0·0055 grm. of metallic copper per kilo., whilst the wine contained traces to 0·1 milligramme of copper per litre. (See also this Journal, 1889, 406.)—D. A. L.

Honey Fermentation. Chemist and Druggist.

M. GASTINE, after experimenting with hydromel and other fermented honey preparations, has come to the conclusion that the reason why fermentation so often fails is that honey is too pure to afford to yeast cells the mineral substances necessary to their development. He has found that on adding to honey solutions less than 0·5 per cent. of a mixture composed of ammonia, potash, and calcium phosphates, tartrates and sulphates, when yeast is introduced under the ordinary conditions, complete and rapid fermentation is readily obtained. The proportion of the various salts is not very different from that found in ordinary grape-must, only their quantity, as compared to the total liquid, is a great deal smaller; which explains at the same time why the making of hydromel will succeed so well in old wine tuns and fail in new vessels.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

A New Artificial Coffee. E. Fricke. Zeits. f. angew. Chem. 1889, 310—311.

The sample examined by the author differed from that described by J. König (Zeits. f. angew. Chem. 1888, 680) in appearance and composition. In appearance it was not nearly so much like real coffee. An analysis gave the following results on the dried sample:—

	Per Cent.
Crude proteins.....	17·90
Fat.....	2·03
Ash.....	2·27
Woody fibre	10·83

The microscopical examination showed the presence of lupin seeds and of cells of the outer skin of some kind of grain, together with hairs probably derived from wheat grains. The presence of caffeine does not suffice to make this artificial coffee a substitute for coffee, as the value of coffee is quite independent of its contents of caffeine, and is more particularly dependent on its aroma. The bitter principle in lupin seeds is known to be injurious to man, and even if means were taken to destroy this by fermentation or steaming, it could scarcely be done with such certainty as to render the lupin seeds safe for admixture.—H. S. P.

PATENTS.

An Improved Method of Treating Rice and other Grain for Removing the Outer Skins or Coverings thereof. W. Shedlock, London. Eng. Pat. 15,499, October 27, 1888. 8d.

For the purpose of removing the outer skins or coverings from rice and other grain, the grain is usually submitted to a process of mechanical rubbing, known as the "attrition process." The object of this invention is to facilitate the above process by the simultaneous action of suitable gases such as, for instance, superheated or dry steam. Apparatus suitable for carrying on the improved process is described in the specification with reference to drawings.—A. J. K.

Improvements in the Preparation of Grain for Food. H. Hart and F. C. Hawtin, London. Eng. Pat. 17,129, November 24, 1888. 4d.

The object of the invention is to prepare a food in which the bran is entirely reduced to powder. The grain is first ground or crushed, then mixed with cold water to form a dough, rolled into thin sheets, and baked. By this process the gluten of the wheat binds the whole into a hard and brittle cake, which is then broken up and ground to a fine powder.—A. J. K.

(B)—SANITARY CHEMISTRY.

The Influence of Ventilation on the Micro-Organisms in Suspension in the Atmosphere. R. Stern. Zeit. für Hygiene, 1889, 44, through Abstr. Papers Inst. Civil Eng. 48, iv. 35.

NOTWITHSTANDING the numerous investigations that have been made to determine the numbers of germs present in the air of dwellings, and the effects of disinfectants upon such germs in sick rooms, &c., the author states that no attempts have hitherto been made to ascertain how far it is possible, by means of ordinary ventilation, to expel the micro-organisms from an enclosed space, and to disinfect the air by this simple means. To endeavour to elucidate this question, the author, on the suggestion of Professor Flügge, undertook a series of experiments at the Breslau Hygienic Institute. These experiments were directed to ascertain, further, the effect of steam upon germs floating in the atmosphere, and to test how far it might be possible, by means of air-currents due to ventilation, to remove germs from floors, carpets, and clothing. The room used for the tests was situated on the third floor of the house; it had two doors and two windows, and contained 85.41 cubic metres. The arrangements made to seal the openings and to admit and exhaust the air are described, and the mode of generating the air-currents by gas-jets and water-sprays is explained. The maximum yield of the ventilation was 2,250 cubic metres per hour, equivalent to a renewal of the air in the room 27 times, but the currents could be controlled and reduced to any extent. Experiments were made with very fine dust, specially prepared, and obtained from schools and factories; this dust was impregnated with the spores of the *Bacillus megatherium*, because this bacterium, on account of its unusual size, can readily be distinguished from others under the microscope. Other experiments were made with the spores of *Aspergillus niger* alone. The dust was disseminated through the chamber by means of a spray-producer and a Japanese fan. The spores were collected on a sand filter on the plan proposed by Petri, and cultivated on a mixture of agar-agar and gelatin. Tables of the various results are appended, and the author sums up the experience gained as follows:—

(1.) In still air the germs sink rapidly to the ground; when school-room dust is used, the atmosphere, even in the course of one hour and a half, becomes nearly germ-free. When still finer particles are used (such as the finest wool-fibre, rag-dust, and mildew spores), a longer time is of course required.

(2.) With ordinary ventilation, corresponding to a renewal of the air from once to thrice in the hour, the air does not apparently become free from germs more rapidly than it

would do by simple deposition alone (there is one slight exception in the case of a descending current in the winter time).

(3.) A more rapid rate of air-renewal, but such as is scarcely practicable without giving rise to draughts, gradually increases the influence of the ventilation on the suspended germs. The lowest limit at which such an effect begins to take place would seem, from the experiments, to be such a rate as would renew the air from six times to seven times in the hour.

(4.) A rapid and complete removal of the germs from the atmosphere of dwellings can only be effected by a violent draught.

(5.) No considerable number of germs can be detached from the surface of floors, carpets, furniture, clothing, &c., even by causing the room to be traversed by strong draughts.

(6.) The generation of steam does not effect the speedy and complete deposition of suspended germs, and it only hastens the same to a slight extent.

The Physical Action of Precipitants upon Micro-Organisms present in Water. B. Krüger. Zeits. für Hygiene, 1889, 86, through Abstr. Papers Inst. Civil Eng. 48, iv. 36.

THE fact that the germs believed to be the active agents in producing certain diseases are capable of existing for some time in water has caused the bacteriological examination of rivers, streams, and lakes to assume new interest and importance, more especially, too, because it is from these sources that the water-supply of numerous towns is derived. Investigations have shown that more bacteria are usually present in rivers than in lakes. Cramer found, as the mean of 50 experiments between October 1884 and January 1885, that 168 germs per cubic centimetre were present in the Lake of Zurich; in the water of the Lake of Lucerne, on one occasion, only 8 germs were found, and on another, 51 in the cubic centimetre, while in a like quantity of the water of the Lake of Geneva, as the mean of 10 tests, 38 bacteria were found to be present. The figures are far different in the case of lakes into which rivers flowing past populous towns discharge themselves; thus, according to Frank, the contents of the water in Lake Havel, between Potsdam and Spandau, varied at different seasons from 10,600 micro-organisms per cubic centimetre in January to 326,000 in August. From a glacier-stream Schmelek obtained from 4 to 6 bacteria per cubic centimetre; Rosenberg found, as the mean of nine tests of the water of the main above Würzburg, 662 germs in February and 823 germs per cubic centimetre in March; and the Rhine contains, between May and December, an average of 20,000 bacteria per cubic centimetre. The author discusses the various sources from which these germs are derived, the rainfall, the soil, &c. The sewage of towns is a most fertile cause of the presence of micro-organisms in river-water, many examples of which are given. The germs, after their introduction into the water, may multiply considerably, in accordance with the temperature, supply of food-stuffs, &c. Instances are given in support of this fact, and the converse also holds good; when temperature falls, or when the nutritive matters are altered in character or reduced in quantity, the germs diminish in numbers. The rapidity with which micro-organisms disappear in lakes may possibly be due to the effect of direct sunlight, the influence of which may be unfavourable; but the tendency to deposition or precipitation is of greater moment, and may perhaps play an important part in the self-purifying power of water.

The results of experiments by Bolton, Hüppe, and Frankland, in support of this settling power of micro-organisms, are discussed, and the author, finding that none of the recorded observations were entirely conclusive, decided to undertake a series of tests in order to ascertain what effect in carrying down the germs would be produced by the precipitation of matters, which neither in themselves furnished nutriment to bacteria nor had any chemical action on the water.

For these experiments he employed tall glass cylinders 21 centimetres in diameter, and 57 centimetres in height, with a content of 20 litres. The jars stood in a cellar with a temperature varying from 10° to 13° C. in summer,

and from 7° to 10° C. in winter. The water employed in all cases was service water drawn from the tap, and contained from 20 to 40 bacteria per cubic centimetre. This water was impregnated with from 50 to 120 cubic centimetres of a liquid containing a bacillus-culture of a species found in the service water. This is fully described, as also all the precautions taken in its preparation and admixture with the test liquids. The substances used as precipitants were sterilised, reduced to a fine powder in a mortar, and passed through a sieve with 900 meshes per square centimetre. The precipitants employed were clay, carbonate of lime, infusorial earth, alumina, brick-dust, charcoal, coke, and sand. Tables are given of the results with each substance, and of the number of germs near the surface, at the middle, and at the bottom of each vessel when filled with treated and untreated water. The conclusions arrived at by the author are that finely divided, chemically inert substances, when introduced into water, take down with them to the bottom the greater part of the bacteria present. The action is the more intense the slower, within certain limits, that the deposition takes place, and the greater the quantity of the precipitant employed.

In order to test the difference between the above inert substances and those capable of exerting a chemical action on the water, another series of experiments was conducted with magnesia, hard wood ash, lime, and lime and raw sulphate of alumina. Here again the results are set forth in a tabulated form, and the author's conclusion is as follows:—

“Although, as will be seen from the experiments, there is no doubt that large numbers of bacteria are carried down by substances sinking through water, this action is far more considerable when, in addition to the merely physical deposition, a chemical precipitation supervenes. In the purification of water, therefore, preference should be given to chemical treatment, and inert substances should merely be regarded as mechanical aids to the precipitation.”

Lead Poisoning by Water. Ironmonger.

IN connexion with the occurrence of lead poisoning by means of water at Sheffield, Chesterfield, and other places in England, it is of interest to note a similar state of things at Dessau, Germany, together with the effects of the remedies employed at that town. The water at Dessau previous to its distribution was absolutely free from lead, yet as many as 92 cases of lead poisoning took place, and an investigation demonstrated that the illnesses were owing to the lead taken up by the town water in the course of its distribution. The general average of a large number of analyses of the water as first drawn from the pipes showed 4.463 milligrammes of oxide of lead per litre. This quantity of lead could only be acquired in one of the following ways:—(a) Owing to the composition of the metal used for the pipes; (b) owing to certain effects of weather; (c) owing to galvanic action; or (d) owing to the composition of the water itself. Carefully conducted experiments were made in order to determine the real cause of the mischief. It was proved that when metallic tin was introduced into a lead pipe more lead was invariably dissolved, from which alleged fact it is argued by the German investigator that tin-lined lead piping is “dangerous.” But it was found finally that the mischief arose from the freedom from hardness of the water itself—a conclusion, it will be remembered, which was reached also at Sheffield. The total hardness of the water was only 2.5° to 2.8° of the German scale, each degree being equivalent to 10 grms. of lime per cubic metre. When the hardness of the water was increased to 5° or 6° by agitating the water with finely-powdered limestone it no longer dissolved lead, but the reaction was proved by subsequent experiments to be due, not to the greater degree of hardness, but to the removal of the carbonic acid gas, the absence of which rendered the water incapable of dissolving lead. Various experiments were made in order to get rid of the gas, and finally an apparatus was arranged to mix the powdered limestone and the water automatically. The apparatus treats about $\frac{1}{25}$ part of the water-supply with about 200 cubic centimetres of the powder every two minutes, and the water

so treated then mixes with the rest of the supply. This arrangement is said to have effected a complete removal of the mischief, and lead in solution has almost entirely disappeared from the water-supply of Dessau.

(C)—DISINFECTANTS.

The Disinfecting Properties of Creosote. C. Fränkel. Zeit. für Hygiene, 1889, 521, through Abstr. Papers Inst. Civ. Eng. 48, iv, 39.

LAPLACE had first shown that the disinfecting power of solutions of corrosive sublimate and phenol is very considerably increased by the addition of acid, and he demonstrated the fact that the so-called 25 per cent. carbolic acid, which is inert and comparatively useless for disinfecting purposes owing to its insolubility, is, when treated with sulphuric acid, converted into a powerful disinfectant, soluble in water and watery fluids. The author had occasion to repeat the experiments of Laplace, and used for this purpose a mixture of equal weights of raw (25 per cent.) carbolic acid and pure concentrated sulphuric acid, slowly added to one another with due precautions, to avoid excessive heating. In first making the mixture without these precautions, great heat was evolved, but when care was taken to cool the vessel, and to add the sulphuric acid slowly, a sulphocarbolic acid was produced, which was tested separately to that which had become heated. Both samples were tested as 5, 4, 2, and 1 per cent. solutions, and, for the purpose of comparison, similar solutions of pure crystallised phenol and of concentrated sulphuric acid were examined in a similar way. The test objects were anthrax spores dried on to silk threads, and the cultures took place at blood-heat in prepared bouillon. The results are set forth in a table, and show the marked superiority of the mixture prepared cold to that which was allowed to become heated. The general results differ in many respects from those obtained by Laplace, and the author considers that this may be due to the nature of the anthrax spores used, for it is now known that certain varieties of these spores have much greater powers of resistance than others; and a mode of testing the powers of endurance of such spores is proposed, namely, by the period they can resist a 5 per cent. solution of pure crystallised phenol. Those spores which can survive a 20 to 40 days' exposure to such a solution to be classed as “highly resisting”; those withstanding an exposure of from 10 to 20 days as “moderately resisting”; and those destroyed in less than 10 days as “weakly resisting.” The reason of the superior action of the cold preparation of the acid mixture is discussed, and is considered to be due to certain highly poisonous compounds described by the author.

Experiments on the Practical Disinfection of Excrementitious Substances. S. von Gerlőczy. Deutsch. Vierteljahrsschr. für öffentl. Gesundheitspflege, 1889, 433, through Abstr. Papers Inst. Civ. Eng. 48, iv, 40.

THESE experiments were carried out in the course of the past year at the Pesth Hygienic Institute, in order to test the real values of the various substances employed as disinfectants, concerning which much difference of opinion had been expressed. The author divided the matters to be disinfected and deodorised into five groups, viz.:—(1), night-soil from cess-pits; (2), liquids from sewers; (3), solid contents of street gulleys; (4), dry road scrapings; and (5), fresh excreta of patients suffering from acute diarrhoea and typhoid fever. The disinfectants used were:—(1), corrosive sublimate; (2), iron sulphate; (3), zinc sulphate; (4), copper sulphate (for comparison); (5), crystallised carbolic acid; (6), raw carbolic acid (two descriptions of which are obtainable, that employed by the author, known as 50 to 60 per cent. solution, actually contained 18.7 per cent. of carbolic acid); (7), carbolised lime, commercially known as 5 per cent., but yielding on analysis 2.1875 grms. of carbolic acid per 100 grms.; (8), creolin; (9), α -oxynaphtholic acid. On the score of their extreme cheapness, the author used also—(10), raw concentrated sulphuric acid; (11), freshly slaked lime; (12), boiling water; (13), hot and cold solutions of wood-ash lye (specific

gravity of the lye 1.037, equivalent to 4 per cent. of carbonate of potash); (14). solution of common salt, containing 26.1 per cent. of salt. Specimens of the disinfected materials were withdrawn on a platinum needle, and introduced into warm fluid peptone-gelatin. The cultivation took place both at ordinary temperatures, and also at a temperature of from 35° to 37° C.

The specimens were examined at intervals of 24 hours, 48 hours, and from three to four days after treatment.

Group I.—*Night-soil*.—Samples for experiment were obtained from a night-soil removal contractor; 100 grms. were placed in a glass vessel, and treated with weighed quantities of each of the disinfectants enumerated, in various proportions. The results are set forth in detail, and they show that a practical disinfection of night-soil is all but impossible, as even 2.5 per cent. of corrosive sublimate is insufficient to render it germ-free; this quantity would entail a cost of 150 gulden per cubic metre (9*l.* 11*s.* 1*d.* per cubic yard). Complete sterilisation resulted from the use of a 4 per cent. solution of copper sulphate, and it would appear from this that with this material 1 cubic metre of night-soil could be disinfected at a cost of 12 gulden (1*l.*). For the purpose of deodorisation, the use of raw carbolic acid may be regarded as successful.

Group II.—*Sewage Water*.—Was treated with the foregoing disinfectants in a similar way, full details of the experiments being given. Here again the author draws attention to the extraordinary value of copper sulphate, a solution of 1 per mille sufficed to destroy all germs, and rendered the liquid clear and inodorous.

Group III.—*Sudge from Gulleys*.—The series of experiments recorded shows the extreme difficulty of disinfecting thoroughly this substance. For deodorisation, carbolised lime in moderate quantities sufficed, but the author recommends the use of raw carbolic acid diluted to 1 per mille.

Group IV.—*Street Sweepings, &c.*—Owing to the last cholera outbreak in Pesth the authorities ordered that carbolised lime should be freely used in the dwelling-houses, and they caused it to be strewn along the roads, against walls, under doors, and over gully-holes. The author therefore carried out special experiments to test the value of this treatment, and to ascertain how far it might be possible to practically disinfect road sweepings. Treated with the foregoing disinfectants it became manifest that complete disinfection was out of the question. Even where thoroughly soaked with solutions of corrosive sublimate, copper sulphate, &c., the road dust was far from sterile, nor did experiments with respect to the strewing of carbolised lime yield satisfactory results. The advantages of this mode of disinfection are illusory.

Group V.—*Disinfection of Excreta*.—In certain cases it becomes of the utmost importance to thoroughly and rapidly sterilise the dejections of patients. The excreta used for these experiments were in all cases diluted with three times their weight of water. All the various disinfectants were tried in different proportions, and the results of the experiments are recorded. The conclusions arrived at by the author are:—That a strong solution of copper sulphate should be used, at least 1 gm. of the disinfectant being added to 100 cubic centimetres of excreta; but still better results arise from the employment of thrice their weight of boiling lye (2 parts of water to 1 part of wood-ashes). Milk of lime (1 part of slaked lime in 20 parts of water), used in the proportion of $\frac{1}{2}$ to $\frac{1}{10}$ of the weight of the excreta, likewise disinfects cheaply and well.

XIX.—PAPER, PASTEBOARD, Etc.

The Behaviour of Wood and Cellulose at High Temperatures in Presence of Water. H. Tauss. *Dingl. Polyt. J.* **273**, 276—285.

THE materials used in these experiments were pure Swedish filter-paper and fine chips of beech and pine woods. The extractions at the ordinary pressure were performed in glass vessels, those at increased pressures in a Möncke's digester. The extracts obtained were always more or less yellow in colour, turning brown on exposure to air, and deposited on evaporation a black, resinous precipitate, soluble in alkalis. This precipitate was filtered off and the solution further examined. The solutions contained more or less solid matter and all reduced Fehling's solution. They yielded a small extract to ether, which gave a colour reaction with phloroglucol and hydrochloric acid. The cellulose extracts all gave a red colouration with phloroglucol, similar to that given by dextrose. The wood extracts yielded a blueish-violet colouration.

1. *Extraction of Wood and Cellulose at the Normal Pressure*.—20 grms. of cellulose were boiled with 1 litre of distilled water and yielded only traces of extract; however, the concentrated solution distinctly reduced Fehling's solution. Phloroglucol and hydrochloric acid gave a red colour.

20 grms. of beech, boiled three times, each time with 1,000 cc. of water, for three hours, gave:—

Solid Matter.	1.	2.	3.	Total.
On 20 grms.	0.76	0.44	0.25	1.45
On 100 grms.	3.80	2.20	1.25	7.25

Containing sugar reckoned as dextrose:—

—	1.	2.	3.	Total.
On 20 grms.	0.313	0.140	0.02	0.473
On 100 grms.	1.565	0.700	0.100	2.365

Phloroglucol gave a red colouration.

20 grms. of pine wood boiled for three hours with 1,000 cc. of water gave:—

Dry Residue.	1.
For 20 grms.	0.236
For 100 grms.	1.180

Containing sugar—

For 20 grms.	0.035
For 100 grms.	0.175

Reaction with phloroglucol as before.

2. *Extraction at 5 Atmospheres Pressure*.—20 grms. of cellulose, with 1,000 cc. of water, heated three hours:—

Solids.	1.	2.	3.	Total.
On 20 grms.	0.148	0.080	0.049	0.277
On 100 grms.	0.740	0.400	0.245	1.385
Sugar:—				
On 20 grms.	0.021	0.0025	0.0012	0.0247
On 100 grms.	0.105	0.0125	0.0060	0.1235

Phloroglucol and hydrochloric acid gave a red colouration.

20 grms. of beech treated with 1,000 cc. of water for three hours:—

Solids.	1.	2.	3.	Total.
On 20 grms.	4'32	0'800	0'25	5'35
On 100 grms.	21'60	4'00	1'25	26'75
Containing sugar:—				
On 20 grms.	1'971	0'237	0'03	2'238
On 100 grms.	9'85	1'185	0'15	11'190

Under the same conditions 20 grms. of pine wood gave:—

Solids.	1.	2.	3.	Total.
On 20 grms.	3'08	0'613	0'142	3'835
On 100 grms.	15'40	3'065	0'710	19'175
Containing sugar:—				
On 20 grms.	1'60	0'20	0'015	1'815
On 100 grms.	8'00	1'00	0'075	9'075

Both yielded blue or bluish-violet colourations with phloroglucol and hydrochloric acid.

3. *Extraction at 10 Atmospheres.*—10 grms. of cellulose + 1 litre of water heated for three hours gave:—

Solids.	1.	2.	3.	Total.
On 10 grms.	0'944	0'384	0'020	1'348
On 100 grms.	9'44	3'84	0'20	13'48
Containing sugar:—				
On 10 grms.	0'394	0'145	0'010	0'549
On 100 grms.	3'94	1'45	0'10	5'49

Phloroglucol gave the dextrose reaction distinctly.
10 grms. of beech treated as before:—

Solids.	1.	2.	3.	Total.
On 10 grms.	1'368	0'412	0'061	1'841
On 100 grms.	13'68	4'12	0'61	18'41
Containing sugar:—				
On 10 grms.	0'424	0'086	0'021	0'531
On 100 grms.	4'24	0'86	0'21	5'31

10 grms. of pine wood treated same way gave:—

Solids.	1.	2.	3.	Total.
On 10 grms.	1'178	0'312	0'120	1'610
On 100 grms.	11'78	3'12	1'20	16'10
Sugar:—				
On 10 grms.	0'340	0'085	..	0'425
On 100 grms.	3'40	0'85	..	4'25

With phloroglucol and hydrochloric acid, blue-violet colours were obtained.

4. *Extraction at 20 Atmospheres.*—At this pressure cellulose was completely changed, being turned into a jelly-like mass, which on drying could be powdered. Its elementary composition was:—

	Per Cent.
C	42'37
H	6'30
O	51'33
	100'00

The cellulose had been hydrated to hydrocellulose $C_{12}H_{22}O_{11}$. Phloroglucol turned it red.

10 grms. of beech exposed to the same temperature yielded solid matter:—

	Grms.
On 10 grms.	0'326
On 100 grms.	3'26

Containing sugar:—

On 10 grms.	0'14
On 100 grms.	1'408

A formation of hydrocellulose was not observed.

The sugars have been stated as dextrose all through, but it is probable that other sugars are formed. No trace of vanillin could be detected in the extracts. The colour reactions obtained with phloroglucol are very similar to Ihl's carbohydrate reactions (this Journal, 1887, 306; 1888, 511.)
—H. T. P.

PATENT.

A New or Improved Machine for Preparing or Finishing Wood Pulp and other Vegetable Fibres for Making Paper. J. H. Shorrocks, Darwen. Eng. Pat. 15,956, November 5, 1888. 8d.

THE apparatus consists of a cylindrical vessel furnished with angular projections in the form of a screw from end to end. Inside the cylinder a shaft revolves carrying a number of knives which operate between the fixed knives placed on the upper part of the cylinder. At one end the shaft carries a screw to push the pulp forward after having been delivered to the machine from a hopper. Drawings accompany the specification.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Ecgonine and Anhydro-ecgonine. A. Einhorn.
Ber. 22, 1495.

It follows from the optical properties of cocaine that an asymmetrical carbon atom is contained in the pyridine nucleus, and it has been shown that the side chain in cocaine is in the α -position.

Ecgonine and anhydro-ecgonine in the form of the hydrochlorides, dissolved in water, are optically active and are laevo-rotatory.

The specific rotatory power is—

For ecgonine hydrochloride $(\alpha)_D = 57^\circ$,

For anhydro-ecgonine hydrochloride $(\alpha)_D = 61.5^\circ$.

Ecgonine differs from anhydro-ecgonine in containing a second asymmetrical carbon atom, a difference which may be expressed by the following formula:—

—J. B. C.

Some Derivatives of Parahydroxyphenyl Acetic Acid and the Ethereal Oil of White Mustard. H. Salkowski. Ber. 22, 2137—2144.

Will and Laubenheimer (Ber. 12, 2381) have shown that the nitrile of an acid having the formula $C_8H_7O_3$ is obtained when the precipitate produced by the addition of silver nitrate to the sinabin of white mustard seeds is decomposed by sulphuretted hydrogen, and have suggested that this acid is closely allied to the *p*-hydroxyphenylacetic acid, previously described by the author (Ber. 12, 1138), but do not consider it identical with the same, but as more probably being an *o*-hydroxyphenylacetic acid. Bayer and Fritsch (Ber. 17, 971) have shown that the ortho-acid has quite different properties from those of the acid obtained from sinabin, the formation of the nitrile of which may be represented by the following equation:—

Nor is the acid identical with the *m*-hydroxyphenylacetic acid prepared by the author (Ber. 17, 507), so that it (provided it is an hydroxyphenylacetic acid) must be identical with the para-acid, a fact which is fully borne out by the author's work. The nitrile of parahydroxyphenylacetic acid or *p*-hydroxybenzylamide, $C_8H_7ON \cdot CH_2 \cdot N$, melts at 69° — 70° as does the nitrile obtained as above from sinabin; the solubilities of the two are identical and the measurements of the crystals correspond most closely. As to the acids, that obtained from sinabin melts at 144.5° , that formed synthetically at 148° ; they further resemble one another in their calcium and barium salts, the former of which crystallises with four and the latter with one molecule of water of crystallisation. These facts are sufficient in the author's opinion to confirm the identity of the acid from sinabin with *p*-hydroxyphenylacetic acid. Similarly he looks upon sinabin mustard oil, the product of the action of the ferment myrosin on sinabin according to the following equation—

as *p*-hydroxybenzyl mustard oil, $C_8H_7(OH)(CH_2NCS)$, and he has prepared this substance by the action of carbon bisulphide and mercuric chloride on para-hydroxybenzylamine $C_6H_4(OH)(CH_2NH_2)$. It possesses a burning taste and raises a blister on the skin, but far more slowly than allyl mustard oil does. The characteristic mustard oil smell is only made apparent on warming the oil; it is insoluble in water, soluble in dilute alkalis, and only slightly volatile with steam. This product has not yet been obtained pure.

A number of derivatives of *p*-hydroxyphenylacetic acid are described in the paper.—C. A. K.

Mandragorin. F. B. Ahrens. Ber. 22, 2159—2161.

THE alkaloid extracted from the root of the *Mandragora* by means of alcohol is purified by converting it into the mercuric chloride double salt, decomposing this after recrystallisation, by means of sulphuretted hydrogen and separating the alkaloid by the addition of potassium carbonate to the hydrochloride thus obtained. The base is best extracted by a mixture of chloroform and ether, when, after distilling off the solvent and drying over sulphuric acid, it forms a colorless, transparent vitreous mass, which is very hygroscopic, without smell, and soluble in the ordinary solvents. The hydrochloride forms deliquescent needles. The double salts with the chlorides of gold, platinum and mercury are very characteristic, and have been analysed with a view to the determination of the empirical formula of the alkaloid. This approaches most nearly to $C_{17}H_{23}NO_3$, whence the alkaloid does not appear as an isomer of atropine, $C_{17}H_{23}NO_3$, as formerly suggested by the author (see this Journal, 1889, 814—815); still the

difference in the analytical data required is very small. The two alkaloids referred to in the previous paper appear on further examination to be identical. The gold double salt, $C_{17}H_{23}NO_3 \cdot HCl \cdot AuCl_4$, forms gold-coloured crystals which melt at 153° — 155° ; the platinum double salt, $(C_{17}H_{23}NO_3 \cdot HCl)_2 \cdot PtCl_4$, crystallises from hot water in yellow tables, and melts with decomposition at 193° — 194° ; the mercuric double salt crystallises from water or from alcohol in needles or tables, and melts at 159.5° — 160.5° .

The following reactions are characteristic of the salts of mandragorin:—An aqueous solution of picric acid gives a slightly yellow crystalline precipitate; phospho-tungstic acid a white precipitate, and iodine in potassium iodide an oily periodide. Potassium ferrocyanide gives no reaction, and no colourations are produced by the mineral acids. Introduced into the system or brought directly upon the eye, the simple salts of the new alkaloid produce mydriasis. The *Mandragora* obtained from Sicily and from Venice yielded very little of the alkaloid, whilst that from Trieste was found to be much richer, a fact due either to the plants being of different species or to their being in different stages of growth when examined.—C. A. K.

The Oils of Wintergreen and Birch. H. Trimble and H. J. M. Schroeter. American Journal of Pharmacy, August 1889.

I. PREVIOUS investigators have found oil of wintergreen to consist of methyl salicylate and a hydrocarbon, called gaultherilene; and oil of birch to be composed of methyl salicylate alone.

II. The authors find, in addition to methyl salicylate, in both a hydrocarbon of the formula $C_{15}H_{22}$, and small quantities of benzoic acid and ethyl alcohol. The amount of the hydrocarbon is from 0.3 to 0.447 per cent., and it becomes solid on standing a short time or on cooling. It is probably made up of a solid and liquid portion.

III. The oils are physically and chemically identical. The only difference detected being in the melting point of the hydrocarbons. That from wintergreen melted at from 10° to 15° C., and that from birch at 18° C. This may depend on the time of collecting the plants or on the age of the oils.

IV. A representative sample of artificial oil of wintergreen possessed the physical properties, but not the chemical composition of the natural oils, nor was it pure methyl salicylate.

V. The artificial product, when unmixed with the natural oils, may be identified by the addition of excess of potassium hydrate, when all odour of wintergreen will disappear.

VI. It would be undesirable in the next Pharmacopœia to replace the almost pure natural oils by an impure methyl salicylate of variable and uncertain composition. No reasonable objection can be offered to the designation by the Pharmacopœia, as oil of wintergreen, the product from either of the natural sources.

Some Modes of Producing Ammonio-Chlorides of Mercury. G. Audré. Compt. Rend. 108, 1108—1110.

IF mercuric chloride be precipitated by an equivalent of potassium hydrate, and ammonium chloride be then added, the yellow oxide gradually becomes white, and the precipitate eventually contains the mixture NH_2HgCl (tetramercurammonium chloride of Weyl), NH_2HgCl (mercury chloranide), and $NH_2(Hg_2O)Cl$ (dimercurammonium chloride), the second of these substances being formed by the action of sal-ammoniac on the first, and the third by the action of water on the second. The smaller the excess of sal-ammoniac, the more tetramercurammonium chloride is formed. In boiling solutions the tetramercurammonium chloride is formed, being stable, and mixed with it is the dimercurammonium chloride, $NH_2(Hg_2O)Cl$, into which the chloranide is resolved by heat.—J. M. H. M.

*Modes of Production of Ammonio-Mercuric Chlorides.*G. André. *Compt. Rend.* **108**, 1164—1167.

Action of ammonia on a mixture of mercuric chloride and mercuric oxide.—On adding ammonia to a solution of mercuric chloride partly precipitated by potassium hydrate, and shaking, the yellow precipitate gradually changes to a white one, containing NH_2HgCl and $\text{NH}_2(\text{Hg}_2\text{O})\text{Cl}$.

Action of mercuric chloride on a mixture of potassium hydrate and ammonia.—A precipitate is formed containing NH_2HgCl , NH_2HgCl , and $\text{NH}_2(\text{Hg}_2\text{O})\text{Cl}$. If the ammonia is in excess, no NH_2HgCl is formed.

Action of potassium hydrate on mercury chloramide.—If the precipitate, NH_2HgCl , produced by ammonia in a solution of mercuric chloride, be washed and heated with potassium hydrate, it is gradually converted into NH_2HgCl ; a portion of it is also converted by the action of water into $\text{NH}_2(\text{Hg}_2\text{O})\text{Cl}$. (Compare preceding abstract.)—J. M. H. M.

Chinese Method of Extracting Opium. J. Calvert. *Western Druggist*, **9**, 238.

THE preparation of "chandu," or the aqueous extract of opium which is used for smoking, is carefully kept secret by the Chinese, but the author has been able to observe the process. The opium cake is placed in tepid water in order to soften the covering, which is removed by hand. The cake is then placed in a shallow brass pan, gently heated over a charcoal fire, and as the mass becomes soft it is kneaded with a pestle and spread all over the sides of the pan, the greater part of the water being gradually expelled. The cake is then turned and heated cautiously over a direct flame until the crust becomes sufficiently hard, after which it is roasted on a gridiron over a charcoal fire until completely friable. It is then placed in a copper or brass vessel, covered with tepid water, and allowed to remain until the next day, when the infusion is poured off and the residue extracted twice with tepid water in a similar manner, care being taken to break the crust as little as possible. The infusion is filtered through muslin. Only the first and second infusions are used for the preparation of the extract; the third infusion and the washings being used in the next operation.

The first two infusions are mixed with egg albumen and boiled in a copper vessel, the scum being removed and fresh infusion mixed with albumen being added from time to time until the extract is sufficiently concentrated, when it is removed from the fire and cooled, with continual stirring, in a rapid current of air.

18 lb. of the best Turkish opium yield about 10 lb. of extract. No loss of morphine could be recognised, and hence it would seem that the extractive matter prevents the decomposition of the morphine compounds present in the original opium.—C. H. B.

Oxychlorides of Mercury. K. Thümmel. *Arch. Pharm.* **27**, 589.

By the action of mercuric oxide on mercuric chloride five oxychlorides have been isolated, and only five, all other supposed oxychlorides being found to be mixtures only. Those isolated are:—

Mercuric oxydichloride.....	$\text{HgO} \cdot 2 \text{HgCl}_2$
Mercuric monooxychloride ...	$\text{HgO} \cdot \text{HgCl}_2$
Mercuric dioxychloride	$2 \text{HgO} \cdot \text{HgCl}_2$
Mercuric trioxychloride.....	$3 \text{HgO} \cdot \text{HgCl}_2$
Mercuric tetroxychloride	$4 \text{HgO} \cdot \text{HgCl}_2$

The *oxydichloride* is contained in all mercuric chloride solutions which have been treated with mercuric oxide. The best method of obtaining it is to heat on the water-bath 1 part of oxide and 10 parts of chloride until no further yellow precipitation takes place. The product may then be washed free from chloride.

The *monooxychloride* has not been obtained in a state of purity.

The *dioxychloride* may be obtained red or black. The red modification is obtained by treating mercuric chloride with sodium bicarbonate (1 mol. of chloride to 2 mols. of

bicarbonate). The black modification is formed when the oxide is added to hot solutions of the chloride. The red dioxychloride is transformed, on heating, into the black polymeric form.

The black modification on treatment with caustic soda gives red oxide; the red modification similarly treated gives yellow oxide.

The *trioxychloride* can be got pure by treating freshly precipitated yellow oxide with chloride solution; or by similarly treating red oxide made into a paste. In the former case the product is light yellow; in the latter reddish yellow.

To obtain the *tetroxychloride* shake up an aqueous solution of chloride with red oxide (1 to 6). It is reddish brown to bronze in colour.

All the mercuric oxychlorides heated dry give a sublimate consisting of a mixture of mercuric and mercurous chlorides.

—T. L. B.

New Method for the Preparation of Pharmaceutical Extracts. A. Vée. *J. Pharm. Chim.* [5], **20**, 52.

ALTHOUGH good extracts may be obtained on a small scale by evaporation on the water-bath with certain precautions, yet on the large scale this process cannot be satisfactorily carried out. Evaporation in vacuo has also its disadvantages, such, for instance, as evolution of aromatic substances. The author makes use, therefore, of the system of concentration by freezing. If water containing only a small quantity of substance be frozen, the ice forms in compact masses, which interfere with the agitators and render it necessary to break up the ice in order to obtain the mother-liquor. He finds, however, that if but a relatively small quantity of extractive be used (which need not exceed that of the natural plant juices), the ice formed is so fine that the mother-liquor may be separated directly by means of a centrifugal machine. Hence only the products of the first maceration are taken. If the product is to take later on the form of a syrup, sugar may be added to the liquid about to undergo concentration in this manner. A methyl chloride refrigerator is used, which cools down a calcium chloride solution to -12° to -18°C ., and this circulates round the copper containing-vessels, whose interior is plated with nickel.

Some substances cannot be concentrated in this manner, probably because at lower temperatures they form crystallisable hydrates. Such a body is the hydrocyanic acid in cherries, and also sulphuric acid, which is used as solvent for alkaloids.

The liquids concentrated by the method here described contain about two-thirds their weight of water. This may be removed wholly or in part by means of hygroscopic substances in vacuo. Concentrated sulphuric acid and also burnt lime serve the purpose. Layers not exceeding 1 cm. in depth may be sufficiently dehydrated by this means in two or three days.—T. L. B.

Cocaine in Yellow Fever. United States Consular Reports, July 1889, 313.

CONSUL Vifquain, writing from Colon, states that Dr. James Thornton, resident physician and surgeon of the Panama Railroad Company, has for some time used cocaine with success as an anti-emetic in cases of yellow fever. He has never seen any toxic effects from its use. The mixture contained 10 grains of cocaine hydrochlorate, and was administered every hour. Before the use of cocaine the mortality was from 50 to 55 per cent., but out of 20 cases treated with cocaine only three were fatal.—C. G. C.

The Manufacture of Quinine in India. Board of Trade Journal, VII. 545.

Allen's Indian Mail for 14th October last, with reference to the recent attempts to introduce the manufacture of quinine in India, has the following:—

It is now some little time since the plant and apparatus for the manufacture of quinine were procured and erected at the Naduvatam cinchona plantation, and the public in

general, and planters in particular, would be glad to hear what Messrs. M. A. Lawson and D. Hooper have to say about the working of the new method. These gentlemen have been ready to give every possible information, and in showing the details of the process to all interested in the subject; but a short report, available to the public, would now be acceptable. It has often been questioned whether a factory for the manufacture of quinine could be profitably started in India, and, up to the introduction of the process now in use at Naduvatan, the answer has been in the negative. Now, however, tangible results have been achieved, as the 10 lb. jars of sulphate of quinine, equal in purity to Howard's, which may be seen at the factory, should convince the most sceptical. The next question is, can the drug be produced in paying quantities; or is it—like most of the gold in Wynaad—undeniably there, but too expensive to produce? It has been asserted that Government is manufacturing quinine at a loss compared with the market price, but it must be recollected that Government, when it started the present enterprise, did so more with the view of proving a process than of making a commercial success. It does not follow because the manufacture on an experimental scale does not pay, that it should not do so when properly conducted on a commercial scale. It may seem rather surprising that cinchona planters or others interested have not moved yet in the matter of starting a factory, but there is an explanation of this in the fact that Government will give no guarantee as to its future action, and it is obvious that whilst this is the case, nothing can be done, and private enterprise is completely checked. With large supplies of bark at hand, a genuine factory in working order, which could be enlarged so as to meet any requirements at any time, and a congested market, it is obvious that Government could, whenever it chose, completely rule Indian prices for quinine; and though at present we are assured that there is no intention of interfering with private trade, yet it is distinctly laid down that Government will not fetter itself by promises of any kind. To business men this is very unsatisfactory, and it is to be hoped that the Government will take the matter into reconsideration, and resolve on its future course. There has been great discontent amongst planters, and we do not know that it has in any way lessened, at Government retaining a large interest.

Indian Morphia. Chemist and Druggist.

FOR the second time within the past year or two a consignment of morphia from the Indian Government has been offered for sale in Mining Lane this week, and was disposed of at a price a little below the market value of muriate of morphia. The Indian muriate is not pure, being of a light-brown colour and irregularly crystalline, there being hard tufts of agglutinated crystals mixed in fair abundance with the major portion of detached crystals. We find that the sample contains barely 96 per cent. of pure morphine hydrochlorate, and is free from any notable impurity saving the colouring and extractive matters, and a little uncombined morphine. This result agrees closely with that obtained by the authors of *Pharmacographia Indica* from a sample obtained from Ghazipore, their figures being 96.6 per cent. of morphine hydrochlorate, 0.828 per cent. of uncombined morphine, 0.812 per cent. of chloroform extractive, and 0.063 per cent. of ash. The sample in that case was white. Indian morphia is manufactured at the Government laboratories, Ghazipore, from opium which has been confiscated owing to adulteration, and which is consequently unfit for making provision opium and *abkari*—i.e., opium for local consumption. Contraband opium which is not pure is also used for alkaloid making, and the total quantity of all kinds so employed is about 17,000 lb. a year. As the yield of morphia salts from this quantity falls a little short of 300 lb., or 1.7 per cent., it is obvious that the opium employed is very poor stuff. The process of manufacture employed at Ghazipore is practically the same as that recommended in the British Pharmacopœia. The opium is exhausted with water, filtered, evaporated to a syrup, calcium chloride added,

and evaporation continued until on cooling the mixture sets into a mass of morphia crystals. This mass is subjected to pressure and re-solution in order to get rid of the codeia, &c., and finally is dissolved in water, precipitated with ammonia, converted into the hydrochlorate, and crystallised. We presume that it is the product of this stage which has come to Mining Lane, for the muriate as finally turned out is "nearly white," and is so made by a method which is worth mentioning. The morphia manufactured is mostly used for native consumption, and as there is a caste prejudice against anything which has been brought into contact with animal matter, bone-black cannot be used for decolourising. Wood charcoal has to take its place; and experience has shown that charcoal from *Balea frondosa* is most suitable, as it is almost free from saline matter. Two ounces of this are used for each pound of the morphia. In addition to the latter a little over 30 lb. of codeia is manufactured every year. It will be seen from the foregoing that there is no immediate hope of getting any important supplies of morphia from India; moreover the Government has given a distinct promise not to manufacture and sell either morphia or quinine in such quantity as would disturb the market. What they do is to dispose of their surplus stock merely, and any small jobber will be able to buy the whole of that when it appears.

PATENT.

Improvements in the Manufacture or Production of Para-oxibenzoic Acid. J. Y. Johnson, London. From Dr. F. von Heyden (Nachfolger), Radebeul, Germany. Eng. Pat. 17,075, November 23, 1888. 4d.

THE methods hitherto employed for the preparation of *p*-hydroxybenzoic acid have been by heating potassium salicylate to 210° or by passing carbonic acid gas over potassium phenate at 200–220°, when the decompositions represented respectively by the following equations take place—

In both these reactions 1 mol. of phenol is liberated. According to the present invention the above operations are to be performed in closed vessels under pressure at 180 or upwards, when the whole of the product produced consists of a salt of *p*-hydroxybenzoic acid—

The potassium salt is then dissolved in water, and the *p*-hydroxybenzoic acid precipitated by means of a mineral acid.—T. A. L.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Prevention of Frilling. E. Himly. Phot. Arch. 30, 229.

IN order to prevent frilling, which is not uncommon with developers which contain potassium carbonate and especially caustic alkalis, the author coats the edges of the plates, before development, with a solution of india-rubber in benzene.—C. H. B.

Discolouration of Gelatino-Chloride Prints. Stolze. Phot. Wochenblatt, 15, 265.

In the various operations of developing, washing, &c., the gelatin film becomes soft and liable to injury. The use of the ordinary alum bath leads to a precipitation of sulphur and consequent discolouration of the image if all the thio-sulphate has not been removed, and the use of solutions containing much sulphurous acid is unpleasant. The author recommends immersion in a solution of chrome alum which has been carefully neutralised with ammonia.—C. H. B.

Observations on the Use of Coloured Glasses in Photography. Delaurier. Bull. Soc. Chim. [3], 1, 706—707.

LIPPMANN'S experiments to obtain photographs, representing the true value of light, remind the author of some fruitless experiments to obtain photographs in material colours by the action of light, using alternately three glasses, red, yellow, and blue. In these experiments it was observed that light, passing through an orange-tinted glass, produced a very even photogenic action of all subjects to be reproduced. It was found, however, that only the difference of luminous intensity acted and produced true images as to shade and light. When the orange glass was too thick or too thin, or too deep in colour, or too light, the action was naturally imperfect. But when once the right glass is prepared, very good photographs are always obtained. The author claims considerable advantages for his method over Lippmann's, as it is sufficient to put a glass of right colour and thickness either before the objective or before the aperture of the dark chamber.—A. L.

PATENTS.

An Improvement in the Method of, and Materials or Compound employed in Developing Photographic Pictures or Images. W. Oldham, Eton. Eng. Pat. 16,537, November 14, 1888. 4d.

THE ordinary materials used for alkaline development are mixed in the form of dry powders for convenience of transport and storage, and are dissolved in water when required for use. The proportions of the mixture may be varied according to circumstances, but the quinol developer may consist of quinol $3\frac{1}{2}$ parts, sodium sulphite $7\frac{1}{2}$ parts, potassium metasulphite $1\frac{1}{8}$ parts, sodium carbonate 12 parts. It is better to have two powders, one consisting of the sodium carbonate, and the other of the remaining ingredients, the proportions in the packets being those suitable for compounding the developer.—C. H. B.

Improvements in Photographic Negatives and Sensitised Plates for use in Photo-Illustrative Processes. H. Deveril and W. Gallagher, Sydney, New South Wales. Eng. Pat. 9921, June 17, 1889. 4d.

BEFORE or after exposure on the subject to be produced, the sensitive plate is exposed for a short time to a feeble light under a "mater," which is prepared by coating a transparent or translucent substance with opaque matter in such a way that it is transparent only in lines, dots, or grains. Such an image may be transferred from a lithographic stone, or the "mater" may be an ordinary photographic negative of a drawing or any other object which will give a negative of the character required. After the plate has been exposed on the object and under the mater it is developed, and the image is a composite of the image of the object and of the dots, lines, or grains of the mater.

An unvarnished gelatin negative is immersed for 10 to 15 minutes in a saturated solution of potassium dichromate, the excess of liquid blotted off, the plate dried in the dark, and then exposed to bright light until it becomes covered with opaque dots or grains owing to the reduction of the dichromate and combination of the chromic oxide with the gelatin. The plate is then washed and dried, and is used for printing a transfer in the usual way.—C. H. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Experiments Demonstrating the Mode of Action of Explosives. F. C. G. Müller. Zeits. f. d. Phys. u. Chem. Unterricht, 2, 170.

IN order to show the action which takes place between charcoal and saltpetre, 10 grms. of saltpetre and a piece of wood charcoal 1 gm. in weight are introduced into a large test tube fitted with a doubly bored cork. Through one hole of the cork passes a delivery tube; the other is plugged by means of a piece of glass rod. The saltpetre is now melted and that part of the tube containing the charcoal heated. The gases evolved are collected in a jar of about 2 litres capacity. In about one minute the whole of the carbon has disappeared and about 1.8 litre of gas has been collected. After absorption of the CO_2 by means of caustic potash only nitrogen remains, occupying about two-fifths of the original gas volume in accordance with the following equation:—

By now removing the glass plug and slowly adding water and dilute acid by means of a small funnel, carbonic anhydride is given off from the residue, and may be measured. The quantity of CO_2 obtained falls somewhat short of the theoretical quantity on account of mechanical losses, &c.

The immense gas evolution on explosion may be shown by supporting a tubulated bell-jar, of 1 to $1\frac{1}{2}$ litre capacity, on a tripod stand in a trough of water. The tubulus is fitted with a cork carrying a tube furnished with a stop-cock, and a piece of glass tubing sealed at the upper end and containing in its lower portion a piece of smoldering tinder. On the water inside the jar floats a piece of wood carrying 1 gm. of a mixture consisting of 8 parts of saltpetre, 1 part of sulphur, and 1 part of finely powdered wood charcoal. The air is sucked out of the jar until the wood rises to the tinder, which ignites the powder. The wood is driven down as far as the tripod, but in a few seconds as the gases cool their volume contracts to about 150 cc.

To show the action of nitroglycerol a sheet of lead 2 cm. thick and weighing about 2 lb. is placed on an anvil, and a small hole punched into it about 4 mm. in diameter and 6–8 mm. deep. If then 1 to 2 drops of nitroglycerol be introduced into the hole and the lead then struck directly on the hole with a tolerably heavy hammer, explosion ensues, and a cavity about 15 mm. in diameter is made in the lead.—T. L. B.

PATENTS.

Improvement in Fuses or Igniting Apparatus for Armour-Piercing Shells. A. Noble, Newcastle. Eng. Pat. 15,934, November 3, 1888. 8d.

THIS invention has for its object improvements in fuses or igniting apparatus for armour-piercing shells. The projectile is provided with an arrangement which, on striking the object, crushes a small glass vessel enveloped in lead and containing sulphuric acid. This acid is thus brought in contact with a charge of chlorate of potassium and sugar, which fires the shell. The ignition of this charge may be delayed by thickness of paper interposed between the acid and the chlorate mixture.

It is necessary, in order to clearly understand this invention, to refer to the drawing attached.—C. N. H.

Improvement relating to the Manufacture of Explosives and to Apparatus therefor. H. S. Maxim, Westminster. Eng. Pat. 16,213, November 8, 1888. 8d.

THE object of this invention is to produce a smokeless powder suitable for firearms, &c.

In carrying out this invention gun-cotton is treated with solvents such as acetone or a mixture of acetone and alcohol and ether in a vessel from which the air has been exhausted.

By this means the horny material produced is free from air bubbles, and becomes, after being subjected to a high pressure, very hard. It is then reduced to a granular or other suitable form.

There are 11 claims and two drawings of the apparatus used attached to this specification.—C. N. H.

Improvements in or relating to Percussion Caps or Fuzes.

H. M. Chapman, Waltham Cross. Eng. Pat. 16,997, November 22, 1888. 6d.

THE object of this invention is to effect the ignition of nitro-explosives known as "high explosives" in firearms, ordnance, and the like, without producing "detonation," which, as is well known, has frequently caused the bursting of guns.

In carrying out the invention the use of fulminates are dispensed with, and friction material, giving a longer flash and greater igniting power, substituted.

One of the compositions for charging the caps used with nitro-explosives, is the following:—

Amorphous phosphorus.....	15·90
Potassium carbonate	2·00
Powdered resin	2·00
" cane sugar	2·00
" mercuric oxide	4·00
" peroxide of manganese...	5·20
" magnesium	6·10
" potassium chlorate	10·90
" potassium nitrate.....	51·90
	100·00

but the above mixture is open to variation.—C. N. H.

Improvement in Mining or Blasting Cartridges and in Shells or Explosive Projectiles. P. Giffard, Paris, France. Eng. Pat. 12,089, July 30, 1889. 4d.

THIS invention relates to mining or blasting cartridges and to shells or explosive projectiles, and consists essentially in charging them with liquefied carbonic acid gas.—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

A New Continuous Extractor. A. Ungerer. Zeits. f. angew. Chem. 1889, 304—305.

MOST of the many apparatus for making extracts are inapplicable when it is desired to make extracts of volatile substances or of substances which would be decomposed by distillation or by warming. The annexed figure shows an arrangement by which the most concentrated extracts or tinctures of spices, or perfumes, &c. can be made without evaporation. A number of cylindrical glass vessels, *a, b*, are placed on a suitable stand one above the other, so that the tube of one vessel passes through a cork fitted into the mouth of the vessel below. From 6 to 12 of these vessels may be used one above the other. The stand consists of a board with pairs of projecting pegs placed at such distances that there is room for the cylinders between them. Boards having a horseshoe-shaped piece cut out on one side, are placed on these pegs, and serve to support the cylinders in their places. The material from which the extract is to be obtained is placed in these cylinders, a little asbestos or cotton-wool packing having been first inserted. The solvent is then allowed to run into the top cylinder, either freely or (in order to increase the pressure) through a long tube attached to the top. The liquid permeates the substance in the cylinder and runs through into the cylinder below, and so on to the bottom, where it is drawn off as the strongest

possible tincture. By adjusting the lowest stop-cock, the speed of flow can be properly regulated. The number of vessels and the speed of percolating should be so regulated that the tincture begins to flow from the lowest cylinder just when the contents of the top one have been thoroughly exhausted. As soon as the top cylinder is exhausted it is removed, the whole column of vessels raised up a stage, and a newly-filled vessel is added at the bottom. In this

way the process becomes continuous, and a concentrated extract can be made, except, of course, towards the end of operation. When alcohol, ether, and similar solvents are used, the liquid remaining in the vessels at the end of the operation may be recovered by emptying the cylinders and distilling off the liquid from the spent material, or steam may be blown through the column from the top downwards, when the spirit is driven out, and may be collected below fairly well separated from the condensed water. Samples of the tincture may be taken at various stages by double boring the corks and attaching a tube with a stop-cock, through which a portion of the extract may be drawn as required; or a three-way tap may be used with branch tube instead of the ordinary tap arrangement.—H. S. P.

On an Apparatus for Indicating the Presence of Carbon Monoxide. M. Rasine. Bull. Soc. Chim. [3], 1, 555—558.

THE principle of this apparatus is based on the property of spongy platinum to absorb carbon monoxide with evolution of heat. In the circuit of an electric current two metallic plates are interposed, which, when touching, close the circuit. A bent rod is arranged near these plates, and its extremity is placed at a certain distance but immediately above the end of the upper plate. A combustible thread is attached to the free end of the rod and to the free end of the upper plate. This thread, serving to keep separate the two plates, is surrounded by muslin containing a fragment of cotton-powder dusted over with spongy platinum. Carbon monoxide will burn the thread and establish an electric current and thereby ring a bell put in its circuit.—A. L.

Withdrawal of Test-Liquid from Extraction Apparatus.
J. Hertkorn. Chem. Zeit. **13**, 1117.

In order to remove small quantities of liquid with a view to ascertain when extraction is complete, the extraction tube is provided with a small lateral tubulus about 1 cm. below the level of the liquid. This tubulus is closed by a cork which carries a narrow tube with both ends bent at right angles, and lying in planes at right angles to each other. The bent end of the tube which is inside the extractor is placed vertically, and the open end projects above the level of the liquid. When liquid is to be withdrawn, the tube is turned through 90°, so that the end inside the tube lies horizontally below the level of the liquid, which then flows from the outer end of the tube. When the tube is turned back, sufficient liquid remains in the horizontal portion to prevent escape of vapour.—C. H. B.

Sodium Nitro-Prusside as a Test for Caustic Alkalis and Alkaline Earths. H. Brunner. Schweiz. Wochens. Pharm. **27**, 237.

NITRO-PRUSSIDE produces an intense yellow colouration with caustic soda or caustic potash, also with baryta water and lime water, whilst in the case of carbonates and bicarbonates, no colour reactions are noticeable. If caustic soda be added to an aqueous solution of sodium nitro-prusside until an orange colouration is obtained, and the whole be then shaken with alcohol, a dark yellow oil separates, which on standing solidifies to an orange-coloured

crystalline mass. The aqueous solution of this sodium salt gives coloured precipitates with metallic salts; with acids it gives a green colouration, becoming violet on exposure to the air, with final production of a blue precipitate.—T. L. B.

The Estimation of Nitrogen by Kjeldahl's Method.
F. Martinotti. Zeits. Anal. Chem. **28**, 415—421.

In the analysis of manures free from nitrates the author proceeds as follows:—1 gm. of manure is treated in a flask of 200—250 cc. capacity, with 2 grms. of mercury, and 20 cc. of a mixture of phosphoric anhydride and strong sulphuric acid (200 grms. P_2O_5 + 1,000 grms. H_2SO_4). The flask is heated on gauze to gentle boiling till the contents are clear, the temperature is then raised and the heating continued till the solution is almost colourless. A few crystals of potassium permanganate are then added, and the mixture again heated to boiling and allowed to cool. The contents of the flask are diluted, a sufficiency of caustic potash or soda added, and the ammonia distilled over into semi-normal sulphuric acid. In a table the author gives a number of comparative results obtained by Kjeldahl's and by Will-Varrentrapp's methods. The numbers yielded by Kjeldahl's process are as a rule slightly higher than those obtained by Varrentrapp's method. The author describes Jodlbauer's modification of the Kjeldahl method for the estimation of nitrogen existing as nitrates. In this process raw phenolsulphonic acid and zinc dust are added prior to the heating with acid. The results obtained are not at all satisfactory, as is shown by the following table:—

The low results obtained are chiefly due to the loss of nitric acid fumes during the digestion.

The author recommends a method in which the nitrates are first destroyed by evaporating the substance to dryness with ferrous chloride and hydrochloric acid. The remaining nitrogen is then determined in the usual way. The nitrates are estimated separately by Schlosing's method. The total nitrogen thus obtained agrees very closely with the results yielded by the absolute process.—H. T. P.

The Estimation of Nitrates by the Kjeldahl Method.
O. Foerster. Zeits. Anal. Chem. **28**, 422—427.

In the analysis of bodies containing nitrates by the Kjeldahl method, phenolsulphonic acid is added prior to digestion, in order to fix the nitric acid as a difficultly volatile nitro-compound. A little nitric acid, however, always volatilises so that the results come low. The author completely prevents this loss by the addition of sodium thiosulphate, which fixes the nitric acid as difficultly volatile nitrosylsulphuric acid, the reaction being as follows:—

A number of experiments were made with pure potassium nitrate in the following manner. A weighed portion of potassium nitrate solution was evaporated to dryness in a flask. 30 cc. of phenolsulphonic acid (containing 5—6 per cent. phenol) were then added for every gram. of potassium nitrate taken, and, without warming, the mixture was shaken till solution of the salt was effected. 1 to 2 grms. coarsely powdered sodium thiosulphate were then added at once, followed, when decomposed, by a sufficient quantity (10 cc. for every 15 cc. of phenolsulphonic acid used) of sulphuric acid, and 0.4 to 0.5 gram. mercury, the mixture being heated immediately after these additions. The time of heating required is about 1—1½ hours. Beyond this stage the process is the same as the ordinary Kjeldahl method. The following results were obtained:—

results were obtained, as will be seen from the following table:—

These small losses of nitrogen were found to be caused by the non-absorption of a trace of ammonia in the receiver. By using a bulb U-tube as receiver, almost theoretical

The Purification of Litmus. O. Foerster. Zeits. Anal. Chem. **28**, 428.

COMMERCIAL litmus of the best quality is extracted with alcohol, and then digested with water and the solution filtered and evaporated. The residue is redissolved in water, filtered, and the filtrate precipitated with absolute alcohol containing a little glacial acetic acid. The precipitate is collected on a filter and washed with alcohol, which removes a violet fluorescent colouring matter. The precipitate is redissolved in water and reprecipitated as before, and this process is repeated a third time. The residue is repeatedly moistened with alcohol, to remove the acetic acid. The precipitate is finally dissolved in water, filtered, precipitated with weak alcoholic ammonia, collected on a filter and washed with alcohol. After drying it is ready for use.

—H. T. P.

The Estimation of Ammonia by Distillation. W. M. Stein and P. W. Schwarz. Zeits. Anal. Chem. **28**, 428—431.

THE authors highly recommend the distillation apparatus, a drawing of which is given below. The steam from the distillation flask A passes into the bulb B, into which is fitted by means of an india-rubber stopper the glass tube c. This tube is slightly contracted at the lower end, and is bent sideways to prevent the entrance of alkali from A. The wall of the tube is pierced with three holes of suitable size. During distillation a little condensed water collects in B, which serves to wash the steam as it bubbles through. Any alkali which may be blown into the tube c, immediately runs

out again, since the side-openings equalise the pressure within the tube. The absorption apparatus consists of an Erlenmeyer flask D, fitted with a side tube *f*, which is filled with fragments of glass. The receiver holds about

250 cc. up to the bottom of the side tube, *i.e.*, sufficient for a distillation. The standard acid is introduced through *f*. The small quantity of acid which adheres to the broken glass suffices to retain any traces of ammonia which escape condensation. The titration is performed in the receiver itself.—H. T. P.

A Source of Error in the Separation of Manganese from much Lime, by means of Ammonium Sulphide. L. Blum. Zeits. Anal. Chem. **28**, 454.

IN the analyses of blast-furnace slags, containing a little manganese in presence of much lime, the author noticed that the highly-concentrated solution of the slag, when mixed with ammonium sulphide, deposited, after long standing (24–48 hours) besides manganese sulphide, a crystalline compound, which caused the results to come high. On closer examination this compound was found to be calcium thiosulphate. In cases where it is necessary to separate a little manganese from an excess of lime, it is therefore advisable to boil the solution with ammonium sulphide and filter at once.—H. T. P.

The Estimation of Carbon in Iron. L. Blum. Zeits. Anal. Chem. **28**, 450–452.

UNDER this heading L. L. de Koninck (this Journal, 1888, 457 and 693) recently published a paper in which he recommends the addition of silver sulphate to the retort containing the carbon residue, prior to combustion with chromic and sulphuric acids, in order to retain any traces of chlorine present in the carbon residue as silver chloride. The author finds this precaution to be quite useless, for the silver chloride first formed is decomposed by the sulphuric acid when heat is applied. A blank combustion was made, a quantity of silver chloride being added to the acid mixture in the retort. After the completion of the experiment, it was found that the potash bulbs had increased in weight by 0.2495 gm. owing to the absorption of the decomposition products of the silver chloride.—H. T. P.

The Precipitation of Magnesia. L. Blum. Zeits. Anal. Chem. **28**, 452–454.

MOHR recommends sodium ammonium phosphate, in preference to sodium phosphate, as a precipitant for magnesia, because, in his experience, precipitation takes place more quickly and more completely when the former salt is employed. The author, however, finds, in opposition to Mohr, that in the case of very dilute solutions of magnesia, the precipitate produced by sodium ammonium phosphate is of an exceedingly fine crystalline nature, requiring several days to settle completely, while if the solution be filtered before it is quite bright, it runs through the filter turbid. On the other hand, when sodium phosphate is employed, the precipitate settles in a few hours, and is easily filtered off. The precipitation is as complete as in the case of sodium ammonium phosphate.—H. T. P.

The Use of Kaolin-Balls and of Salet's Pipette in Gas Analysis by Bunsen's Method. N. Bunge. Zeits. Anal. Chem. **28**, 457–466.

FOR the introduction of liquid reagents into the absorption tube, porous balls of papier-mâché or coke are employed. Gypsum has also been used for the purpose, but balls of all these materials are difficult to make, and they easily break to pieces. The highly recommends bullets made of a mixture of kaolin and soot. The best proportions are—three parts of finely levigated kaolin to one of soot. They are dried at a moderate temperature and ignited till all the carbon is burnt off. The bullets thus obtained have a smooth surface and adhere tightly to the wire. Their porosity depends upon the amount of soot originally used. Balls made of 6 parts of kaolin and 1.2 parts of soot, absorb about 65 per cent. of water, those of 3 parts of kaolin and 1 of soot, take up 71 per cent. of water; and those of 2 of kaolin to 1 of soot absorb 113 per cent. water; but these are very fragile.

A drawback to Bunsen's method is the necessity of transferring gases from one tube to another. This operation requires some skill and the use of large quantities of mercury. This objection may be overcome by employing Doyère's mercury trough and Doyère-Salet's gas pipette. Salet's pipette permits this transference of gas to be performed with great ease. By its use the gas may be treated with reagents in an ordinary tube, the measurements being made in another tube, which thus has no chance of being soiled. The tubes must not, however, exceed 200 mm. in length. Long eudiometers, difficult to handle, can be done away with; for explosions can be made with ease and perfect safety in Salet's pipette, which need only be provided with an extra tap, and two fused-in platinum wires for the purpose.—H. T. P.

On the Volumetric Determination of Zinc. A. Voigt. Zeits. f. angew. Chem. 1889, 307–308.

THE author suggests the following method for volumetric determination of zinc, which is much less tedious than Schaffner's method, now usually adopted, and which gives fairly accurate results, so that it is very suitable for everyday use in zinc works, even if it be not sufficiently exact for buying and selling upon.

The method depends upon the precipitation of the zinc from an ammoniacal solution by a standard solution of potassium ferrocyanide. The sample to be tested (blende, silicate, zinc ashes, &c.) is dissolved in hydrochloric acid, oxidised with a little nitric acid, and from 100 to 150 cc. of water are added. To this solution are then added from 5 to 10 grms. of potassium tartrate, according to the quantity of iron in the sample, so as to keep the iron in solution. Ammonia is then added until the solution is just alkaline, a point which is easily observed by the change of colour of the liquid from yellow to white, and the volume is made up with water to about 250 cc. A standard solution of potassium ferrocyanide is then run in from a graduated burette whilst the mixture is continuously stirred. The end of the precipitations of the zinc is recognised by taking out a drop and mixing it, on a white plate, with a drop of acetic acid; the first formation of Prussian-blue indicates the end of the reaction.

The ferrocyanide solution is standardised by dissolving 46 grms. of the pure commercial salt in water, and allowing the solution to stand for a few days, filtering off any deposit, and making up the volume to a litre. 12.461 grms. of ZnO are then dissolved in hydrochloric acid, and made up to a litre. 10 cc. of this zinc solution are measured off in a pipette, diluted with about 150 cc. water, 5 grms. of potassium tartrate and a few drops of ferric chloride added, and then ammonia added until the liquid is alkaline. The volume is then made up to about 250 cc., as in the case of the samples, and the solution is titrated, making use of a drop of acetic acid on a white plate to bring out the Prussian-blue reaction. 10 cc. of the ferrocyanide solutions should be required for 10 cc. of the zinc solution; or 1 cc. of standard ferrocyanide solutions equals 1 per cent. of zinc.

Manganese interferes with the accuracy of the test, but the presence of lead is of no consequence. A number of determinations are given, and compared with results by the Schaffner method, showing a fairly close agreement.

—H. S. P.

Ammonio-cobaltic Molybdate, Tungstate, and Vanadate. The Separation of Cobalt from Nickel and of Cobaltic from Cobaltous Salts. A. Carnot. *Compt. Rend.* **109**, 109—112.

THE differences existing between ammonio-cobaltic salts and the corresponding cobaltous and nickelous salts are, as a rule, not sufficiently marked to permit of a method of separation being based upon them. This advantage is, however, found in the case of ammonio-cobaltic molybdate, tungstate and vanadate. When ammonium molybdate is added to a solution of cobalt, which has been converted into a purpleo-cobaltic salt by the addition of hydrogen peroxide, ammonia, and ammonium chloride, no change takes place. If the solution be now acidified with acetic acid, a voluminous peach-coloured precipitate is formed, which is almost insoluble in water. Dried at 100° C. it retains its colour and has the following composition—

When heated above 100° C. it assumes first a blackish-green and then a greenish-yellow colour, water, ammonia, and oxygen being given off at the same time. The ignited salt takes a lilac tint on cooling. Its composition is—

When heated to a dull red heat this salt is decomposed, black oxide of cobalt and molybdic anhydride being separated. Nickelous and cobaltous salts do not give a precipitate with ammonium molybdate, either in acid or alkaline solution, if sufficiently dilute.

For the separation of nickel and cobalt the author gives the following details. To a hydrochloric or nitric acid solution of the two metals, ammonia and ammonium chloride are added in excess, as well as a little peroxide of hydrogen. After a few minutes the solution is boiled till no more oxygen is disengaged. It is allowed to cool, neutralised with acetic acid and an excess of 3—5 cc. of acetic acid per 100 cc. of solution added. A solution of ammonium molybdate is then run in, as long as a precipitate forms. After settling the supernatant liquor is decanted off and the precipitate transferred to a filter and washed with water containing a little ammonium chloride. When dry the precipitate is removed from the paper as completely as possible and gently ignited. Its weight, multiplied by 0.1332, gives the quantity of protoxide of cobalt, and by 0.1048 the weight of metallic cobalt. When dealing with small quantities of cobalt it is well to redissolve the precipitate in ammonia and reprecipitate by the addition of acetic acid and a few drops of ammonium molybdate. The nickel is separated from the filtrate by boiling with caustic potash to expel the ammonia, and the nickel is obtained quite pure by redissolving the precipitate in acid and reprecipitating with potash and bromine.—H. T. P.

On a New Method for the Volumetric Estimation of Mercury, Silver, and Thallium by means of Iodide of Potassium. A. Carnot. *Compt. Rend.* **109**, 177—179.

To the solutions to be estimated nitric acid is added and then a little starch solution. A solution of iodide of potassium of known strength is run in, when the insoluble iodides of the metals are thrown down, which as soon as the slightest excess of the iodide solution has been added are decomposed by the nitric acid present, with the liberation of free iodine, which reacts with the starch, giving the characteristic blue colour. The process is not satisfactory in presence of free hydrochloric acid or alkaline chlorides.—S. G. R.

Determination of Oxygen in Water. Max Müller. *Chem. Zeit.* **13**, 1188—1190.

THE author points out the impossibility of ascertaining the quality of water by making a single oxygen determination, as is generally done, by bacteriological examinations, or by determination of the quality of organic matter present. A water may contain quite a large quantity of bacteria and a considerable amount of organic matter without being by any means an injurious water; whilst, on the other hand, many waters containing but small quantities of bacteria and very little organic matter may be totally unfit for use. If the quantity of oxygen in a water be ascertained, when the water is fresh, and again after the water has stood for several days out of contact with air, it is found in the case of good waters that the change in quantity of oxygen is very slight, while bad waters show a very decided falling off, or even total disappearance, of oxygen. The author's method of determining the oxygen is as follows:—A small quantity of pure manganous sulphate is dissolved in the water under examination, and several cc. of concentrated caustic soda or caustic potash solution are added, air being carefully excluded. The manganous hydrate at first thrown down as a white precipitate, is immediately acted on by the free oxygen in the water with formation of one of the higher oxides. By adding now a little concentrated hydrochloric acid containing potassium iodide (air being here also carefully excluded), a quantity of free iodine is obtained corresponding to the free oxygen originally contained in the water. The free iodine may then be titrated with sodium thiosulphate. The whole process may be represented thus:—

Two drawings of a convenient form of apparatus for carrying out the process are represented in the figure.

A bottle of 2 to 3 litres capacity is fitted with a doubly-bored cork, carrying a 25 cc. tap funnel, and a small tube bent once at a right angle. The stem of the tap funnel passes some distance into the bottle, whilst the end of the

other tube is flush with the inner surface of the cork. A rubber tube connects this outlet tube with a wider moveable tube, as shown. The bottle is filled to overflowing with the water under examination, and a crystal of manganous sulphate (about 1 grm.) is then introduced; all air is displaced from the rubber tube by means of water, and the cork is quickly inserted. By raising the side tube and carefully opening the stop-cock of the funnel, all air is displaced from the stem of the funnel. Five cc. of a strong caustic soda solution are now introduced into the tap funnel and drawn into the bottle with the aid of the moveable tube. The precipitate formed is well agitated, and, after the lapse of about half an hour, the funnel may be rinsed with water, and about 15 cc. of hydrochloric acid, with a few crystals of potassium iodide dissolved therein, are added as before. After complete solution of the manganese oxides, the whole contents of the bottle are transferred to a porcelain dish and titrated with sodium thiosulphate solution. By working with several bottles, a number of determinations may be very expeditiously made. If the water contain nitrites, of course a sample must be treated with HCl and KI, and titrated with sodium thiosulphate in order that the necessary subsequent correction may be made.—T. L. B.

The Behaviour of Wood and Cellulose at High Temperatures in Presence of Water. H. Tauss. Dñgl. Polyt. J. 273, 276—285.

See under XIX., page 913.

The Reactions of Oils with Nitrate of Silver. R. Brullé. Compt. Rend. 109, 118—119.

TEN cc. of oil are heated in a porcelain capsule with 0.5 cc. of fuming nitric acid. The mixture is violently agitated till a kind of cream is produced, when 5 cc. of a solution of silver nitrate in 90 per cent alcohol (25 grms. per 1,000 cc.) are added, and the heating continued. As soon as the temperature reaches about 115° C., the silver nitrate is briskly decomposed, with separation of silver. The heating must be continued till the film of silver first formed disappears. If the oil be now examined by transmitted light, by spreading it over the side of the dish, it will be found to have assumed a very characteristic tint, depending on the nature of the oil. The play of colours on the surface, as seen by reflected light, is also very characteristic. If the oil be saponified prior to the above treatment, the colours obtained are quite different. In the following table the colours yielded by different oils are given:—

COLOURS OBTAINED.

Oil Used.	In the Natural State.		Saponified.	
	By Transmitted Light.	By Reflected Light.	By Transmitted Light.	By Reflected Light.
Olive	Olive-green.	Green.	Orange (Orangé de Mars).	Cyprus-green.
Cotton.....	Green.	Asby-green.	Sienna.	Cobalt-violet.
Sesame	Chrome-yellow.	Bright Sèvres blue.	Golden-yellow.	Cobalt-violet.
Earth-nut	Greenish-yellow.	Emerald-green.	Persian lake.	Bright violet.
Poppy	Olive-green.	Bluish-green.	Golden-ochre.	Blue.
Camelina	Persian lake.	Bright blue.	Dark chrome.	Blue.
Linseed.....	Dragon's blood.	Emerald-green.	Black.	Green.
Colza	Persian lake.	Cyprus-green.	* Burnt carmine.	Ultramarine blue.

* On cooling, blue crystalline needles separate on the surface of the liquid.

With a little practice, it is easy to determine the presence of 5 per cent. of a seed oil in olive oil by means of the above test.—H. T. P.

On a Method for detecting Impurities in Alcohols by Potassium Permanganate. P. Cazeneuve. Bull. Soc. Chim. [3], 1, 700—702.

THE author uses as standard a chemically pure alcohol of 93°. The reagent is a solution of potassium permanganate of 1:1000. 10 cc. of the pure alcohol require, at the ordinary temperature of 15°—20° C., 1 cc. of the permanganate solutions to produce a colouration that will last five minutes. If it be decolourised in less time impurities are indicated. To examine dilute spirits, such as brandy, it is best to proceed in the following manner:—500 cc. of the liquor are distilled in the apparatus of Le Bel and Henninger, containing four bulbs. The first 10 cc. are tested in the same way as already specified, and compared with the chemically pure alcohol. This distillate will contain impurities, such as aldehyde, acetone, &c. The distillation is continued until only a few cc. remain, and these are tested as well. Bodies like furfural will be thus discovered.

The author contends that his method is superior to the sulphuric acid method of Bang.

Of course this reaction only proves that the alcohol contains impurities, it does not give information as to their character.—A. L.

The Estimation of the Extract in Wines by the Indirect Method. E. Egger. Zeits. Anal. Chem. 28, 397—404.

THE estimation of the extract of wines is generally performed as follows:—50 cc. of the wine are evaporated in a platinum dish on the water-bath. The residue is heated for 2½ hours in a water-oven and weighed. In the case of sweet wines, less than 50 cc. must be taken, and in no case must the dried residue exceed 1—1.5 grms. in weight. The author condemns the indirect method of estimating extract. By this process the extract is deduced from the density of the wine, freed from alcohol, and diluted to the original bulk. In a table the author gives the extract numbers obtained in the analysis of 150 samples of wine by both methods, the indirect values being deduced from the density by means of the tables constructed for the purpose by Schultze and

Hager. The differences observed between the indirectly and directly obtained results were as follows:—

Difference.	According to Schultze's Tables.	According to Hager's Tables.
Less than 0.1 grm.....	In 71 cases	In 2 cases.

„ 0.6 and 0.7 „ ..	„ „	„ 3 „
„ 0.7 and 0.8 „ ..	„ „	„ 1 „

According to Schultze, the results are in 32 cases higher than the direct numbers, in 122 cases lower than the direct numbers, and in six cases identical with them. By Hager's tables, the results, with one exception, were found lower than the directly determined values. A wine containing less than 1 grm. of solids per 100 cc., after subtracting the free acids from the extract, is to be regarded with suspicion. For this reason at least 26 of the 150 samples examined by the author would be condemned if the extract as found by Hager's tables be accepted as correct.—H. T. P.

The Quantitative Estimation of Galactose. E. Steiger.
Zeits. Anal. Chem. **28**, 444—450.

THE author has constructed a table similar to those used for dextrose, &c., by means of which the quantity of galactose corresponding to a given quantity of copper can be found. The necessary gravimetric sugar estimations were carried out as follows:—60 cc. of Fehling's solution were placed in a beaker of about 300 cc. capacity, diluted with 60 cc. of water, and raised to the boil. 25 cc. of galactose solution were then added, and the mixture boiled for 3—4 minutes. The precipitated cuprous oxide was filtered off on a Soxhlet asbestos filter, washed and reduced in a current of hydrogen. A distinct increase in the quantity of copper was observed when the time of boiling was prolonged to 30 minutes; on the other hand, seven minutes boiling had no appreciable effect on the amount of metal obtained. From the results of these experiments the following table was calculated:—

Yield.		Yield.	
Galactose.	Copper.	Galactose.	Copper.
Mgrm. 250.0	Mgrm. 434.5	Mgrm. 125.0	Mgrm. 232.7
237.5	411.8	112.5	211.1
225.0	393.6	100.0	188.7
212.5	375.0	87.5	165.4
200.0	354.2	75.0	142.4
187.5	335.0	62.5	120.2
175.0	316.4	50.0	94.8
162.5	297.6	37.5	73.1
150.0	277.5	25.0	49.9
137.5	254.9		

—H. T. P.

Combinations of Oxide of Copper with Amalgaceous Substances, Sugars, and Mannites—New Reagents for their Direct Analysis. C. E. Guignet. Compt. Rend. **109**, 528—530.

A SOLUTION of cellulose in cuprammonium hydrate is precipitated by addition of a large quantity of water, and gives a definite compound of cellulose and oxide of copper, which gives up all trace of ammonia by prolonged washing. Amidon or starch readily absorbs cupric oxide and ammonia from cuprammonium hydrate, completely decolourising the blue liquor. The compound produced yields only the merest trace of copper on prolonged washing with water or ammonium hydrate. It is of a deep blue colour, but when heated with water to 40° C. it loses ammonia and turns to a green colour. At 80° C. the compound passes to the condition of a paste and retains anhydrous cupric oxide intimately mixed with the starch. By prolonged digestion of the above with pure ammonium hydrate a liquor is obtained containing soluble starch and cupric oxide in solution. Inulin behaves in an analogous manner. Cuprammonium hydrate does not precipitate any of the sugars, but the case is different with ammoniacal copper sulphate which does not contain excess of ammonia. This compound is produced by gradually adding to caustic ammonia pulverised sulphate of copper dried at 100° C. The mixture is boiled and allowed to cool.

Cane sugar and milk sugar have no effect on ammoniacal cupric sulphate, whilst pure glucose (from honey), galactose, &c., precipitate the reagent after a few minutes. Invert sugar prepared by action of weak sulphuric acid on cane sugar gives no reaction, nor does pure levulose. If, however, glucose be added to invert sugar or levulose the glucose compound is precipitated after several hours, which seems to indicate that invert sugar is a true compound and not a mixture of glucose and levulose. The compound of glucose and copper oxide thus obtained contains no ammonia and is soluble in water or ammonium hydrate. The ammoniacal solution is decolourised on heating without any deposition of cuprous oxide and with the formation of a soluble ammonia salt having the properties of gluconate of ammonia. This fact indicates that in the estimation of glucose by a bitartrate solution of copper we ought not to add ammonium chlorhydrate as is sometimes recommended, for in the presence of free ammonia a little glucose may escape detection.

Mannite and dulcite produce with solutions of ammoniacal cupric sulphate a blue precipitate, soluble in ammonia, to a blue solution which is not altered by boiling. Vegetable acids, gums, pectic bodies, and most other substances contained in decoctions of vegetable materials do not precipitate ammoniacal cupric sulphate, hence this body is a useful reagent for separating the carbohydrates from such decoctions. The authors have obtained well crystallised mannite from the copper precipitate obtained from a decoction of sea-weed (wrack) and from the juice of mountain-ash berries. The copper compound is decomposed by sulphuretted hydrogen, the sulphide of copper removed by filtration and the filtrate evaporated and extracted with weak alcohol.—A. J. K.

The Analysis of Etheral Oils. R. Benedikt and A. Grüssner. Chem. Zeit. **13**, 1087—1088.

A. KREMEL recently observed (Pharm. Post 1888, **21**, 789, 821) that the usual quantitative reactions employed in the analysis of fats may also perform important service in the analysis of etheral oils. He has accordingly estimated the acid-, ester-, saponification- and iodine values of a large number of etheral oils.

It is also possible to obtain valuable evidences in the identification, valuation, and discrimination of purity of the etheral oils as well as recognition of impurities, by examining these oils by the method devised by Zeisel for the estimation of methoxyl in organic compounds, since a whole series of oils contain substances in admixture, possessing the constitution of methyl- and ethyl-ethers of phenols or acids, and, therefore, on boiling with hydriodic acid, furnish alkyl-iodides. The authors propose to express

the amount of alkyl radicles separated by hydriodic acid by the "methyl-number," which indicates therefore how many milligrammes of methyl I grm. of the substance loses on being boiled with hydriodic acid. In this case ethyl, propyl and isopropyl are considered to be replaced by their equivalents of methyl, effected according to Zeisel's method by calculating into methyl the amounts of silver iodide obtained, in each case. Thus, 0.2963 grm. of oil of cloves gave 0.3737 grm. of AgI. This multiplied by 15, the weight of the radicle methyl, and divided by the mol. weight of AgI = 235, gives 0.02385 grm., the weight of methyl equivalent to the silver precipitate, or calculated for 1 grm. of clove oil = 0.0805 grm. Hence this oil of cloves possesses the methyl-number 80.5. The apparatus used has been already described in this Journal, 1889, 735, with the method adopted, and so now it is only necessary to give some account of the methyl-numbers of the ethereal oils. The samples of oils examined were just the same as those examined as to other quantitative reactions by Kreml. Though a tabulated list of

methyl-numbers is subjoined, still many more samples must be tested before it is possible to estimate the limits between which the numbers vary. In the cases of a large number of oils there is no methyl-number, whilst with others only traces of silver iodide precipitates were obtained. These are indicated in the table by cyphers. Of course only oils free from alcohol can be tested by the method, and on the other hand, when once the methyl-numbers of the oils are known, the amounts of alcohol present can be estimated in them. Absolute alcohol possesses the methyl-number 326. The presence of oils containing sulphur is indicated by a black precipitate in the silver solution. In such a case the mere weight of the washed silver precipitate yields no result of value. Oils containing ethers of higher alcohols, such as butyl-, amyl-, and hexyl-alcohol, are recognisable in that the liquid above the silver precipitate will not become clear even after heating the oil for many hours with hydriodic acid, since small quantities of alkyl-iodides are continually distilling over.

No.	No. in Kreml's Table.	Name.	Methyl-Number.	Remarks.
1	1	Ol. Absinthii.....	0	Hänsel's patent oil.
2	2	Ol. Amygdalar. amar.....	0	From bitter almonds.

48	116	Ol. Pulegii	0	"Poleyol," Sch. and Co.
49	120	Ol. Rosmarini	0	Hänsel's patent oil.
50	124	Ol. Sabinae	0	Juniper oil of M and O.
51	125	Ol. Salviae	0	Oil of sage, Sch. and Co.
52	126	Ol. Santali	0	East Indian sandalwood oil, Sch. and Co.
53	128	Ol. Santali	0	West Indian sandalwood oil, M and O.
54	133	Ol. Terebinthinae	0	French oil of turpentine, Sch. and Co.
55	136	Ol. Terebinthinae	0	Austrian oil of turpentine.
56	137	Ol. Terebinthinae	0	American oil of turpentine, Sch. and Co.
57	141	Ol. Valeriana	0	Valerian oil, Sch. and Co.

The methyl-number gives direct indication of the value of some oils. For example, from the methyl-number can be calculated—

1. The Amount of Eugenol—

in oil of cloves, oil of cinnamon leaf, oil of cinnamon root, and in Ceylon oil of cinnamon. Thus there are contained in the following from the table already given:—

No.	Name.	Methyl-Number.	Eugenol.
			Per cent.
13	Ol. Caryophyllorum (Eugenol of Sch. and Co.)	88.8	97.0
14	Ol. Caryophyllorum (Hänsel's patent)	86.9	94.0
15	" " (Clove oil)	73.8	80.6
20	Cassia flor. (Hänsel's oil)	6.7	7.3
21	" foliorum (Cinnamon leaf oil).	73.2	80.0
22	Cinnamomi (Ceylon oil of cinnamon).	25.7	28.1

2. The Amount of Anethol—

in oil of anise, oil of star anise, and oil of fennel.

No.	Name.	Methyl-Number.	Eugenol.
			Per cent.
5	Ol. Anisi (Sch. and Co.)	82.8	81.7
6	" (Hänsel's patent oil)	79.8	78.7
7	Ol. Foeniculi (Hänsel's patent oil) ...	65.7	64.8

3. The Amount of Apiol, $C_{12}H_{14}O_3$, in oil of parsley. For this the methyl-number of pure apiol must first be determined.

Automatic Evaporating Apparatus. F. E. Ray. Pharmaceutical Record.

THE author describes an apparatus, which he has designed, for checking evaporation when it has reached a desired point. It is represented in the following illustration, which speaks for itself:—

The evaporating dish is counterpoised by sand placed in the bucket; then the weight to which the liquid is desired to be evaporated is counterpoised by an additional quantity of sand. The elastic band and the string to the gas tap are then arranged and heat applied. When the liquid has evaporated to the desired weight the falling of the sand bucket causes the closing of the gas tap, and the elastic band swings the dish away from the sand bath.

PATENT.

Improvements in the Means of Determining the Percentage of Fat in Milk. N. G. K. HUSBERG, Arboza, Sweden. Eng. Pat. 16,697, November 17, 1888. 6d.

THIS is an apparatus for the above purpose, and consists in a syringe-shaped instrument in which the milk and the chemicals (ether and alcohol) are mixed and the fat separated. The syringe is connected with a fine tube, into which the separated fat is forced and measured. Drawings accompany the specification and illustrate the construction of the instrument.—W. M.

New Books.

THE YEAR BOOK OF COMMERCE. Edited by K. B. MURRAY. Cassel and Co., London.

THE new Year Book of Commerce is an 8vo. volume, price 5s. It is compiled under the authority of the London Chamber of Commerce, is projected on the most useful lines, and contains a multitude of statistics arranged so as to be easily accessible and to carry their lessons at once to the reader. The tables of international trade contain in themselves a lesson, and inculcate a further lesson in the art of studying statistics profitably. Amongst other things, it is shown that the United Kingdom takes thirty-two per cent. of the entire exports of Russia, a circumstance worthy of consideration when our political attitude towards Russia comes under discussion. On the other hand, of Russian imports only 23 per cent. are drawn from the United Kingdom, and here Germany leads us. Thus, though we may not have less to lose than Russia through war, we should not be unmindful that Germany heads us in the supply of manufactured articles to Russia, and that we cannot afford to risk an inward trade from Russia amounting in 1887 to some 19 millions sterling, especially as so much of it is represented by food, wood, and other elementary products upon which life itself depends.

Again, though proximity has much to do with the volume of the trade transacted between two countries, in many cases it would be fallacious to conclude that a near neighbour is likely to be a good customer. Thus, Norway is closer to us than Sweden, yet we take only 7 per cent. of Norway's exports and 47 per cent. of Sweden's. Also, Germany takes only 35 per cent. of Denmark's exports, whilst we take 50 per cent. France is the country which most cultivates its immediate neighbours, and is far ahead of us and of Germany both as a buyer from, and seller to, Belgium, Spain, and Italy.

Germany is a seller rather than a buyer, so far as Europe goes, and in every case, save that of Belgium and that of Italy, it sends a greater percentage of the goods imported than it takes of the goods exported by the various countries. We occupy the converse position, with the exception of Italy. We take only 8 per cent. of what Italy has to sell, but send 19 per cent. of what she requires to buy.

There might be room here for our importers to cultivate Italy a little. Between the quinquennial periods, 1871—75 and 1875—80, the falling off in Italian exports to us was 15 per cent.; between 1875—80 and 1881—85 it was 19 per cent., but comparing 1887 with 1886 there was a growth of 11 per cent. At the same time, Italy was materially increasing the percentage of British goods in her importation, and though the onus of extending the export trade should lie with Italy, it is not certain that importers here might not legitimately, and with benefit to themselves, try to discover if there are no products now obtained elsewhere which might not be got as good and more cheaply from Italy.

DIE FARBEN INDUSTRIE. Viertel Jahrsbericht über die Leistungen auf dem Gebiete des Steinkohlentheers, der Chemie der aromatischen Verbindungen, der Künstlichen Farbstoffe, der Färberei, Bleicherei, des Zengdruckes und der Appretur. Im Verein mit fachkundigen Mitarbeitern herausgegeben von E. BERNSTEIN, Erstes Heft, October bis Dezember 1888. Berlin: Mayer and Müller, Markgrafenstr. 51. London: H. Grevel and Co., 33 King Street.

LARGE 8vo. pamphlet in paper cover. The price of the four numbers, Hefte 2 to 5, for 1889, is 2s.

The manner in which this subject is treated in this new quarterly journal, is made clear by a glance at the sub-divisional headings, which are as follows:—I. COAL TAR. II. AROMATIC COMPOUNDS. A. GENERAL. 1. Physical. 2. Physiological. 3. Theoretical. B. SPECIAL. Benzene Group. Diphenyl Group. Phenylated Fatty Hydrocarbons. Indol Group. Quinoline Group. Naphthalene Group. Phenanthrene Group. Anthracene Group. III. MORDANTS and DYE-STUFFS. IV. BLEACHING, DYEING, CALICO PRINTING and FINISHING. 1. General. 2. Preparatory operations. 3. Dyeing, printing, finishing. The present number (No. 1) commences with editorial preface, in which the necessity for such a collective quarterly periodical is claimed, considering the numerous discoveries of suggestive character, new colours or compounds possessing marked physiological influence, patents taken out by the physiologist, colour chemist, dyer, and calico printer, now being continually placed before the world.

The number contains 104 pages of text, and no pains appear to be spared to do the fullest possible justice to the theoretical as well as the practical side of the entire subject.

CHEMIKER-KALENDAR, 1890. Ein Hilfsbuch für Chemiker, Physiker, Mineralogen, Industrielle, Pharmaceuten, Hüttenmänner, u.s.w., mit einer Beilage. Von Dr. RUDOLF BIEDERMANN. Elfter Jahrgang. Verlag von Julius Springer, Monbijou-Platz, 3, Berlin. N. H. Grevel and Co., 33, King Street, Covent Garden, London.

SMALL 8vo. volume, in pocket-book form, price 3s., containing: Table of Contents; Chronological Table of important Occurrences and Discoveries during the Christian era, relating to Chemical and Physical Science; Calendar, with blank pages for notes; Table of more-frequently used Atomic Weights. After the Calendar follow some 28 pages of blank ruled paper for memoranda, &c. Next is a complete series of Tables supplying every want of the chemist which tabulated matter can supply. A good example of an amount of useful and valuable information condensed into a small space is to be found in the little chapter on the Investigation of Clays by Mechanical and Chemical means, and also of Fire Clays, the chapters mostly tabulated, on the detection and testing of the Coal-tar and Natural Colours, are also models of their kind. The work closes with a few pages ruled for the record of names and addresses, fly-leaves at the end supplying the German Post Office Regulations, and a complete railway map of the German Empire. The text fills 315 pages, a small volume in paper cover forming an Appendix to the Calendar—the "Beilage" referred to in the heading. In this are to be found tabulated matter for physicists, and at the end an Appendix, giving information as to the Professors and Dozenten in the various Polytechnic Schools and Universities, and to the subjects taught in those Institutions. A tabulated list is added of the prices of the various kinds and sizes of the more important articles of chemical apparatus.

HANDBOOK OF CHEMICAL TECHNOLOGY. Compiled and edited in association with several scientific men and specialists by Dr. P. BOLLEY, late Professor of Chemical Technology in the Swiss Polytechnikum in Zürich. Subsequently continued by Dr. K. BIENBAUM, Hofrath and Professor of Chemistry in the Polytechnikum of Karlsruhe. First volume of Group III. THE CHEMICAL TECHNOLOGY OF FUELS. By Dr. FERDINAND FISCHER. Brunswick: Friedrich Vieweg und Sohn. London: H. Grevel & Co., 33, King Street, Covent Garden.

THIS important work on the Chemical Technology of Fuel is contained in two volumes, Part I. and Part II., of which

Part I. was issued in 1880, and Part II. in 1887. They are of 8vo. size, enclosed in paper covers, and the price is 13s. The work is fully illustrated with 281 finely executed wood engravings, Part I. with 119 and Part II. with 135.

Part I. (1880) contains 160 pages of subject-matter, whilst Part II. (1887) contains 245. The whole work is devoted to methods of investigation, and these are headed as follows:—Measurements of Heat; Measurements of Light; Investigations of Fuels; Investigation of Atmospheric Air; Investigation of Fuel Gases; Investigation of Illuminating Gas. Under the investigation of Fuel is to be found a very complete and full description of the various calorimeters which have been devised; under that of Atmospheric Air, descriptions of the methods for estimating ozone, carbonic acid, carbonic oxide, sulphuretted hydrogen, sulphurous acid, and ammonia; whilst under Fuel Gases and their investigation are given data for judging of furnace efficiencies, for calculating the losses of heat through the gaseous products of combustion and for instituting a research as to evaporation efficiency.

MINES. Summaries of the Statistical Information contained in the Reports of Her Majesty's Inspectors of Mines under the provisions of the Coal Mines Regulation Act, 1887; the Metalliferous Mines Regulation Acts, 1872 and 1875; and the Slate Mines (Gunpowder) Act, 1882. Also List of Inspectors and Inspection Districts, Forms of Returns, and Particulars of Examination Boards and of Examinations. (C.—5780.) Price 9½d.

In the introduction which precedes these summaries it is stated that under the Coal Mines Regulation Act, 1887, every inspector of a district, and under the Metalliferous Mines Regulation Act, 1872, every inspector is required to make an annual report to a Secretary of State, and these reports have to be laid before both Houses of Parliament.

In these reports the statistics of persons employed in and about the mines are prepared, and an account of minerals wrought under the Coal Mines Act is also given. A separate volume, entitled "The Mineral Statistics of the United Kingdom," is also prepared by the Inspectors of Mines. From the summaries there given it appears that:—

The number of persons employed in and about all the mines in the United Kingdom of Great Britain and Ireland, together with the Isle of Man, and inclusive of those employed on private branch railways and tramways, and in washing and coking coal on premises adjacent to or belonging to the mines (this latter information being an addition to previous summaries), amounted to 592,656, of whom 5,680 were females above ground.

The number of persons employed in and about all the mines, exclusive of those employed on private branch railways and tramways, and in washing and coking coal, was 578,417, of whom 5,357 were females, the aggregate increase being 10,391.

The total number of fatal accidents was 885, and the total number of deaths occasioned thereby 960, being an increase of 4 in the number of fatal accidents, and a decrease of 91 in the number of lives lost, compared with the totals of the preceding year. The summary shows also the ratio of fatal accidents and deaths to persons employed, the death-rate per 1,000 being 1·660 as compared with the higher ratio of 1·850 of the year 1887.

The quantities and kinds of mineral wrought in the different districts in 1888 amounted to 182,660,163 tons, of which 169,935,219 was coal and 8,635,032 ironstone, the rest being fire-clay, oil shale, and other minerals, being a total increase of 9,610,368 tons compared with the preceding year, the increase of coal being 7,815,407, and of ironstone 1,065,114 tons.

The occupation of persons employed in and about mines under the present and former Coal Mines Acts is now more than twice as safe as it was at the commencement of the inspection, the average ratio for the first 10 years ending 1860 being one death in every 245 persons employed, for the 10 years ending 1870 one death in 300, for the 10 years ending 1880 one death in 425, whilst for the present year it is one in 602, a much more favourable ratio.

The ratios of accidents and deaths to the number of persons employed and tons of mineral wrought in each of the districts were, in 1888:—222,185 tons of mineral wrought for every fatal accident, and 205,698 tons for every death, as compared with the lesser quantities, 208,494 and 173,919 tons respectively in the preceding year.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Classification of Articles in Customs Tariff.

Note.—Pond = 36 lb. avoirdupois. Gold rouble = 3s. 2d.

A despatch, dated the 24th October last, has been received at the Foreign Office from Sir R. B. D. Morier, Her Majesty's Ambassador at St. Petersburg, enclosing a translation by Mr. Consul Michell, of a recent notification of the Customs Department making the following classifications of articles in the Russian Customs Tariff:—

Zinc sheets, nickel plated, to be admitted under section 102, point 2, of the Customs tariff. Duty at 85 copecks gold per pond.

Magnesite in powder, to be cleared under section 135. Duty at 15 copecks gold per pond.

Azotic acid salt of barium and strontium, to be cleared under section 140, as chemical salts not specially mentioned in the tariff. Duty at 2 r. 40 copecks gold per pond.—*Board of Trade Journal.*

Customs Tariff.

The Russian Customs tariff for drugs and chemicals is about to be revised in a manner which will render the importation of certain articles almost impossible. On this occasion the move appears to be made especially with the idea of injuring Germany. The duty on ether, collodium, salicylic acid, and chloroform is to be raised from 6 roubles to 15 roubles; on sulphuric acid, from 22 copecks to 30 copecks; on tartar-emetic, from 26 copecks to 4 roubles (about 400 per cent.); stearin and similar tars from 1·20 to 2 roubles; borax and boracic acid, from 11 copecks to 240 copecks per pond. These are but a few examples of an increase which extends over the whole of the drug and chemical branches. The pond is equal to 36 lb., and the gold rouble (in which duties are payable) to 3s. 2d.—*Chemist and Druggist.*

Revised Customs Tariff.

The revised Russian Customs tariff, under which the duties on many articles, especially certain classes of machine-tools, dyestuffs, tanning materials, colonial goods, glass and earthenware, chemicals, and pharmaceutical preparations, are to be increased to such an extent as to amount to virtual prohibition of importation, will probably come into force at the close of the first quarter of 1890. A new feature in the tariff is the adoption of a scheme by which the present duties are preserved for a number of articles, with the proviso that they will be applicable to the lowest class of goods only, while for goods of better manufacture and superior quality the duties will be doubled or even trebled. It was at first thought that the new Customs law would be aimed specially against Germany, but, according to this particular "shoddy" clause, it would certainly seem as if Germany is to be exceptionally favoured, at the expense of such countries as Great Britain and France.—*Ibid.*

ITALY.

Prohibition of the Importation of Saccharine.

A communication, dated 8th October last, has been received from the Foreign Office, forwarding the following translation of an Italian decree, dated the 29th September last, by which the importation and production of saccharine and saccharine products in the kingdom of Italy are prohibited.

Art. I. The importation and production in the kingdom of Italy of saccharine (*benzoato solfinico*) and of saccharine products are prohibited.

Any person contravening or attempting to contravene this prohibition will be subjected to the penalties imposed for contraband.

The rules respecting the importation of saccharine for medical use will be fixed by ministerial decree.

Art. II. The present decree will come into force on the 1st October 1889, and will be presented to Parliament to be converted into law.

A despatch, dated the 15th October last, has been received from Mr. H. N. Dering, Her Majesty's Chargé d'Affaires at Rome, enclosing copy and translation of the regulations framed by the Ministry of Finance, in accordance with the decree printed above, respecting the introduction into the kingdom of saccharine for pharmaceutical purposes. The copy and translation in question may be seen on application at the Commercial Department, Board of Trade, S.W.—*Board of Trade Journal*.

QUEENSLAND.

Exemption from Duty of Sulphate of Ammonia.

The *Moniteur Belge* for the 5th October last states that, according to a recent decision, sulphate of ammonia intended exclusively for the manufacture of liquid ammonia is free from import duties in the colony of Queensland.—*Ibid*.

Foreign Import Duties on Salt.

See *Board of Trade Journal* for November, p. 507.

VICTORIA.

Tariff Alterations.

The revised Tariff Bill was passed in October, and by it all medicines are to pay a duty of 25 per cent. *ad valorem*. Medicines are defined as consisting of two or more ingredients mixed ready for use, not being in chemical combination; drugs and chemicals, packed ready for retail sale or consumption, including medical compounds, containing spirits not exceeding the strength of proof by Sykes' hydrometer; and all preparations recommended as beneficial for any portion of the human or animal body or the cure or the treatment of any disease or affection whatever; and medicine chests or cases, with or without fittings. Patent and proprietary medicines as such disappear from the tariff. Chinaware and porcelain (except photographic and telegraphic materials) is changed from 2s. 6d. per cubic foot to 15 per cent. *ad valorem*; earthenware, including packing (except the above materials), altered to 8d. per cubic foot, measuring outside the package as imported, instead of 1s. 4d. per cubic foot measured after the goods had been unpacked and stacked, and all breakages thrown out; bent and bevelled glass, instead of 1s. per cubic foot, is now 20 per cent. *ad valorem*; all bottles, including medicine bottles, are to be 6d. per cubic foot, measured outside the package, not the solid measurement of the bottles themselves; the duties on oils in bottles are doubled (4s. per dozen quarts and so on), and a new line has been introduced imposing 12s. per dozen on bottles of oil containing more than a quart, but less than a gallon; perfumery is raised from 10 to 20 per cent.; the duty on paper and cardboard boxes is now revised so as to cover paper or cardboard (with or without printing) cut into shapes for wrapping or boxing, and still stands at 25 per cent. Acetic acid, formerly 3d. per pint or lb., is now charged at that rate when containing not more than 30 per cent. of "acidity," and for every extra 10 per cent., or part of 10 per cent., above 30 per cent., 1d. per pint or lb.

Chlorodyne is classed as a drug at 25 per cent. *ad valorem*. *Cocculus indicus* is raised from 1s. 6d. per cwt. to 1s. per lb.; *nux vomica* from 1s. 6d. per cwt. to 2d. per lb., but with no corresponding increase on strychnine. Liquid glue, liquid gum, and cements are made 20 per cent. *ad valorem*; gold and silver leaf, 20 per cent.; inks, writing liquid or powder, 10 per cent.; leather (including split skins, &c.), 6d. per lb.; extracts of or concentrated meat, 20 per cent.; preserved milk, 2d. per pint or lb.

Duties have been removed from carbolic, oxalic, and pieric acids, aloes, *cannabis indica*, *faba amara*, grains of paradise, quassia, iodide and bromide of potassium, and syphon bottles, which are now free.—*Chemist and Druggist*.

FRANCE.

The Match Monopoly.

The French Ministry suffered a serious defeat in the new Chamber on the 21st November, on the question of the lucifer match monopoly. The Government accepted an Order of the Day in favour of its working the monopoly, but this was rejected by 312 to 236. The first clause of a Bill making the manufacture of matches a free industry was carried against the Government by 292 to 232; but 48 hours later the Bill was thrown out by a majority of seven.—*Standard*.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

THE MARGARINE TRADE IN SWEDEN.

A despatch, dated the 24th October last, has been received at the Foreign Office from Sir F. R. Plunkett, Her Majesty's Minister at Stockholm, respecting the Swedish decree relating to the manufacture of margarine. The following is a copy of the *précis* of some of the provisions of the new enactment concerning margarine forwarded to Sir F. Plunkett's despatch:—

The new law which has to-day appeared in print is intended partly to prevent margarine (by which the enactment comprehends every butter-like substance of whatever origin, mixture, or combination it may be, so long as it contains fat which is not produced from milk) from being offered for sale in Sweden, imported thither or exported thence, except under its proper name; partly to provide a control that the margarine which is made in the kingdom be prepared from adequate materials that are innocuous to health, and that the preparation thereof is conducted in such a manner that the article manufactured is not injurious to health.

On comparing it with the present Swedish margarine law, we find that the new enactment presents the following essential differences, viz., constant control of the manufacture; a prohibition of owners of dairies making margarine; certain shapes for the vessels in which margarine is to be kept; the expenses of testing being as a general rule defrayed from the public purse; the greatly increased individual responsibility.

From the brief account we have just given of the characteristics of the new law, it will be observed that it closely resembles the Danish law concerning margarine. In Denmark, however, there is no constant control during manufacture as proposed in Sweden, while on the other hand the Swedish law does not include the decrees laid down by the Danish law concerning the colour of margarine, and the highest percentage of butter which margarine, according to their law, may contain.—*Board of Trade Journal*.

SILICIAN SULPHUR.

(*United States Consular Reports, August 1889, p. 549.*)

The American Consul at Palermo states that compared with former years little brimstone is now exported from Sicily in consequence of the low prices which obtain, and it is feared by some that the industry may have to be abandoned in the near future.—C. G. C.

CHINA.

Drug Exports.

The exports of some of the principal drugs from the Chinese treaty ports in 1888 have been:—

	Star Anise.	Camphor.	Musk.	Galls.	Ess. Oils.	Blue-barb.
Piculs	6,532	3,893	27½	31,201	2,346	1,265
Value, H. taels	80,392	33,631	221,473	316,372	250,475	167,528

The Camphor Trade of Formosa.

Camphor is gathered in the interior of the island of Formosa by Chinese Government employes, and then is taken over at the town of Tawatutia by a Cantonese contractor at the rate of 12 dolrs. per picul of 133½ lb. The work of collecting is done partly by civilians and partly by soldiers, and without military protection to the workmen from the attacks of the savages little collecting could be done in the wilder and more productive regions. Hence, when the soldiers have to be drawn away on more pressing duties, the work amongst the camphor trees is stopped. In 1888 troubles with the aborigines in two different parts of the island have occupied all the available troops, deprived the contractor of the handsome profits he would have made had he received the usual supplies, when Formosa camphor in the Hong Kong market rose to 30 dolrs. per picul. When the new contractor took over the work at the end of 1887, he introduced strong cases with thick lead linings for the carriage of camphor. But recently it has come forward for shipment in the old large tubs, containing nearly four piculs, while the cases contained less than one. It is also said that since the trade became a Government monopoly, camphor has gained in purity by the exclusion of the gum of a species of rattan creeper with which it was adulterated before.

Opium.

With regard to the falling off of the imports of opium into China, our Consul at Chin Kiang states—"The prospects for the present year point to a considerable further diminution of the import of 1888. In my opinion foreign opium is doomed to become, within a very measurable distance of time, a mere expensive luxury, only used by connoisseurs and the very rich, just as the very choice vineyards of France are in Europe."

Packing Goods.

Special attention should be paid to packing, as goods are subjected to very rough usage on their way into the interior of China.

Ground-Nut Oil.

Ground-nut oil has made a first appearance as an article of export by steamer from Pakhoi in 1888. Instead of sending it as formerly, in bulk, by junks, a method is gaining favour of packing it in old kerosene tins and shipping it by steamer, which suggests that considerable development may be looked for in the export of this article. —*Chemist and Druggist.*

MAURITIUS.

Vanilla Exports.

The following were the exports of vanilla from Mauritius in the years 1886 and 1887, according to value and weight:—

	1886.		1887.	
	Quantity.	Value.	Quantity.	Value.
	Kilos.	Rs.	Kilos.	Rs.
To France	12,054	208,312	12,496	182,421
To United Kingdom	10,604	100,537	5,954	67,988
To other countries	234	3,200	51	530
Total	22,792	312,049	18,501	250,939

—*Ibid.*

JAPAN.

Drug Imports.

Among the articles imported into Yokohama last year (1888) the following were of pharmaceutical interest:—

	Quantity.	Value.
	Lb.	£
Western drugs and chemicals.....	..	129,944
Eastern " " "	20,941
Aniline dyes.....	290,789	45,752
Dyes and paints.....	..	29,013
Indigo.....	379,184	28,734
Logwood extract.....	1,644,393	36,669
Condensed milk.....	..	16,466
Oils and wax	20,938
Oil paints.....	894,720	11,027
Potash.....	51,658	17,568

—*Ibid.*

PERU.

Drug Exports.

The value of coca leaves exported from Peru in 1888 is returned at 369,361 soles, which represents about 730,000 lb., the price ranging locally from 25 to 30 soles per 50 kilos. The exports of so-called "crude cocaine" are placed at about 100,000 soles.—*Ibid.*

GERMAN CHEMICAL TRADE.

Consul Monaghan, of Mannheim, reports that Germany is exporting to all parts of the world all kinds of drugs and chemicals in a finished state. During the last year 232,800,000 marks worth, mostly raw material, came in, and 236,000,000 marks worth, mostly finished material, went out of the Empire. Seven per cent. of the Empire's entire trade was in these articles in 1888, as follows:—

	Imports.	Exports.
	Marks.	Marks.
Raw material.....	143,300,000	27,800,000
Manufactures.....	99,500,000	208,300,000

The table shows an import of five times as much raw material as export of the same, while the export of manufactured wares was more than double the import of the same. The amount and values may be better expressed in the following table:—

Description.	Imports.	Exports.
	Marks.	Marks.
Raw materials:		
Raw material for chemical purposes	65,200,000	7,700,000
Medicinal drugs	15,600,000	5,800,000
Resins, pitches (Hartz)	21,200,000	7,400,000
Tanning stuffs	24,100,000	1,200,000
Manufactures:		
Bases, acids, and salts.....	27,700,000	60,300,000
Ether, oils, medicines, perfumeries .	9,000,000	27,200,000
Explosives and combustibles.....	700,000	12,800,000
Colours	34,700,000	80,500,000

—*Chemical Trade Journal.*

MISCELLANEOUS TRADE NOTICES.

THE CONDITION OF SIBERIAN INDUSTRY.

The *Lecum Herald* for the 8th October last says that there has recently been published at St. Petersburg an interesting work concerning Siberia, in which the following remarks occur:—

Judging by the official publication, Siberian industry is still in a sad condition. This immense country has only 1,055 factories and works, with 7,163 workmen, and a production of little more than 13 million roubles. And what are these factories? Cotton, woollen, and flax mills are conspicuous by their absence. It is the tanneries, the tallow factories, and the shops for the dressing of sheep skins which predominate. Specialists of a more refined order are almost non-existent. Thus, there was in 1887, for the whole of Siberia, only one factory of chemical products, and it was small, its annual production being only 25,000 roubles. It was the same with the paper factories, the only one existing producing only to the value of 4,000 roubles. It should be stated that the two factories were both in Western Siberia. —*Board of Trade Journal*.

INFLUENCE OF TAXATION ON METHODS OF PRODUCTION.

THE FUTURE PROSPECTS OF THE SALTPETRE INDUSTRY IN TARAPACA.

Chem Zeit. 13, 1915.

The President of the Chilean Republic, in his speech at the opening of Congress on the 1st of June, spoke of the position of the saltpetre industry, and its relation to the country itself. It was the desire of the Government to increase the production and lower the price of saltpetre, and at the same time to give the industry a more national character. This it was proposed to do by dividing out the saltpetre districts, and offering them publicly for sale. A certain portion of the best beds, however, would be reserved for natives and none other, and should they sell, they must sell to natives only. The country could not, of course, be closed to foreigners, but by such measures as these the Government hoped to prevent the industry becoming merely a foreign monopoly.—T. L. B.

CINCHONA HISTORY.

The idea of acclimatising cinchona in the British West Indian Islands was conceived about 30 years ago, when the exploring party who had been sent to South America to obtain cinchona plants and seed for British India were instructed to send any surplus they might have to the Governors of Jamaica and Trinidad for experimenting purposes. In 1861, the year following the receipt of the seed, there were already 400 plants ready for planting out in the Jamaica Botanical Gardens. As the climate of Bath Gardens, where the first experiment was made, was unsuitable for the successful growth of cinchonas, they were tried at Cold Spring coffee plantation, at an elevation of 4,000 feet. There the climate and soil proved all that could be desired, and in November 1862, a plant of *Succirubra* cinchona had attained to the height of 44 in., with leaves measuring $13\frac{1}{2}$ in. long by $8\frac{3}{4}$ in. broad. The same plant, when two years old, measured 6 ft. in height, with ten branches, having a circumference of stem at base of $4\frac{1}{2}$ in.

The experience gained in these preliminary attempts paved the way for the larger enterprise undertaken by the Jamaica Government in 1868, from which date cinchona planting in the island took a fresh departure. A further supply of seed, consisting of *C. officinalis* and *C. calisaya*, was obtained from Ceylon. In 1886 the Government

cinchona plantations in the Blue Mountain district occupied 143 acres. For the purpose of encouraging the cultivation of cinchona by private enterprise, the Government plantations during the last few years have distributed 1,250 oz. of cinchona seed, 1,200,000 cinchona seedlings, and 469,000 cinchona plants.

Large shipments of cinchona bark were made from the Government plantations during the years 1879 to 1884, and the prices realised proved that the climate and soil of Jamaica were particularly well suited to the successful cultivation of cinchona plants. As much as 10s. per lb. was obtained for root bark of *C. officinalis*, while on large shipments the average price realised was 6s. 7d. per lb. All the various species of cinchona have been introduced to Jamaica, including the valuable *C. ledgeriana*.

About 2,600 acres have been taken up by private planters for the cultivation of cinchona in Jamaica, and the industry there is now well established. But as Jamaica was late in the field, and only now produces bark of sufficient age to be placed in the market, the planters are compelled to hold back their bark until there is such an improvement in the market as will justify regular shipments. This, it is hoped, will only be a question of time. Meanwhile two samples of Jamaica loxa bark, from trees six years old, grown on a private plantation at 5,000 feet, have been lately analysed by Mr. David Howard, and found to contain:—

	Quinine.	Cinchonidine.	Cinchonine.	Amorphous.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
1	2.23	0.44	0.04	0.51
2	1.74	0.57	0.06	0.55

In each case there was a trace of quinine.

The tests are thus very much what loxa bark of similar appearance from South America would give. It is rather a Chaguera than a Crispi or Uritusinga, which gives the richer yields that characterise the finest officialis from the Dodaketta plantations. The fine old South American HO loxa quills, which would now be worth in London from 2s. 2d. to 2s. 6d. per lb., are used by French pharmacists for flavouring liqueurs. They are said to give to the latter a bouquet which cannot be obtained with any other variety of bark, or even with loxa itself when grown in India, Java, or Jamaica. For this reason only the genuine South American loxa realises prices wholly out of proportion to its alkaloidal value. It is also said that common hard pitayo bark at 2d. to 3d. per lb. is used in Spain for giving a "body" to sherry wine.—*Chemist and Druggist*.

GERMAN EXPORT TRADE.

A report on the export trade of the German Empire for the first half of the current year shows a material decline in the export of all German textiles, and a still more serious decrease in iron goods, especially rails, wire, and pig iron, which between 1886 and 1888 declined nearly a half, and the first half of 1889 recovered only slightly. The latter seems to be affected most unfavourably by the tariff policy and "rings." In machinery, the export of locomotives and engines falls considerably short of 1886 as well as of 1888, while the export of other machinery also is less than 1888. Copper goods have constantly declined; lead and zinc have also decreased. The trade in chemicals is still favourable, especially tar colours and chloride of potash, and aniline dyes improve slowly. In sundry articles, which up to last year showed a steady advance, a great decrease is noticeable in 1889, such as glassware, leather, and leather goods. There are also decreases in the exports of alcohol, spirits, beer, and paper, while there is an increase in sugar. The total result is a certain stagnation in the export of industrial products, which in 1888 amounted to 2,337 million marks, and in 1889 to only 2,369 million, and a notable decrease in the last half year. In raw materials there is a steady decrease from 958 million marks in 1880 to 932 million in 1883 and 834 million in 1888.—*Ibid.*

MINERAL RESOURCES OF PERSIA.

Recent surveys have shown that the supply of coal in Persia is not restricted to one or two places, that the quantity is practically unlimited, and that at the pit's mouth it can be produced and sold for 5s. or 6s. a ton. At present coal is only worked at Hir, 40 or 50 miles from the capital, where the output each year is 15,000 tons. Iron is believed to be found in close conjunction with these Persian coal-fields, but at present only one mine near Teheran producing excellent ore and 70 cent. of metal is likely to be seriously worked. The Elburz range is also rich in this mineral—the ore producing from 25 to 60 per cent. of metal. Copper is found throughout the country, and was one of the chief exports from Gombroom 170 years ago. There is also abundance of lead in the Elburz mountains, and as there is a great demand for this metal in Russia, it is expected that a profitable trade in it can be carried on across the Caspian. Among the other mineral resources of Persia may be mentioned borax, manganese, asbestos, and mercury. Naphtha and petroleum have also been referred to, and as they are to be found in greatest abundance near the Karun they can speedily be turned to practical purposes. —*Ironmonger*.

SODA IN HUNGARY.

Soda ash and soda crystals are imported into Hungary in large quantities: in 1888, 9,094 tons; in 1887, 8,660 tons; and in 1886, 8,350 tons, although very large soda deposits exist in the country itself. Near Nagy-Böcskő, in the district of Marmaros, there are large soda works owned by a Swiss, Mr. Friedrich Müller, but these are by no means equal to the supply of the wants of the country. Most of the soda salts imported into Hungary come from Bohemia, Silesia, and Galicia. A considerable quantity is also purchased from England and imported *via* Trieste, notwithstanding there is a duty of about 11d. per lb. on foreign soda ash and crystals. —*Chemist and Druggist*.

QUICKSILVER IN RUSSIA.

From some additional information about the Russian quicksilver mines recently given by a Russian gentleman, it appears that a bed of cinnabar was discovered in 1879 by Mr. A. W. Minenkoff, a Russian mining engineer, in the Catherine-slaff Government district of Bakmouk, about three miles east from the railway station, Nikitoko, on the Koursk-Kharkoff-Azoff line. From want of sufficient means the mine was not worked until Mr. Alexander Auerbach, late Professor of the Imperial Mining Institution of St. Petersburg, obtained from the peasants of the village Zaizelf, the owners of the land, the right of exploitation in the beginning of 1885. He engaged Mr. Minenkoff for careful exploration during the summer. The results being satisfactory, Mr. Auerbach was lucky enough to raise the required capital (exceedingly difficult in Russia, especially for mining affairs), and formed "The Society for the Exploitation of Quicksilver, Alex. Auerbach and Co., in St. Petersburg." At the end of December 1886, all buildings, engines, &c. being ready, the works were started. The lodes discovered are from 21 to 49 ft. thick, running from east to west, with a dip of 50°. The quantity of ore proved by exploration is estimated to be about 194,000 tons, and, calculated at nearly 1 per cent. quicksilver, would produce about 1,900 tons of metal. The works delivered during 1887, 3,905 pounds, or 141,009 lb. of quicksilver; in 1888, 10,060 pounds, or 362,366 lb., but with the present number of furnaces the company will be able to treat annually 51,200 tons of ore, and on the basis of the present extraction of about 15 lb. of pure quicksilver to the ton of ore, the quantity produced for sale will increase up to 22,400 pounds, or 808,864 lb., per annum. The consumption of quicksilver in Russia being about 2,000 flasks of 84½ Russian lb., or 76½ lb., English, every year, the company can export nearly 18,000 lb., say 8,820 flasks, per annum. The cost price of 1 pound (36 lb.) of quicksilver is not quite 15 roubles (1l. 11s. 3d.), or per flask of 2 pounds 4½ lb. (76½ lb. English), 31.50 roubles (3l. 6s.), and, with the selling price between

7l. and 8l. per flask, there are good reasons to expect good dividends in the future. These are the first and the only quicksilver works in Russia. Their establishment and prime cost has been about 630,000l. —*Ibid*.

AN AMERICAN CHEMICAL SOCIETY.

Eng. and Min. Journal, 48, 333.

In the issue of the *Engineering and Mining Journal* for June 8th, 1889, we referred to the proposed formation of an American Chemical Society, a plan for which was to be discussed at the Toronto meeting of the American Association for the Advancement of Science. In accordance with this plan an afternoon was devoted to the consideration of the suggested organisation before the Chemical Section, and in the discussion Professors Barker, Reimsen, Clarke, and Prescott each took an active share. For the most part the gathered chemists evinced their desire for a national society, but the conservative expressions of opinion from certain of the older members led to the loss of the resolution recommending the continuation of the committee with instructions to draw up a plan of organisation; and subsequently a committee was appointed, with instructions to canvas the ground and report at Indianapolis at the next meeting. This committee consists of Professors Clarke, of Washington; Bolton, of New York; Hart, of Easton; Warder, of Washington; and Ellis, of Toronto.

That a national organisation of chemists is desirable is certain, and that it could exist, and hold the same relation to the chemical industries of this country as the American Institute of Mining Engineers does to the mining industries, is also true. To this end, it seems to us, that the plan followed by the Society of Chemical Industry in Great Britain is the best one to adopt, viz., a national organisation with local sections, holding its annual meeting in connexion with that of the American Association. A fear that a new chemical society was to be created has been expressed by the more conservative chemists, but in the minds of those who are most active in the matter, it is consolidation of those existing that is desired.

Let the American Chemical Society of New York, the Chemical Society of Washington, and the Chemical Section of the Franklin Institute appoint delegates to meet and confer, for the purpose of considering ways and means of consolidation. They should decide upon such points as the following:—

1. The establishment of local sections at Boston, New York, Philadelphia, Washington, Baltimore, and other large centres.
2. The date and place of meeting for the election of officers.
3. The preparation of a financial scheme, so that the cost of management should be equitably divided among the different sections.
4. The publication of a suitable journal.

The establishment of a National Chemical Society should come from united action of the existing Societies, and not from without.

FACTORY INSPECTION IN AUSTRIA.

The following information on the subject of factory inspection in Austria is extracted from the last report of the United States Consul at Prague:—

The law creating inspections of industrial establishments went into effect June 17th, 1883. It consists of 20 sections, and its main provisions are given in the following synopsis.

The Minister of Commerce is authorised to appoint, with the concurrence of the Minister of the Interior, the necessary number of factory inspectors in the different provinces, and a general inspector. He may also appoint special inspectors for certain branches of industry whose districts may comprise different provinces. Only persons having the requisite knowledge of business and speaking the languages which prevail in their respective districts may be chosen for the office of inspectors.

It is the duty of the inspectors to enforce the existing laws and regulations in regard to—

1. The arrangements and provisions to be made for protecting the lives and the health of operatives, both in workshops and dwellings.
2. The mode of employing workmen, the hours of work, and the periods of rest.
3. The registry of operatives, factory rules, payment of wages, and working men's certificates.
4. The instruction of apprentices in the trade.

When the inspector produces his commission, issued yearly by the chief administrative officer of the province, the factory owner or manager is bound to permit him to enter the shops and the dwellings of the operatives at all times, but in the night time only when the shops are running. The owner or manager has a right to accompany him during the inspection.

The inspector is authorised to put questions to any person employed on the premises on subjects within the scope of his official cognizance, if necessary, without the presence of witnesses, avoiding, as far as possible, any disturbance of the business.

If entrance is denied to the inspector, or information refused, or employes are prevented from giving the information asked for, or urged to make false statements, the owner or manager makes himself guilty of an offence punishable under the factory code, unless the ordinary penal code is applicable. When the inspector finds that the factory laws and regulations are neglected or violated, he is obliged to insist upon an immediate correction of the failings or abuses. Should it be refused, he has to notify the proper authorities in order to enforce compliance through regular official action, and such authorities must in their turn notify the inspector of their action, from which he has a right to appeal to a higher instance.

Whenever the health of the employes appears to be endangered through the methods used at any manufactory, the inspector may ask the proper authorities to secure the assistance of experts and physicians in making an investigation, and if the defects charged by the inspector are found to exist the expense is to be borne by the owners. It is further made the duty of the inspectors to assist the manufacturers in complying with the law, to mediate between the employer and the employed when differences arise, and to try his best to maintain good relations between them.

The inspectors are required to report yearly to the Minister of Commerce, containing a list of the accidents met with by the operatives in the discharge of their duties, with their causes, and with suggestions of such legislative or administrative measures as may be in the interest of both employers and employed.

The inspectors are bound by their oath not to divulge any information they may become possessed of concerning the business condition or management of different industrial establishments, and particularly all such information the secrecy of which is enjoined by the owners of factories. A violation of this rule, and the use of the acquired knowledge of such secrets for his own benefit, either during the term of office or after, is punished by imprisonment from three months to two years, unless the ordinary penal code provides severer punishment.

An inspector must not be engaged in any industrial business either himself or by proxy, or be employed in any capacity in connexion with such business. He is not allowed to accept compensation of any kind or nature from the employers or workmen, and is bound to refuse their hospitality if offered.

Fourteen inspectors of factories and a general inspector have been appointed under the law. During the first trial, voices were loud prophesying the certain failure of the institution. The manufacturers were mostly hostile to the system of inspection, trying to impede its workings, and workmen were dismissed in some cases for bringing their grievances before the inspectors.

In regard to the enforced reduction of the hours of work from 12 to 11, it was asserted that it would cripple Austrian industry in its struggle with foreign competition, but evil

prophecies have not been fulfilled, and the system of factory inspection has by this time become popular even with the employers of labour.

The first annual reports were made in 1885, and the reports for the 1888 have recently been published. From the latter it appears that the factory inspectors have prevented many a strike, caused the redress of numerous just grievances, and brought about the adoption of measures in many factories for the protection of the operatives against accidents and injury to health.

In the course of last year the factory inspectors received 2,780 applications for advice, assistance, intervention, and mediation from factory operatives, and 1,350 applications from employers. They intervened successfully in favour of the operatives in 1,785 cases, and refused 757 such applications as not being well founded. During the same time the inspectors rendered opinions in 3,490 cases, and took part in 1,590 commissions and investigations. The number of orders and directions given by them in regard to better arrangements, ventilation, heating, lighting, &c., exceeds in the same period 10,000. The number of factories and shops inspected by them was 4,068, as against 4,190 during the previous year, with 270,000 operatives. There are in this Empire about 370,000 establishments subjected to the supervision of those officers, and since the creation of the present system of inspection until the close of last year there were 16,000 premises inspected. Hence it would appear that the number of inspectors is far too small for a comprehensive and thorough working of this last in the early period of its existence.—*Board of Trade Journal*.

CONFERENCE OF HYDROCHLORIC ACID MANUFACTURERS.

The hydrochloric acid manufacturers of Widnes, Runcorn and Birmingham have been holding a series of weekly meetings in Liverpool lately, with the object of maintaining the present high price for next year's contracts. They also considered a proposal to "pool" the whole production of the associated works, but the anticipation that other firms who have not been in the association will be sellers of acid next year has prevented its adoption. The last meeting, on October 30, authorised the members to sell at their own price, when, where, and as they liked, in the meantime. Some contracts were immediately made at 8d. per carboy, then at 7d., for considerable quantities, and more was offered at this price from Widnes than could be sold. Now 6d. per carboy is spoken of as the price for next year, though the combination quotation remains 10d. This price has been too high in comparison to the price of bleach, and it has undoubtedly reduced the consumption of hydrochloric acid. Vitriol has been far cheaper for a variety of purposes, and has been largely used in preference. By increasing the consumption of hydrochloric acid by selling it at a reasonable price, there will be the less necessity to make much more bleach next year than has been made this year. The price of bleach could be maintained by a moderate increase in the make, but it will not yet bear an increase equal to the nominal capacity of the works.—*Chemist and Druggist*.

THE BLEACH ASSOCIATION.

A meeting of members of the chemical trade was held at Liverpool on November 14, to consider the question of renewing the combination of bleaching powder manufacturers which is due to expire at the end of this year. The combination has existed for seven years, and its immediate financial results have been exceedingly beneficial to the makers, as the price of bleach, which was 4l. per ton before the combination, has been maintained by it at 6l. to 8l. per ton, the Leblanc process, by which the combined manufacturers work, being thus artificially kept up, and the output regulated to the requirements of the markets. At the Liverpool meeting it was, however, unanimously agreed not to renew the combination, as no common mode of action could be found, the proposal to continue on the basis of the limitation of the decomposition of salt by 25 per cent. proving unacceptable to the majority. From the beginning of next year there will thus be free competition in this important article, and some of the larger manufacturers

regard this prospect with much satisfaction. Coal, salt, and wages, however, are so much dearer now than seven years ago, that it is questionable whether, even without the combination, the previous low rates will return. The acid association follows the dissolution of the bleach combination.—*Ibid.*

THE AUSTRIAN SUGAR TRADE.

About 20 large beetroot sugar factories are being built in Austria-Hungary, the greater number in Hungary, where, indeed, some of them are already working. The export of sugar being at present very slack, the consequent over-production has resulted in the lowest price since 1886—14 florins 25 kreuzers for 100 kilos. of raw sugar. The present rate of production will be doubled if all the new factories in Hungary enter into competition, and the Austrian sugar industry, as apart from that of Hungary, will suffer accordingly, the Hungarian law regulating domestic taxation and the export bounties being far more favourable.

To cope with this prospect the Austrian State railways have just reduced the rates for the carriage of sugar to the frontier, and pressure is being exercised upon the southern lines to lower the rates to Trieste. Judging by this, we may expect a period of very cheap sugar, over-production being equally great in all the bounty-giving countries.—*Standard.*

ITALIAN TRADE.

It would be impossible to maintain that the financial and economic conditions of Italy can be painted altogether in rose colour; but it is instructive to note, as a set-off against some exaggerations on the other side, that here and there little awakenings of commercial activity may be observed, and that considerable productive power, hitherto dormant, is endeavouring to erect itself on a purely national basis.

As this increased activity certainly dates from the breaking off of the commercial treaty with France, it must be supposed that, together with much evil, that change brought also with it some good.

Several home industries in Italy have taken a development within the last few months which could scarcely have been the case had the general economic conditions been so bad and so unstable as they have frequently been described. Numerous and important factories have arisen, especially for the manufacture of machinery, textile fabrics, and metals. A report is being prepared, by order of the Minister of Agriculture and Commerce, tabulating the increase in this direction since 1887. This report is at present very incomplete, and notes from the various Chambers of Commerce are still wanting, but the following figures give the result of the official inquiry thus far.

Three new silk factories have arisen in the province of Udine, and one in Varese. In the latter district an important establishment for weaving silken fabrics has been erected, and two others have been enlarged. Four cotton mills have been built at Udine, Carrara, Lucrea, and Varese, and one greatly enlarged. Large establishments for the production of glass-ware, paper, dressed leather, woollen goods, soap, furniture of various descriptions, dairy produce, and alimentary produce of all kinds have in the period above indicated sprung up at Chiaravalle, Mucera, Ventimiglia, Udine, Varese, Rimini, and a long list of other places which cannot be given here; and in the province of Udine alone they included one for the manufacture of metric instruments, two for supplying plant for illumination by electricity, one for aerated waters, two for the fabrication of spirits and liqueurs, and two for carriage building.—*Ibid.*

THE CAUSE OF SPONTANEOUS COMBUSTION IN HAY.

The celebrated Breslau botanist, Professor Cohn, recently proved, by a series of exhaustive experiments, that the heating of masses of damp hay to a temperature resulting in spontaneous combustion is caused by fungus. He first examined the thermogenous action of the *Aspergillus fumigatus*, a plant having an evil reputation for causing illness, and which occasions the heating of sprouting barley.

Through the breathing of the small germ—that is to say, through the combustion of the starch and other carbohydrates, which are changed by diastatic fermentation into maltose and dextrin—an increase of temperature to about 40° C. follows, when the germs become stiff and heated, a condition in which they soon die. A heating of the germs to over 60° C. takes place only when the fermentation activity of the *Aspergillus fumigatus* sets in, and this exhibits its highest development and action in a temperature above blood heat, in which state it rapidly consumes the carbohydrates. Of all the actions of the fungus, and these are of an extremely manifold character, this action of the *Aspergillus fumigatus* is probably one of the most singular.—*Ibid.*

A CURIOUS BORAX MINE.

The *Oil, Paint, and Drug Reporter* writes as follows about a curious borax mine in the Calico district of California:—"Usually borax is obtained all over the world by collecting the accumulations of the baborate of soda in the beds of dry lakes, where the borax has been left as a residuary deposit, the same as salt and gypsum. The mine referred to is a vein found enclosed in sandstone and shale, and the borax is mined the same as quartz or any other mineral. Beautiful crystalline specimens of snowy whiteness are frequently found. The mine is a geological curiosity. The origin of the borax mine is simple enough. In past ages the now nearly vertical vein was a bed of borax in the bottom of a dry lake, where the deposit had accumulated by the evaporation of the waters of the lake, which contained the mineral in solution. Subsequently the waters spread over the land and lake, and mud and sand were carried down into the lake, and the borax was covered. This process continued until hundreds of feet of sedimentary deposit had accumulated. In the course of time these hardened and became rocks. When the main range of the Calico mountains was uplifted the borax deposit was also tilted with its enclosing rocks, and it now has every appearance of a vein. It follows perfectly, however, the line of sedimentation of the adjacent rock."—*Chemist and Druggist.*

CHEMICAL PRIZES IN FRANCE.

The French Society for the Encouragement of National Industry annually offer a large number of prizes for discoveries and researches connected with the industries, and for excellence in art work. Among the prizes which it has been decided to award for chemical subjects during the coming year are the following:—2,000 francs for the industrial preparation and application of ozone, 1,000 francs for the best process of utilisation of residual products, 1,000 francs for the most useful new application of a simple non-metallie body, 1,000 francs for the discovery of a new alloy practically useful in the arts, 1,000 francs for the discovery of the synthetic manufacture of organic bodies such as quinine, cane sugar, &c., 2,000 francs for the discovery of practically useful new tannin, 2,000 francs for a body which will replace the use of sulphuric acid in dyeing, especially in silk dyeing, two prizes of 1,000 francs and 2,000 francs respectively for the industrial manufacture, in France, of anhydrous and fuming sulphuric acid, one of 2,000 francs for improvements in the manufacture of chlorine, 3,000 francs for the manufacture of glass vessels, for use in chemical operations, 2,000 francs for the manufacturer of sulphuric acid who shall be the first to bring into commerce sulphuric acid manufactured from pyrites which shall be perfectly free from arsenic, and 4,000 francs for the most practically useful paper on chemistry or metallurgy. There are also several special prizes, one of which, of 800 francs, will be awarded every year to the workman who has been for the longest period in the employ of a single firm. The fund for this prize was contributed, at the initiative of M. Fourcade, by the exhibitors in Class 47 of the Universal Exhibition of 1878.—*Ibid.*

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

	Month ended 31st October	
	1888.	1889.
	£	£
Metals.....	2,016,123	1,735,623
Chemicals, dyestuffs, and tanning materials	490,799	560,897
Oils.....	646,769	753,132
Raw materials for non-textile industries.....	1,157,309	1,735,798

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY. APPLICATIONS.

- 16,249. J. B. A. Simonnet and S. W. Cragg. *See Class X.*
 16,283. T. A. Bullough. *See Class XVIII.—B.*
 16,289. C. Pontifex. *See Class XVII.*
 16,295. E. Gregory. Apparatus for controlling the cold air supply to heating stoves for blast furnaces and other like purposes. October 16.
 16,298. H. F. Rushton. Apparatus for draining or drawing off surface liquid from settling or depositing tanks. October 16.
 16,452. F. Hoeking. Apparatus for heating, evaporating, cooling, and condensing. October 18.
 16,478. A. de Kunwald. Improvements in and relating to distillatory apparatus. October 18.
 16,520. J. Price. Apparatus for distilling and concentrating solutions. October 19.
 16,583. A. Collingridge. Condensing apparatus. Complete Specification. October 21.
 16,588. J. Orme. Means for preventing corrosion in apparatus used for chemical or like purposes. October 21.
 16,763. J. Popper. Air condensers and cooling apparatus. October 23.
 16,863. A. H. Hobson. Apparatus for use in making extracts from and otherwise treating soluble or partially-soluble substances by means of steam pressure and heat. October 25.
 16,997. A. L    , C. A. Reman  , and A. T. Job. Air and vacuum pumps. October 28.
 17,018. W. K. Bruce. Vacuum pans. October 28.
 17,050. H. Barlow-Massieks and W. Crooke. An improved gas valve, particularly applicable for hot blast stoves or furnaces. October 29.
 17,084. V. W. Blanchard. Furnace and apparatus for generating heat. Complete Specification. October 29.
 17,184. T. O. Easton and A. Watt. *See Class XVI.*
 17,219. G. G. B. Cresswell. Evaporating and distilling apparatus. October 30.
 17,432. L. Fromm. Improvements in thermometers. Complete Specification. November 2.
 17,505. J. Martinez-Ancira. An improved centrifugal pump. Complete Specification. November 4.
 17,637. T. Duggan. Making a non-conducting heat composition for application to steam boilers, steam pipes, cylinders, char kilns in sugar refineries, &c. November 6.
 17,686. R. Davidson and E. Emanuel. Apparatus for supplying a continuous and unvarying quantity of air to blast furnaces, blow pipes, &c. Complete Specification. November 6.
 17,775. E. W. Killiek. Improvements in and relating to the drying chambers of kilns. November 7.
 17,814. H. Hanneville. An improved serpentine coil for evaporation, suitable for the concentration of sulphuric acid. November 8.
 17,853. W. W. Beaumont and J. Kirkaldy. Improvements in condensers, distillers, water heaters, and coolers. November 8.
 17,938. J. G. Chamberlain and G. E. Davis. Apparatus for the evaporation of liquids. November 11.
 18,108. J. Ruscoe. Apparatus for charging and drawing retorts mechanically. November 13.

18,153. J. Foster. Vacuum evaporating and distilling apparatus. November 13.

18,169. R. Fradera. Apparatus for vaporising water and other liquids. November 14.

18,324. W. W. Bengough. Apparatus for heating, evaporating, and condensing, applicable as a feed-water heater, distiller, or condenser. November 16.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

15,460. R. Cunliffe. Apparatus for calcining, drying, roasting, or carbonising substances, and extracting gases, spirits, acids, &c. therefrom. October 23.

16,139. E. Fahrig and H. E. Billing. Apparatus for production of ozone. November 6.

18,153. J. Foxhall. Controlling the pressure of gas, fluids, and liquids. November 13.

18,954. G. C. Dymond.—From The A  rated Fuel Co. Furnaces for utilising hydrocarbons as fuel, and operating devices therefor. October 30.

1889.

34. T. Slater. Apparatus for evaporating liquids. November 6.

13,549. H. Bower. Process for facilitating chemical reactions. October 23.

16,037. H. H. Lake.—From C. A. Catlin, C. S. Sweetland, and R. Cox. Charging liquids with gas. November 20.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

16,138. E. Tatham. Improved gas or gaseous mixtures for use in the production of light, heat, and power. Complete Specification. October 14.

16,142. E. Tatbam. Improvements in coal-gas and like gases, and in the manufacture thereof. Complete Specification. October 14.

16,223. W. C. Sellar. Improvements in the method of using coal and other substances for generating heat. October 15.

16,441. T. H. Gray and S. S. Bromhead. Improvements in the preparation of coal-gas for combustion. October 18.

16,486. A. Coze. Improvements in gas retorts and in apparatus connected therewith. October 18.

16,488. J. R. Wigham. Improvements in lighthouse illumination. October 18.

16,489. F. Morris and L. van Vestrant. Improvements in apparatus for charging inclined gas retorts. October 18.

16,646. D. H. Knapp. Improvements in the manufacture of gas. Complete Specification. October 22.

16,795. D. Dixon. Improvements in the methods of generating gas for heating and other purposes, and in the apparatus used therefor. October 24.

16,889. G. Bower. Means or apparatus for carburetting air or gas. October 25.

16,977. J. A. Yeadon and R. Middleton. An improved method of utilising small coke or breeze. October 28.

17,001. F. H. Crittall. Improvements in screw caps or covers for closing the openings in hydrocarbon chambers of gas-light apparatus and other uses. October 28.

17,134. J. Jones. Improvements in the method of and apparatus for burning fuel, debris, and water, and for consuming smoke in furnaces and fireplaces, and utilising the products thereof. October 29.

17,140. A. A. Fritz. Apparatus for producing an inflammable gas by carburation of air. October 29.

17,232. N. M. Henderson. Improvements in apparatus for distilling mineral oils. October 31.

17,467. E. Lund. Improvements in nightlights and similar articles, and in the holders used in burning the same. November 4.

17,480. J. H. Wood. A new or improved artificial fuel. November 4.

17,535. F. B. Dortmund. Improvements in manufacturing coke. November 5.

17,673. The Coltness Iron Co., Lim., and W. Young. See Class X.

17,697. D. Irving. Improvements in hydraulic gas mains, and in valves connected therewith. Complete Specification. November 6.

17,700. J. W. Thomas, F. S. Harbridge, and D. Thomas. An improved system of ventilation, smoke prevention, and combustion of fuel. November 6.

17,778. H. H. Lake.—From G. W. Wilcox, United States. Improved apparatus for preventing the formation of smoke and for effecting economy in the consumption of fuel. November 7.

17,810. J. H. R. Dinsmore. Improvements in and connected with the manufacture of illuminating gas. November 8.

17,817. E. de Pass.—From E. Demagnin and L. Bourdier, France. An improved firelighter, serving also as fuel. November 8.

17,945. J. Morley. A compound for making into fire-lighters. November 11.

17,954. T. D. Rock. Improvements in coking and in coke ovens and plants connected therewith. November 11.

18,063. A. L. Blackman. Improvements in the manufacture of peat fuel. November 12.

18,064. A. L. Blackman. Improvements in or relating to the treatment of peat. November 12.

18,162. F. Pritchard. Enriching and increasing the volume of gas obtained from coal, and the utilisation of waste heat from retort settings. November 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,935. D. Latchinoff. Production of oxygen and hydrogen in large quantities for ballooning, by the electrolysis of water. November 13.

16,179. I. Carr. Manufacture of illuminating gas. October 13.

16,217. J. Jefferay. A new firelighter. November 13.

16,970. B. H. Thwaite. Producing combustible gases, and apparatus therefor. November 13.

17,869. F. B. Hill. Apparatus for utilising liquid hydrocarbon for lighting and heating. November 13.

18,451. E. Brook and J. J. Brook. Regenerative kilns. November 20.

18,573. E. Solvay. Purification of gases. October 23.

18,678. F. R. Jones. Preventing the emission of smoke from chimneys. October 23.

18,918. J. Nimmo and J. Scotland. Manufacture of coke, and ovens, &c., therefor. November 6.

18,954. G. C. Dymond.—From The Aërated Fuel Co. See Class I.

1889.

703. H. S. Maxim. Apparatus for carburetting gas. October 30.

1271. H. Simon. Coke ovens. November 6.

2508. H. S. Maxim. Apparatus for carburetting gas. October 30.

7252. J. von Langer and L. Cooper. Generation of water-gas, Siemens-gas, and producer-gas, and apparatus therefor. November 20.

10,700. J. W. Rock, C. G. Moore, J. H. Wood, and J. B. Nicholson. Gas-making apparatus. October 23.

12,584. R. R. Main, A. P. Main, and H. Darwin. Gas fires. October 23.

14,031. J. Loves. Apparatus for carburetting gas or air. November 20.

14,291. S. Pitt.—From C. B. Harris. Apparatus for the manufacture of gas. October 23.

14,644. W. P. Thompson.—From F. P. Dewey. Separating and collecting the solid materials from fume, smoke, &c. November 6.

14,686. H. Howell and L. Smith. Apparatus for enriching or generating illuminating gas from volatile liquid hydrocarbons. October 23.

14,881. A. Kitt. Gas-making apparatus. October 30.

14,922. A. Kitson. Apparatus for manufacturing heating gas. November 6.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATION.

16,554. O. Imray.—From J. Dehust, Germany. Process for the purification of crude naphthalin. October 19.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

16,261. The Clayton Aniline Company, Limited, and P. Brunner. A method of preparation of new azo dyestuffs. October 16.

16,382. S. R. Brinkworth. Improvement in dyes for leather goods. October 17.

16,448. J. Dawson. Manufacture of a grey basic colouring matter soluble in water. October 18.

16,698. S. Pitt.—From L. Cassella and Co., Germany. Production of new colouring matter. Complete Specification. October 22.

16,699. S. Pitt.—From L. Cassella and Co. The preparation of amidonaphtholsulphonic acid and of colouring matters therefrom. October 22.

17,204. O. Imray.—From The Farbwerke Griesheim-on-Main, W. Noetzel and Co., Germany. Manufacture of indulin-like colouring matters. October 30.

17,223. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. An improved manufacture of colouring matter. October 30.

17,491. O. Imray.—From The Farbwerke Vormals Meister, Lucius, und Brüning, Germany. Improved manufacture of diazonaphtholmonosulphonic acids, and of diazonaphtholdisulphonic acids. November 4.

17,957. O. Imray.—From The Actien Gesellschaft für Anilin Fabrikation, Berlin. Process for the preparation of orange-yellow colouring matters. November 11.

17,964. J. O. O'Brien.—From The Fabriques de Produits Chimiques de Tann et de Mulhouse, Germany. Improvements in the production of azo-colours upon cotton or other fabrics of a vegetable nature by printing or dyeing. November 11.

17,971. H. H. Lake.—From A. Leonhardt and Co., Germany. Improvements relating to colouring matters. November 11.

18,217. C. Romen. A process for rendering dry alizarine fit for colouring and printing purposes. November 14.

18,354. B. Wilcox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture and production of direct-dyeing yellow colouring matters. November 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

16,333. B. Wilcox.—From The Farbenfabriken vorm. F. Bayer and Co. Production of a new sulphone or diethylsulphone-methyl-ethyl-methane. October 23.

17,333. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. A new manufacture of dyestuffs. November 6.

1889.

2941. T. R. Shillito.—From J. R. Geigy. A new violet dye or colouring matter. November 6.

12,767. H. H. Leigh.—From R. G. Williams. Manufacture of mixed azo-colours. November 6.

15,360. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran. Manufacture of new derivatives of tannin and catechin, and of colouring matters therefrom. November 6.

15,558. F. Rhodes. Dye-extracting apparatus. November 13.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

16,258. J. Schofield. Improvements in the production of cotton yarn, and in machinery therefor. October 16.

16,708. C. Baswitz. Improvements in the treatment of textiles by means of copper and ammonia for the purpose of making them waterproof and unflammable. Complete Specification. October 22.

17,137. E. Johnson.—From T. Burrows, France. Improved means and apparatus for ungumming and otherwise treating flax and other like fibres, also leaves and plants. October 29.

17,449. P. J. Evans, A. Evans, and E. E. Evans. Preparing for spinning a woollen yarn, so that one, two, or more colours can be spun or doubled by one process. November 4.

18,180. I. Smith and J. Smith. Improvements in the method of and apparatus for treating or scouring and washing wool and other fibrous substances. November 14.

COMPLETE SPECIFICATION ACCEPTED.

1888.

17,429. G. L. P. Eyre and T. J. Hopkins. Process of treating and scouring wool and other materials containing fatty matters, and apparatus therefor. October 23.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

16,156. T. Holliday. Improvements in producing azo-colours on or in cotton or other textile fibre or fabric. October 11.

16,157. T. Holliday. Improvements in preparing cotton or other textile fibre for the production thereon of certain azo-colours. October 14.

16,368. A. Greg. A new or improved method of bleaching wood bobbins, reels, and other articles made from wood. October 17.

16,822. W. Junge. Improvements in apparatus chiefly designed for washing, bleaching, dyeing, impregnating, or drying fabrics and other materials. October 24.

16,925. J. H. Gartside. Improvements in and apparatus for bleaching fibres, yarns, and woven or other fabrics. October 26.

17,321. F. M. von Kalkreith Browne. See Class VIII.

17,964. J. O. O'Brien.—From The Fabriques de Produits Chimiques de Thann et de Mulhouse, Germany. See Class IV.

18,073. B. Willecox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. Dyeing and printing animal and vegetable fibres with dinaphthyl-dichinhydrone, or with beta-naphtho-chinone, or tetra-oxydinaphthyl. November 12.

18,115. A. Graemiger. Improvements in machines for dyeing, bleaching, or otherwise treating fibres in a raw, spun, woven, or intermediate state of manufacture. November 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,010. J. Inray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Dyeing cotton or other vegetable fibres with blended colours. October 30.

1889.

197. J. Inray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Process for dyeing with yellow, orange, and red azoic colouring matters. October 30.

350. W. Mather.—From V. G. Bloede. Process for tinting fabrics with fast colours. November 6.

376. W. L. Wise.—From M. von Gallois. Manufacture of new chrome mordanting substances, and the application thereof for dyeing and printing. November 13.

2525. H. Erdmann. Cold process of dyeing hair and feathers by means of paraphenylenediamine or similar bases. November 20.

2743. F. A. Blair. Vats for dyeing, washing, bleaching, and mordanting fibrous materials. October 23.

15,881. J. C. Mewburn.—From La Société Grandsire et fils. Apparatus for dyeing skins. November 13.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

16,213. W. Shapleigh. Improvements in the method of producing chloride of lead. Complete Specification. October 15.

16,351. L. Q. Brin, A. Brin, and F. H. Varley. An improved process of and apparatus for extracting phosphates from associated earthy substances. October 17.

16,609. W. Wolters. A new or improved process for the recovery or regeneration of nitric acid employed in the manufacture of chlorine. October 21.

16,630. R. H. Steedman, A. Campbell, and W. Boyd. Improvements in obtaining chlorine and alkali and in reconverting and utilising by-products of the processes. October 22.

16,711. E. Augé. Improvements in the manufacture of soda alum. October 22.

16,928. W. Borrows and N. J. Borrows. Improvements in the treatment of black-ash waste, applicable for use with Chance's sulphur recovery process, and in apparatus therefor. October 26.

17,054. J. Pointon. Improvements in and relating to the manufacture of sodium carbonate and apparatus therefor, applicable also to the manufacture of potassium carbonate. October 29.

17,055. J. Pointon. Improvements in and relating to the manufacture of alkaline manganates, and apparatus therefor. October 29.

17,056. J. Pointon. Improvements in and relating to apparatus for the manufacture of alkaline silicates and aluminates, applicable also to other purposes. October 29.

17,074. T. Turner. Improvements in the treatment of waste pickle from galvanising works, and other such like acid liquors, and in the apparatus employed therefor. October 29.

17,217. F. M. Lyte and J. G. Tatters. Improvements in the recovery of chlorine from the residual liquors of the ammonia-soda process, from solutions of calcium chloride, from certain impure solutions of magnesic chloride, and from some other industrial residues. October 30.

17,218. F. M. Lyte and J. G. Tatters. Improvements in the production of hydrochloric acid from certain industrial residues, together with the recovery of sulphur and oxide of magnesium. October 30.

17,272. P. de Wilde and A. Reyehler. Processes for the production of chlorine, and for obtaining concentrated gaseous hydrochloric acid for that purpose. October 31.

17,348. J. E. J. Johnson. Improvements in the manufacture of acetic acid and calcium sulphite. Complete Specification. November 1.

17,395. W. Garroway. Improvements in obtaining caustic soda or caustic potash by means of boracic acid. November 2.

17,730. W. Darling and J. Anderson. Abstracting sulphur from sulphurous coal or ores or other minerals. November 7.

17,888. F. M. Spence and D. D. Spence. Improvements in the manufacture of alum. November 9.

17,916. C. F. Claus. Improvements in the manufacture of soda. November 9.

18,356. E. Bowen. Improvements in or connected with the manufacture or production of ammoniacal salts. November 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,541. M. Flaschendräger and H. Flaschendräger. Flat or prismatic evaporating pans for the treatment of salt. October 23.

17,807. J. V. Hewson. Treatment of salt, and means therefor. October 23.

17,930. M. H. Simpson. Preparation and treatment of bromine for the extraction of gold from ore, or for other purposes. November 6.

18,056. A. Campbell and W. Boyd. Obtaining chlorine. October 23.

18,921. R. H. Steedman and A. J. Kirkpatrick. Reconvertng and utilising by-products formed in processes for obtaining chlorine. November 13.

19,023. E. W. Parnell and J. Simpson. Treating alkaline sulphides in solution, or an aqueous mixture of same with carbonic acid gas, for production of sulphuretted hydrogen, and apparatus therefor. November 20.

1889.

881. R. H. Steedman and A. J. Kirkpatrick. Obtaining chlorine, and reconvertng and utilising the by-products. November 20.

1007. O. E. Pohl. Manufacture of salt and apparatus therefor. November 20.

7901. G. Veitch. Concentration of sulphuric acid, and apparatus therefor. October 23.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

16,264. W. West. Improvements in the mode and means employed for the manufacture of flower or plant pots or other articles from clay or other semi-plastic material. October 16.

16,285. R. B. Baugh. Improvements in or connected with the brushing-out process in the manufacture of lettered or decorated enamelled metal or glass plates, or other similar surfaces. October 16.

16,326. E. Smith. Improvements in apparatus for making earthenware socket pipes. October 16.

16,449. R. B. Baugh. Improvements in or connected with the brushing-out process in the manufacture of lettered or decorated enamelled metal or glass plates, or other similar surfaces. October 18.

16,475. W. B. Fitch. Improvements in the manufacture of metal-coated glass and porcelain bottles, jars, jugs, stoppers, and other like articles. October 18.

16,536. H. Hall. Improvements in tiles for lining walls and other surfaces. Complete Specification. October 19.

16,683. E. Leak and H. Aynsley. Improved apparatus for supporting pottery ware while being fired. Complete Specification. October 22.

16,696. F. E. Rostaing, L. A. Garchey, and N. E. Geille. An improved manufacture of vitreous material suitable for artificial marble, stained glass, and analogous objects. October 22.

16,742. E. Leak and H. Aynsley. Improved means to be used in supporting pottery ware while being baked or otherwise fired. Complete Specification. October 23.

16,744. J. Hall. An improvement in the manufacture of fireclay goods and of refractory material for lining Bessemer converters or other like purposes, and the preparation of a substance for use in such manufacture. October 23.

16,843. A. Drummond. Improvements in apparatus for rolling out glass sheets with designs or patterns upon the surface. October 25.

17,064. G. Scott. A new or improved method of manufacturing glass slates, and in the apparatus employed therefor. October 29.

17,105. J. B. Curtis and J. W. Mackintosh. Improvements relating to the manufacture of hollow-ware from glass and similar material. Complete Specification. October 29.

17,320. G. A. Gritton. An improved method for blowing ink wells in moulds. November 1.

17,321. F. M. von Kalkreuth Browne. Producing printed designs in any number of colours by one operation of machinery, especially for pottery decoration. November 1.

17,142. J. Hamblet and A. Plant. Improvements in the manufacture of flooring tiles and other similar tiles. November 2.

17,446. J. P. Guy. A machine for pressing and making solid fireclay and other solid earthenware articles. November 2.

17,468. D. Rylands. Improved means of manufacturing hollow glass ware and glass tubes by machinery. November 4.

17,565. J. G. Sowerby. Improvement in the manufacture of antique and other descriptions of sheet glass, and improved apparatus in connexion therewith. November 5.

17,933. D. Rylands and J. W. Horner. Improved means or apparatus for withdrawing molten glass or molten metals from furnaces, and controlling the outflow thereof. November 11.

18,070. W. B. Fitch. Improvements in the manufacture of glass bottles and similar articles. November 12.

18,094. J. Powell and W. Powell. Improvements in earthenware pots for horticultural or other purposes, and appliances for making the same. November 13.

18,152. B. J. Brearley. Improvements in the construction and arrangement of plant and machinery for casting, rolling, and annealing plate glass. November 13.

18,242. J. J. Downes. Enamelled metal tile hearth and sheets of enamelled metal tiles for wall decorations and ceilings. November 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7919. R. T. Grocott. Apparatus for making certain articles of pottery ware. November 13.

17,965. W. Boulton. Apparatus for blending potters' clay, &c. October 23.

18,238. W. Ambler. Manufacture of sheet glass and cylindrical glass articles. October 23.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

16,327. G. B. Jerram. Improvements in paving for roadways, pathways, and floors. October 16.

16,579. W. Bradford. A flooring material. October 24.

16,941. H. D. Blake. Improvements in block paving. October 26.

17,211. W. S. Akerman. Improvements relating to kilns or ovens for burning cement, lime, bricks, and other materials, and to the utilisation of the waste heat therefrom. October 30.

17,280. L. Blumer and J. Tait. Improvements in lime kilns. October 31.

17,623. R. E. B. Crompton and B. H. Jenkinson. Improvements in resistant coverings for battery room floors or surfaces, laboratory floors, and like uses. November 5.

17,640. W. P. Thompson.—From C. Kohn, Austria. Improvements in the manufacture of artificial stone or of articles formed of the same. Complete Specification. November 6.

17,758. H. A. Bassett. Improvements in the manufacture of building material for architectural and other purposes, and of a composition for use in connexion therewith. November 7.

17,908. S. J. Warr. Improvements in ornamental bricks or mouldings, and in dies to be used in the manufacture of the said bricks or mouldings. November 9.

17,961. J. C. Fell.—From G. Phillips, United States. Improvements in the coating or covering of exposed wooden structures or timbers. Complete Specification. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,041. G. J. Randall and F. Carter. Hardening the surfaces of soft oolites limestone, for the purpose of enamelling same and producing imitation marble, &c. October 23.

17,503. J. Cadbury. Machinery for polishing or surfacing glass. October 30.

18,491. W. Joy. Apparatus for use in the preparation of slurry, and in mixing slurry with fuel. October 23.

1889.

11,922. G. F. Redfern.—From J. G. Maardt. Composition for covering walls, &c. November 6.

12,623. T. Shaw. Utilising the waste product from sewage works for the manufacture of building materials. November 6.

14,281. S. Jørgensen. Heating cements and hydraulic lime. November 13.

14,515. A. J. Paris. Cloth-covered plaster blocks for ceilings, walls, &c. October 23.

15,669. J. Ersley. Manufacture of artificial asphalt. November 13.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

16,249. J. B. A. Simonnet and S. W. Cragg. Improvements in apparatus for filtering, more especially adapted for use with apparatus used for the extraction of gold, silver, and other metals from their ores. October 15.

16,250. J. B. A. Simonnet and S. W. Cragg. Improvements in means or apparatus for the extraction of gold, silver, and other metals from their ores. October 15.

16,318. H. Marbeau. Improvements in the manufacture of alloys of nickel with other metals. October 16.

16,338. F. E. Ross. Improvements in furnaces such as cupolas and blast furnaces. October 16.

16,394. J. H. Darby. Improvements in the manufacture of iron from iron sand or fragmentary or other soft iron ores. October 17.

16,396. W. P. Thompson.—From J. B. Brewster, United States. Improvements in or relating to amalgamators for extracting precious metals from the various impurities combined with them in ores or the like. October 17.

16,447. C. A. Burghardt. Improvements in the manufacture of tin plates. October 18.

16,474. R. F. Ludlow. An improved method of decarbonising iron. Complete Specification. October 18.

16,649. G. G. Mullins. An improvement in the art of treating copper and its alloys. Complete Specification. October 22.

16,760. A. Briu. Improvements in the production of aluminium and aluminium alloys. October 23.

16,776. J. B. Alzugaray. A new metallurgical dry process by means of Baxere's universal furnace. October 24.

16,794. D. Dixon. Improvements in the manufacture of aluminium and other metals. October 24.

16,868. E. A. Cowper. A method of recovering float gold. October 25.

16,871. J. J. C. Fernau and E. H. Hartmont. Improvements in appliances for calcining and smelting copper. October 25.

16,960. J. M. Bennett. Improved means for smelting metals and the recovery of volatile and other metallic products escaping therefrom. October 26.

16,979. T. Doughty. Annealing case for steel ingots. October 28.

17,060. T. Packer. Improvements in electrical furnaces and their manipulation. October 29.

17,063. F. D. Taylor. Improvements in or connected with moulding or casting, and in moulds therefor. Complete Specification. October 29.

17,178. F. Wicks. Improvements in the process of alloying metals by vapours, and particularly by sublimated aluminium. October 30.

17,269. W. D. Bohm. Improvements in hydrometallurgical apparatus. October 31.

17,319. G. W. Hart. A process and apparatus for deoxidising or reducing metallic oxides. November 1.

17,393. J. Evans. Improvements in cupolas. November 2.

17,492. E. H. Cook and W. T. Gibbs. Improvements in the manufacture of aluminium. November 4.

17,512. S. W. Cragg. Improvements in and connected with apparatus or means for separating gold, silver, and other metals from their ores, or materials containing them, or for analogous operations. November 4.

17,627. H. H. Lake.—From S. H. Emmens, United States. Improvements in the production of ductile iron from cast iron.

17,673. The Coltness Iron Co., Limited, and W. Young. Improvements in treating gases from blast furnaces, gas producers, and coke ovens, and in apparatus therefor. November 6.

17,699. C. Davy. Improved means for suspending and manipulating ingots or forgings whilst being heated and operated upon. November 6.

17,701. J. C. Orr. Improvements in and relating to the treatment of furnace slag, and the recovery of by-products therefrom. November 6.

17,878. J. Meese. Improved means and process for treating iron and other metals, and the production of a fireproof coating thereon preparatory to ornamenting with fusible colours. November 9.

17,890. A. Evard. The application of baths of molten metals to the tempering, annealing, or treating of castings or forgings of copper, nickel, cobalt, and aluminium, and of alloys of these metals with each other, or with manganese, cast or wrought iron, or steel. November 9.

17,911. M. J. Berg. Improvements in the manufacture of aluminium. November 9.

17,933. D. Rylands and J. W. Horner. See Class VIII.

18,048. S. Pearson and J. H. Pratt. Improvements in the manufacture of alloys of iron and aluminium and alloys of steel and aluminium. November 12.

18,061. H. Y. Castner. Improvements in the manufacture of sodium and potassium. November 12.

18,062. H. V. Castner. Improved process of purifying the anhydrous double chloride compounds of aluminium. November 12.

18,170. J. Pointon. Improved wet copper extraction process, applicable also to the production of sulphate of copper and iron. November 11.

18,297. T. Haeghe and The Cape Copper Co., Lim. Improvements in the treatment of copper or cupreous compounds for the production of sulphate of copper and the extraction of the precious metals, and in apparatus applicable therefor. November 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

15,698. A. Levy. Dipping process for depositing metals upon iron and steel. November 6.

16,567. H. Schneider. Manufacture of iron and steel alloyed with nickel. November 13.

16,568. H. Schneider. Manufacture of iron and steel alloyed with copper. November 13.

16,796. J. H. Pollok. Wet method of extracting gold from crushed ores, &c. November 20.

17,269. G. Prout and D. Murray. Coating iron or steel plates with copper or other comparatively non-oxidisable metals. October 30.

17,420. A. Wylie. Manufacturing metal pipes and rods, and covering same (or telegraph and telephone cables and wires) with lead or metallic compounds for electric purposes. October 30.

17,476. W. Charnocks. Coating certain metals with other metals or alloys. November 13.

18,178. D. Davy. Apparatus for traversing and turning ingots and blooms. October 23.

18,218. G. Prout and D. Murray. Coating iron or steel with copper and other comparatively non-oxidisable metals. October 30.

18,632. T. Summers. Cleaning tin, terne, or other metal plates, and apparatus therefor. November 6.

1889.

28. A. B. Cunningham.—From H. Havemann. Extraction of gold, silver, and lead from substances containing same, and apparatus therefor. November 13.

187. P. M. Parsons. Production of metallic alloys. November 20.

359. C. Netto. Extraction of aluminium from cryolite &c. November 20.

769. R. S. Casson. Casting metals. November 20.

841. J. B. Hannay. Extracting precious metals from ores. November 20.

890. R. Stanfield and T. Clarkson. Separating metals and heavy minerals from ores. November 20.

1099. J. Richardson. Manufacture of iron and steel. November 20.

7013. L. Petit-Devaucelle. Manufacture of aluminium and alloys thereof. November 13.

11,021. P. H. Adams, jun., and O. T. X. Adams. Apparatus for smelting ores. November 6.

11,083. P. H. Adams, jun., and O. T. X. Adams. Apparatus for smelting ores. November 6.

12,322. F. L. Bartlett. Treatment of ores containing lead, zinc, and other metals. October 23.

14,235. C. Schreiber and H. Knutsen. Treatment of auriferous and argentiferous antimony ores. November 20.

14,473. M. A. Howell, jun. Manufacture of soft back steel, and apparatus therefor. November 6.

15,428. T. F. Rowland. Apparatus for welding metals. November 6.

15,824. G. Archbold. Manufacture of iron and steel. November 13.

15,887. P. P. Craven. A fluxing material for use in welding, brazing, and coating metals. November 13.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

16,130. A. E. Robinson. An improvement in conductors or poles for use in electrical furnaces. October 11.

16,210. A. Wolfshmidt and C. Brehm. Improvements in electric dry batteries. October 15.

16,231. G. Pfannkuche. Improvements in dynamo-electric generators. Complete Specification. October 15.

16,241. H. H. Carpenter. Improvements in secondary or electric storage batteries. Complete Specification. October 15.

16,375. C. B. de Montaud. Improvements in secondary batteries. October 17.

16,555. W. J. Brewer. Improvements in electric storage batteries. October 22.

16,890. E. Frankland, A. H. Hough, and D. G. Fitzgerald. Improvements in elements for secondary batteries. October 25.

17,025. A. S. Elmore. Improvements in the process for obtaining zinc by electrolysis. October 30.

17,252. F. M. A. Laurent-Cély and I. A. Timmis. Improvements in electric secondary cells. October 31.

17,793. G. J. Weir and A. Weir. Improvements in galvanic batteries. November 8.

17,831. J. V. Sherrin. Improvements in electric battery carbon, and carbon compound elements and their connexions. November 8.

17,974. H. H. Lake.—From H. Lemp, United States. Improvements in apparatus for welding by aid of electricity, which improvements are also applicable for other purposes. November 11.

18,067. A. B. Cunningham. Improvements in the manufacture of secondary batteries or accumulators. November 12.

18,350. J. H. Davies. Improvements in dynamo-electric machines. November 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,858. F. J. Brougham.—From La Société Perreux-Lloyd et fils. Electro-chemical generators. November 20.

18,968. E. L. Zalinski and H. J. Smith. See Class XXII.

18,978. T. W. Bush. An oblique meshed grid plate for storage batteries. November 6.

18,981. M. Doubleday. An inner expanded chamber grid plate for storage batteries. October 30.

18,994. G. C. Dymond.—From J. M. A. G. Léscuyer. Manufacture of metals or alloys by means of electricity. November 20.

19,058. J. Y. Johnson.—From F. Gendron. Electric batteries. November 6.

1889.

126. G. B. Lückhoff. An improvement in dynamos. November 13.

997. T. Cuttriss. Secondary batteries. November 13.

11,601. G. Macanlay-Cruikshank.—From S. H. Barrett. Connector for the elements of electric batteries. October 23.

15,383. G. E. Heyl. Manufacture of electrodes for accumulators from chromates and wolframates, and from amalgams of chrome or of wolfram with other metals. November 6.

15,446. S. C. C. Carrie. Method and apparatus for "forming" or charging plates for accumulators. November 6.

15,775. C. F. Winkler. Electro-dynamic and dynamo-electric machines. November 20.

15,821. S. C. C. Currie. Electrolytically reducing plates of metallic salts to a metal state to "form" the electrodes of secondary batteries. November 20.

16,231. G. Pfaukuche. Improvements in dynamo-electric generators. October 23.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

16,347. G. Henschell and P. W. Kitto. Improvements in the manufacture of soap tablets. October 17.

16,518. T. Anyon. Improvements in the composition of soap. October 19.

16,525. P. Smith. Improved preparation of petroleum for cleansing, washing, polishing, and similar domestic operations. October 19.

16,671. H. Duerden. Improvements in the treatment of raw lard and lard compounds. October 22.

16,805. W. P. Thompson and G. Tall. Improvements in or relating to the treating or purification of crude or semi-refined cotton-seed oil. October 24.

16,821. M. D. Penney. Improved method of or process for extracting or removing oil from oil-containing bodies, animal and vegetable. October 24.

17,163. W. Brinck. An improvement in lubricants. October 30.

17,385. T. T. Wildridge. Soap cores—or the inclusion in pieces of soap of various contrivances for the increase of economy and convenience. November 2.

17,741. W. Hepworth-Collins and W. J. Smith. An improved dry soap or washing powder. Complete Specification. November 7.

17,742. W. Hepworth-Collins and W. J. Smith. A disinfectant and detergent dry soap or washing powder, or soap extract or essence. Complete Specification. November 7.

17,870. R. Hunt. Improvements in treating crude cotton-seed oil, and oils containing resinous matter and free fatty acids, to obtain oil-soap and resinous colouring matter. November 9.

18,046. C. H. Robinson. A new method of thickening linseed oil. Complete Specification. November 12.

18,345. H. A. A. Dombain and O. Trumper. Improvements in apparatus for extracting fatty and other matter from substances by means of volatile solvents. November 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

16,845. J. Gott. Manufacture of soft soap. November 13.

18,782. R. Stone. Manufacture of soap. November 20.

1889.

1430. J. Ascough. See Class XVIII.—C.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

16,545. L. Schulhof and M. B. Vogel. Method of manufacturing glycerio-tannic acid, and by its means lakes soluble in water. October 19.

16,706. P. Broumer. Improvements in the manufacture of white lead. October 22.

17,236. G. E. Heyl. The manufacture of isolating compositions for cables. October 31.

17,264. A. Melville and P. Whitecomb. Improvements in the manufacture of solid inks and the like. October 31.

17,671. W. S. Courad and H. T. Lilley. An improved copying ink. November 6.

17,771. W. P. Thompson.—From E. W. Mus, Holland. New or improved composition applicable for protecting or preserving the bottoms of navigable vessels, pontoons, or the like, and for preventing the adherence thereon of seaweed, limoria, and other like marine vegetable or animal growth. November 7.

18,042. J. C. Martin. Improvements in pigments or paints. November 12.

18,076. H. H. Lake.—From J. B. Tibbits, United States. Improvements relating to the manufacture of white lead. November 12.

18,286. T. Pridham. An improved preservative and waterproof coating for metals, timber, masonry, concrete, or other structures or surfaces. Complete Specification. November 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,705. H. B. Condy. Manufacture of white lead. November 13.

18,716. C. Mortit. Manufacture of rosin liquor for paper makers. October 23.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

16,595. H. Bogenschild and F. Busch. Process and apparatus for glazing leather. October 21.

17,328. W. A. Leonard. Greatly facilitating the tanning of hides, &c., and forcing syrup into lemon, orange, and citron peels, &c. November 1.

17,436. H. J. Haddan.—From J. Landini. A new process for discolouring tannic acid solutions. November 2.

17,813. R. M. Presland, sen. An improved waterproofing for leather. November 8.

17,941. H. Belcher. Improvements in the treatment of skins and hides for the preparation of leather. November 11.

18,307. W. S. Smith. An improved method of utilising waste or secondary products obtained in certain processes of leather manufacture. November 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

16,545. L. D. S. Cufflin and G. Hughes. Machine for extracting the hair from skins. November 13.

17,782. P. A. Jesson. Machinery for treating hides, skins, and leather. November 6.

18,399. M. P. Halsechek. Extract for use as a ferment, and as leather food or dressing. October 23.

1889.

645. H. E. Frendenberg. Treatment of hides and skins, and apparatus therefor. October 23.

12,070. A. Weber. Kilns for burning bone-black. November 20.

12,521. J. Hauff. Process for freeing kips, skins, and hides from lime, and causing same to swell. October 30.

14,595. A. Hull. Preparing hides for tanning. October 30.

XV.—AGRICULTURE AND MANURES.

APPLICATIONS.

16,351. L. Q. Brin, A. Brin, and F. H. Varley. See Class VII.

18,148. J. T. Dinsdale and W. B. Kemshead. See Class XVIII.—B.

COMPLETE SPECIFICATION ACCEPTED.

1889.

14,633. N. B. Powder. A compound of animal substances and earths containing phosphate of iron and alumina for fertilising purposes. November 20.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

16,540. A. Wohl and A. Kollrepp. Improvements in the production of invert sugar. October 19.

17,184. T. O. Easton and A. Watt. Improvements in or appertaining to apparatus for filtering saccharine or other liquids. October 30.

COMPLETE SPECIFICATION ACCEPTED.

1889.

9021. J. Foster. Drawing off and condensing the vapour from sugar pans, and apparatus therefor. November 20.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

16,289. C. Pontifex. Improvements in refrigerators for cooling brewers' worts or other hot liquids. October 16.

16,325. C. P. Goode. Improvements in the treatment of brewers' grains for cattle food. Complete Specification. October 16.

16,556. D. Wickham. Novel construction or arrangement of condensing cylinder, used for gasating malt and other liquors. October 19.

16,906. W. B. Giles and A. Shearer. Improvements in brewing and the treatment of worts for distillers' use. October 26.

16,947. A. de Méritens. Improvements in treating and rectifying or ageing alcohol or alcoholic liquors or the like by electricity. October 26.

17,431. J. White. Improvements in the manufacture of of degerminated, flaked, boiled, and torrefied maize to be used for brewing and distilling purposes, and also as a prepared and cooked food, and in apparatus employed therein. November 2.

17,515. J. Lillie. Improvements in treating, ageing, or purifying alcoholic or other liquids, and in means or apparatus employed therein. November 4.

17,523. H. H. Lake.—From J. Barnes, United States. Improvements in yeast cakes. Complete Specification. November 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,225. A. Behr. Apparatus for malting grain. November 13.

14,965. E. A. B. Beaumont. Rendering alcoholic liquors more wholesome. October 23.

17,338. H. E. Sorel. Treatment of commercial alcohols. November 20.

18,286. H. A. Birrell. Treatment of ground malt for brewing purposes, and apparatus therefor. November 6.

18,422. C. Philippart. Improving the quality of alcohols and alcoholic liquors. October 23.

1889.

86. O. Inray.—From A. Bergh. Process and apparatus for aerating and purifying beer worts and beer. November 13.

14,642. L. Frisch. Manufacture of beer, ale, porter, and the like. October 23.

16,325. C. P. Goode. Improvements in the treatment of brewers' grains for cattle food. October 23.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

16,325. C. P. Goode. See Class XVII.

17,380. R. Denby. Improvements in the preparation of rennet powder for use in cheese making. Complete Specification. November 2.

17,434. J. White. See Class XVII.

18,195. F. T. Robinson.—From R. Robinson, New Zealand. Improvements in, or process for, the preservation of articles of food or other animal or vegetable matters. November 14.

B.—Sanitary Chemistry.

16,283. T. A. Bullough. Improvements in or appertaining to filters for filtering sludge and other semi-liquid matter. October 16.

16,298. H. F. Rushton. See Class I.

16,388. G. W. Brenner. Improvements in lamps for destroying sewage gas and noxious vapours. October 17.

16,867. E. A. Cowper. Improvements in apparatus for purifying water and sewage. October 25.

16,981. A. Green. Improved means for purifying water. October 28.

17,552. W. Birch. Improved apparatus for filtering sewage and other liquids. November 5.

17,784. T. Thorp and J. Bentley. Improvements in or connected with the purification of sewage. November 8.

17,898. A. Young. Improvements in asbestos sewerage gas destructor and ventilator or sanitary lamp. November 9.

17,991. G. F. Priestley. New or improved apparatus for treating sewage matter. November 12.

18,148. J. T. Dinsdale and W. B. Kemshead. Improvements in the treatment of sewage and sewage matters, and in the production of manurial products therefrom. November 13.

18,263. R. W. Penrose. An improvement in the treatment of germs. November 15.

18,291. F. W. Brookman. Improvement in the construction of destructors or furnaces for the combustion and cremation of town and other refuse, garbage, or offal, and in the method of disposing of and utilising the products of combustion therefrom. November 15.

C.—Disinfectants.

16,369. J. Orchardson. Improved means of and apparatus to be used for disinfecting, and for destroying vermin, and like purposes. October 17.

16,427. H. Staples, J. Staples, and W. Staples. Improvement in the manufacture of a cattle cleanser, sheep dip, or disinfecting fluid. October 18.

17,042. J. Jackson. An improved disinfectant. The combination and arrangement of substances for the purpose of disinfecting. October 29.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1889.

771. G. D. Wheaton. Means for preserving articles of a perishable nature. November 20.

9861. C. Heinemann. Manufacture of a malt product called "wheat coffee." November 20.

15,526. B. Graf and F. Pickenbrock. Producing ozone-water in which the ozone is retained for a considerable period without alteration. November 20.

16,325. C. P. Goode. See Application, Class XVII.

B.—Sanitary Chemistry.

1888.

16,093. J. G. Lorrain. Method and apparatus for formation of organic oxides, and the oxidation of matter suspended or dissolved in liquids. October 30.

18,568. C. H. Beloe. Purification of sewage and other foul liquids. October 30.

18,719. W. Warner. Means and apparatus for treating refuse. November 20.

18,791. J. Chabanel. Apparatus for separating, filtering, and disinfecting fecal matters. October 23.

1889.

12,623. T. Shaw. See Class IX.

C.—Disinfectants.

1889.

1430. J. Ascough. Manufacturing glazing, antiseptic and washing compounds. October 30.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

16,342. D. C. Simpson. A new or improved composition for treating paper and similar material to render writings or other markings indelible thereon. October 17.

16,930. C. G. Cresswell. Improvements in or relating to toilet paper. October 26.

17,141. D. H. Ferguson. Improvements in the process of manufacturing articles from pulp. Complete Specification. October 29.

17,496. E. A. Blumel. Improvements relating to the covering of various articles with xylonite or celluloid. November 4.

18,090. I. Appletree. A new composition to be used as a substitute for ivory and for other purposes. Complete Specification. November 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,716. C. Morfit. See Class XIII.

1889.

9694. F. J. Cheesbrough.—From H. Pataky and W. Pataky. Preparation of wood pulp for the manufacture of paper cloth, cordage, or other textile fabric. October 23.

14,494. T. Volstorff. Method and apparatus for straining paper pulp. October 23.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

16,197. J. Matthews and H. Johnson. Consolidated perfume. October 15.

16,555. O. Imray.—From W. MacKean, France. Process for obtaining salts of thorium, zirconium, and like metals from their ores or from waste residues of hoods used for incandescent gas lighting. October 19.

16,663. E. G. Scott. Improvements in the manufacture of chloride of carbon. October 22.

16,807. A. W. Rake. An improved anæsthetic compound. October 24.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,627. R. I. Hunter. Dental anodynes or obtundents. November 13.

18,521. E. Schnauffer and Hupfeld. Manufacture of a substitute for musk. October 30.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

17,406. S. V. Dardier. Improvements relating to permanent coloured photographic prints obtained by direct printing from negatives. November 2.

17,773. E. H. Farmer. Improvements in photography. November 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

16,715. A. R. Brown. Printing photographs, especially "blue printing," and apparatus therefor. November 6.

1889.

9012. A. H. Cros. Colour photography. November 20.

13,523. W. P. Thompson.—From C. Spiro. Solutions for developing or fixing the latent images on photographic plates or sheets. November 13.

XXII.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

16,426. J. S. Taylor and S. W. Challen. Improvements in plant for burning special charcoal for the manufacture of gunpowder. October 18.

16,597. T. J. Brown. Improvements in fireworks. October 21.

16,629. J. S. Taylor and S. W. Challen. Improvements in plant for preparing gunpowder carbon, consisting in the application of gaseous or liquid fuel to heat the carbonising vessel. October 22.

17,327. W. L. Roberts. Lighting purposes. A new or improved match, to strike on both ends with ignitive composition on both ends. November 1.

17,353. G. W. Thomas. Improvements in matches, fuses, and the like. November 1.

17,430. A. Walter. Improvements in or appertaining to percussion and time fuses for firing explosives. November 2.

17,474. C. E. Rhodes and A. T. Cocking. Improvements in explosives. November 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,456. W. R. Hodgkinson. Manufacture or treatment of explosives to better control combustion or prevent detonation. November 20.

18,968. E. L. Zalinski and H. J. Smith. Electric primers or igniters for blasting or firing mines, torpedoes, &c. November 20.

18,663. H. S. Maxim. Manufacture of explosives, and apparatus therefor. October 30.

1889.

39. A. Martin. Percussion fuses for explosive projectiles. November 6.

6332. W. H. Scott, L. Paris, and Scott, Lim. Electric fuses. October 30.

14,362. J. G. Gomez and P. Franco. Manufacture of matches of the vesta type. October 23.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

18,141. C. R. Valentine. New or improved apparatus to be used for estimating the acidity of milk, cream, curd, and whey. November 13.

S. Kipping, D.Sc.	A. Wingham.

Please substitute the following for corresponding passage on p. 973, col. 1.:-

An increase in—

Volatile constituents of the coal of	26—40 per cent.
Specific gravity of the gas.....	0.755—0.749
Illuminating power	132—104 $\frac{1}{2}$ litres per 1 candle.
Carbonic acid	1.10—3.13 per cent.
Carbonic oxide.....	6.50—12.00 ..
Methane.....	34.00—37.00 ..
Heavy hydrocarbons of the fatty series ..	2.50—4.80 ..
Tar.....	3.90—5.60 ..
Gas liquor.....	1.50—10.00 ..

A decrease in—

Hydrogen	55.00—42.00 per cent.
Coke.....	71.50—57.8 ..
Temperature, obtained by burning the coke in the retort furnaces = 1,330°—1,220°.	

The author also investigated the other heavy hydrocarbons not belonging to the aromatic series, and found ethylene, propylene and acetylene—the first of these in large quantities. He also examined the illuminating constituents of the gas, and found that, of the total illuminating power of the gas, the heavy hydrocarbons of the fatty series produced 34.9 per cent.; the aromatic hydrocarbons containing 52 per cent. of benzene (down to -22) 15.9 per cent.; while the aromatic hydrocarbons containing 92 per cent. of benzene (-22 to -70) produced 49.2 per cent.

Also the following formula for that appearing on p. 976, foot of col. 2.:-

NOTICES.

Members are hereby advised that the subscription of 1890 falls due on January 1st. Only those members have paid their subscriptions will be entitled to receive Journal.

Orders and orders should be made payable at the Royal Post Office, London, to the Honorary Treasurer, Mr. Cook, and should be forwarded to him at Bow, so it be desired to notify a change of address for the coming new list of members, in which case the subscription should be forwarded together with the change to the Royal Secretary.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or of its Local Sections, are requested to take notice that Rule 41 of the bye-laws, the Society has the right of title of publication for three months of all such papers. Engagement of this bye-law renders papers liable to be used by the Publication Committee, or ordered to be acted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 12.—VOL. VIII.]

DECEMBER 31, 1889.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

COUNCIL FOR YEAR ENDING JULY, 1890.

President: Sir Lowthian Bell, Bart., F.R.S.

Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Harter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

ASSISTED BY THE FOLLOWING STAFF OF Abstractors:

T. L. Bailey, Ph.D.	Chas. A. Kohn, Ph.D.
G. H. Beckett.	F. W. T. Krohn.
D. Bendix.	T. A. Lawson, Ph.D.
E. Bentz.	J. Walter Leather, Ph.D.
Jos. Bernays, M. Inst., C.E.	A. Liebmman, Ph.D.
E. E. Berry.	D. A. Louis.
E. J. Bovan.	W. Macnab.
Bertram Blount.	N. H. J. Miller, Ph.D.
Arthur G. Bloxam.	J. M. H. Munro, D.Sc.
C. H. Bothamley.	H. S. Pattinson, Ph.D.
W. Lant Carpenter.	H. T. Pentermann.
E. G. Clayton.	S. G. Rawson, D.Sc.
Julius B. Cohen, Ph.D.	A. Rée, Ph.D.
C. F. Cross.	F. W. Renant.
A. R. Davis.	Frank Scudder.
W. W. Haldane Gee, B.Sc.	Edward Simpson.
C. Napier Hake.	A. J. Smith, B.Sc.
Oswald Hamilton.	Oscar J. Steinhart, Ph.D.
Bertram Hunt.	A. L. Stern, B.Sc.
C. C. Hutcheson.	D. A. Sutherland.
D. E. Jones, B.Sc.	F. W. Thomas.
W. E. Kay.	Eustace Thomas.
A. J. King, B.Sc.	V. H. Veley, M.A.
F. S. Kipping, D.Sc.	A. Wingham.

NOTICES.

Members are hereby advised that the subscription of 25s. for 1890 falls due on January 1st. Only those members who have paid their subscriptions will be entitled to receive the Journal.

Cheques and orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address for the forthcoming new list of members, in which case the subscription should be forwarded together with the change to the General Secretary.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Harter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roseoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

Editor:

Watson Smith, University College, London, W.C.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 23rd DECEMBER, 1889.

Bartlett, Frank L., Portland, Maine, U.S.A., State assayer.
 Bernard, Jas. jun., 37, Great Western Road, Glasgow, analytical chemist.
 Buchanan, Josh., 118, Keppochhill Road, Glasgow, managing chemist, Pollok Patents Gold Extracting Co.
 Burgess, Wm. T., 1, Ringley Cottages, Reigate, Surrey, analytical chemist.
 Caines, Chas. M., 5, Rochester Terrace, Camden Road, N.W., analytical chemist.
 Carulla, F. J. R., 38, Argyll Terrace, Derby, chemical manufacturer.
 Conroy, Jas. T., The Hollies, Montpellier Crescent, New Brighton, student.
 Dunlop, Robt., Stanrigg Oil Works, Airdrie, N.B., manager.
 Eastwood, Chas., Linacre Gas Works, Bootle, near Liverpool, gasworks manager.
 Fort, Jas., 16, Adelphi Bank Chambers, South John Street, Liverpool, chemical broker.
 Hayes, Jno., 109, Upper Stanhope Street, Liverpool, patent agent.
 Hooper, Ernest F., c/o Burt, Boulton, and Haywood, Chemical Works, Silvertown, E., chemist.
 Hunton, Henry, Greystone Redmarshall, Stockton-on-Tees, chemist.
 Ingle, Harry, Pool, near Leeds, chemical student.
 Johnston, Thos., 149, West George Street, Glasgow, manager Nobel's Explosives Co., Ltd.
 Jourmand, J. L., Sainte Colombe-lez-Vienne, Rhône, France, chemist.
 Keen, Austin, Technical School, Huddersfield, secretary.
 Manhes, P., 30, Rue du Plat, Lyons, France, metallurgical engineer.
 Meggitt, H. A., Chemical Works, Mansfield, Nottingham, glue and manure manufacturer.
 Müller, Geo., 125, Mercer Street, Jersey City, N.J., U.S.A., chemist.
 Pickard, Wm., Stafford Villa, Norfolk Park, Sheffield, manufacturing chemist.
 Ramage, Alex. S., The Stag Chemical Co., Widnes, manufacturing chemist.
 Saeré, Howard C., Breeze House, Higher Broughton, Manchester, chemical manufacturer.
 Shand, Francis J., Aldersyde, Bridge of Weir, N.B., assistant manager Nobel's Explosives Co., Ltd.
 Shaw, Saville, Durham College of Science, Newcastle-on-Tyne, chemical demonstrator.
 Speakman, J. J., 29, Greenway Road, Runcorn, clerk in chemical works.
 Starkey, R. W., Pemman, Hampton Wick, Middlesex, engineer.
 Walker, Ralph W. M., 107, St. George's Road, Warwick Square, S.W., distiller.
 Williams, Geo. G., 102, North 19th Street, Philadelphia, Pa., U.S.A., student.
 Wishart, Jno., 39, St. Vincent Place, Glasgow, mineral oil manufacturer.

CHANGES OF ADDRESS.

Abel, Sir F. A., C.B., Journals to 40, Cadogan Place, London, S.W.
 Barret, E. L., 1/o Willesden Green; 192, Belsize Road, Hampstead, N.W.
 Bell, J. Carter, 1/o Bankfield; Bank House, Higher Broughton, Manchester.
 Brookes, E. A., 1/o Whalley Range; 22, Claremont Grove, Barlow Moor Road, Didsbury, near Manchester.
 Brown, A. E., 1/o Lewisham; Thought Cot, Brentwood.
 Carpenter, H. S., Journals to Beckington House, Weighton Road, Anersley, S.E.

SESSION 1889-90.

1890.

Jan. 6th:—

Mr. C. T. Kingzett. "Hydrogen Peroxide. Its Preservation and Commercial Uses."

Mr. J. W. Lovibend. "An Analytical Tintometer."

Feb. 3rd:—

Messrs A. H. Allen and W. W. Staveley. "On the Properties and Applications of Metallic Compounds of the Phenols."
Mr. Watson Smith. "A New Method of Hardening Steel for Cannon and Projectiles."

March 3rd:—

Dr. H. Schlichter. "Analysis of Textile Fibres and Fabrics."
Dr. L. T. Thorne. "A Review of the Methods of producing Oxygen commercially."

Notices will be found in the Journal and other Scientific Papers.

Meeting held Monday, December 2nd, 1889.

MR. DAVID HOWARD IN THE CHAIR.

- (1.) ON NAPHTHALENE OBSTRUCTIONS IN GAS SERVICE-PIPES; ALSO ON
- (2.) VARIATIONS IN THE PRODUCTS OF THE DESTRUCTIVE DISTILLATION OF DIFFERENT GAS COALS.

BY WATSON SMITH, F.C.S., F.I.C.

Lecturer in Chemical Technology in University College, London.

(1.) *Naphthalene Obstructions in Gas Service-Pipes.*—Many and bitter have been the complaints which have been made about the naphthalene obstructions, and especially by gas manufacturers of the United States. The term is perfectly understood by all gas makers, and only for those less acquainted with the gas industry may it be desirable to offer explanation.

Naphthalene obstructions arise when so much naphthalene vapour occurs in the gas introduced into the mains that the crystalline flakes of that hydrocarbon get into, or condense in the smaller service-pipes, and partially, or at last, and in some cases, entirely stop these up, thus obstructing the flow, and partially or entirely extinguishing the lights. Whole districts have in some cases been thus plunged into darkness from this cause. The cause of the nuisance I have heard attributed to the excessive presence of naphthalene in certain of the varieties of coal used for carbonisation in the gas retorts, and indeed this explanation is more generally current than many chemists are aware of. Thus in a case which came under my observation two years ago, a large heap of cannel on the ground in the gasworks I refer to, was pointed out to me as having stood exposed to a hot sun for some weeks, and it was suggested that coal thus air- and sun-dried would, at the high temperature of carbonising, suffer a more drastic carbonisation, if I may

use the term, than coal in the usual condition of dampness, and hence give off more naphthalene. This deduction of my informant would be more plausible if naphthalene really did exist as such in coal of any kind. I imagine, however, that all steam derived from hygroscopic moisture would have left the retorts before the formation of naphthalene could take place to any extent. Doubtless, however, the fresh charge of coal must cool the retort to some extent, and the formation of steam from moisture present, if considerable, must certainly, by absorption of heat, delay the rise of temperature during the fixed period of gasification, to that usual as the maximum heat. Hence, if we take it that a coal on the average containing a certain amount of moisture is carbonised, and yields gas of usual quality and not excessively burdened with naphthalene, a coal of the same kind but well desiccated may suffer a more prolonged intense heat though the firing arrangements remain constant; and the heat thus attained and prolonged may suffice to materially increase the naphthalene formed. But the hot weather and sun which cause the desiccation of coal exposed to them, will also detract greatly from the efficiency of the atmospheric condensers, and will tend to warm up the rest of the apparatus, and if, through drought or other causes, supply of water to condensers and scrubbers run temporarily short or become warm, or if the usual and normal condensation by cooling be suspended for a time, then great risk is run of naphthalene being carried by the flow of gas into the mains in dangerous abundance, for we have a general concurrence of circumstances favouring deficiency of condensation. Now it is a fact that when a certain ratio exists between naphthalene and the vapours of liquid hydrocarbons, and especially of those of carbolic acid and other phenols, the naphthalene will not sublime so as to deposit in crystals. It seems as if at the moment of the formation of a minute crystal and its deposition from the mixed vapour, a minute quantity of naphtha also condenses upon this point, and the crystal vanishes, so to say, at the moment of formation, a minute drop containing the naphthalene in solution being the result. (That naphtha laden with naphthalene does condense in the mains, is proved by an examination of the street-siphon condensates. See Lunge's Work on Coal Tar, 1887, 28.) But let the proportion of naphthalene increase, and a point will be attained at which sublimation becomes possible and condensation in crystals follows just as in the predominance of snow over drizzle or sleet, snow at last settles, spite of the drizzle. I can give an interesting example of the fact referred to, which was presented to my notice a few years ago. When I visited the first installation of 25 Simon-Carrès coke ovens at Pease's West, Crook, near Darlington, I not only observed that the tar produced was of very high specific gravity, but found that it ran into the tar-well, not cold but milk-warm, and on removing the lid of the well I noticed that the underside, besides the well-sides, were lined with naphthalene to a thickness of about half an inch—the result of sublimation. The atmosphere of the well also smelt strongly of naphthalene vapours—and not of the benzene hydrocarbons, &c. Naphthalene was excessively present in that tar, and the amount of other and liquid constituents was insufficient to exercise any restraint upon the free sublimation of the hydrocarbon. This shows what an awkward intruder naphthalene must be when it once gains, if only for a short period, access to the gas-mains. We then meet with a phenomenon somewhat resembling that of the drifting of snow, and even when the cause has been removed the hydrocarbon will remain in the mains for a considerable time, to be vaporised when warm and redeposited when the weather becomes cold. This peculiarity deceives the gas managers frequently, who think something is continually going wrong, and many vain attempts and useless experiments to remedy the defect are tried. There is thus no doubt that inefficient and insufficient cooling and condensation of the gas before its entry into the mains is a prolific cause of the naphthalene difficulty. I have been recently reminded of Brémont's experiments showing that desiccation of the gas by dry lime is a cure for "any tendency" of such gas to deposit naphthalene. I can only say that though dryness of the gas may put back or delay the deposition till a somewhat higher point of saturation is

attained, it is utterly absurd to say that the cure is an absolute one and that no deposition at any higher point of saturation can take place.

If we trace the progress of the gas after condensation, cooling and scrubbing, we come to the gasometers where it is stored. It is clear that if these be not sufficiently large for the supply required, but also to allow a *certain reserve*, then the condensation and deposit of the naphthalene sublimate from the gas can never take place. During hot weather sufficient condensation then becomes almost impossible.

In preventing naphthalene obstructions all the following points need attention:—

- (a.) The quality of the coals used and the coal mixtures; also the heat of carbonisation.
- (b.) The cooling and condensation of the gas. That sufficient time be allowed for this.
- (c.) The proportion of the condensing and storage plant to the gas supply required.

If there be any doubt (as I understand there is) as to purified gas containing naphthalene, let the doubter read of the experiment of G. E. Davis recorded in this Journal, 1883, 523.

The observation previously noted as to the non-sublimation of naphthalene in presence of an ample quantity of naphtha vapours that are condensing to form liquid products, shows us the benefit of using a mixture of coals containing a good proportion of cannel, which on distillation always yields very liquid tars. The vapours condensing to such liquid products wash or scrub down the naphthalene from the vapours of tars otherwise rich in the hydrocarbon and proceeding from other than true cannels in the coal mixture used.

Let us suppose that naphthalene, in a hot summer, is carried into the mains which are underground, and compared with the apparatus above ground, are cooled. A hot summer will mean plenty of daylight and so little gas consumption, and hence but a slow current of gas through the mains, and the condensers being insufficiently cooled, naphthalene may get into these mains and stop there. In the winter there will be a more rapid current of gas, since there will be a larger demand both in the homes and in places of business, factories, &c., in the early evenings, and if the naphthalene collect and lie about, more especially at bends and angles in the mains, whilst a slow current would not disturb such deposits materially, at the period when some tens of thousands of gas burners are lit up in an early winter's evening, when both offices and homes are inhabited, we may imagine something like a "gust" of gas, if I may use the term, carrying along the naphthalene flakes further and further to the service-pipes and at last causing stoppages in them. Moreover the cold air will aid crystalline condensation in the service-pipes themselves where they reach above ground, for here cooling-surface is relatively much greater than in any part of the system yet traversed. We have not here the conditions for realising the high illuminating value of naphthalene as in the albo-carbon lamp, as has been recently suggested, but the reverse, for though the mains in summer may be cooler than the service-pipes above ground, yet in winter, the opposite will often be the case and the mains be the warmest. In this latter case, we may have slightly warm gas in the mains, to some extent saturated with naphthalene, rising into and through cold service-pipes above ground and exposed to frosty air, the result will be gradual deposition of naphthalene flakes in the service-pipes, especially if the gas be allowed to stand and stagnate there for some time, whereas a considerable use of the gas may not give time for the obstructive condensation.

Hence the frequent observation of stoppages in blind pipes and disused services.

I have now dwelt somewhat at length upon the theme of naphthalene obstructions.

It seldom happens, to the best of my belief, that the observations of the mere practical man are wholly at fault. He may not express himself with scientific accuracy, but there is generally a germ of truth in his utterances which needs, as it were, transplanting, pruning, and cultivation, and then the full truth develops. The statement made to me to the effect that coals differed as to the amounts of naphthalene contained in them, made me pause and consider whether it might not

be possible that what is really the proper way of putting it, is that *different coals carbonised under like conditions yield varying amounts of naphthalene, and also of other products.* This, then, leads us to the second part of my subject, viz.:—

(2.) *Variations in the Products of the Destructive Distillation of different Gas Coals, heated under similar Conditions.*—This idea formed the basis of a series of experiments that was proposed to a large gas company whose customers were grievously plagued by naphthalene in the service-pipes. The company had an experimental plant, the retorts being of cast iron. The proposal was to carbonise 5 cwt. of each kind of coal used, separately, to collect the gas, tar, and gas liquor, and to send me a sample of each tar, in which I was to determine the amount of naphthalene. Each variety of coal of 17 different kinds was thus treated, representing the principal or typical cannels and gas-producing coals in the northern coal-fields of England. Since all these coals passed under the same treatment and through the same retort, the conditions as to temperature of distillation may be regarded as identical.

As more deductions will be attempted from the results of these experiments than those relating to naphthalene, let us now consider the subject in a more general way, and observe what differences are already known as resulting from the carbonisation of different varieties of gas-coals. Many people are not aware of the great influence which the physical properties or, perhaps better, the chemico-physical properties of different coals have upon the products of their destructive distillation, even upon the character of the cokes they leave behind. Thus, you may take three coals, one from the Staffordshire coal-field, one from the North Yorkshire, and the other from the Scottish. Charge all three varieties into three adjoining Simon-Carvès coke ovens, and carbonise under precisely similar conditions. Without taking into account the variations of the other products obtained, you then find three varieties of coke. The first (Staffordshire) of the highly silvery appearance so characteristic of the product from the Beehive coke ovens and in every way answering for blast-furnace use, and indeed from its similarity of appearance exciting no question; the second, less silvery than the Staffordshire product, also successfully used in the blast furnaces, the smaller pieces being excellent for foundry use. The third (the Scottish) gives a loose and more friable product unsuitable for blast-furnace use. Hence the coal-fed blast furnaces of Scotland.

Again, let us suppose a gas retort charged with an ordinary bituminous coal, not distinctly a cannel, but approaching it, and destructive distillation to follow, and again let us suppose it charged with a pronounced cannel coal, and again carbonised precisely as in the former case, or at a still more elevated temperature. In the first case you will get a tar high in specific gravity, and rich in naphthalene and anthracene, but deficient in paraffins and middle oils; in the second case the specific gravity of the tar will be low, paraffins will be plentiful to the detriment of the anthracene, and anthracene and naphthalene scarce. Moreover, the light naphthas with middle oils will be plentiful. The specific gravity of the rectified benzenes in the first case will be 0.880 to 0.890, but in the second it may be about 0.870 or even lower. (See also von Hohenhausen, this Journal, 1884, 74.) In the first case the creosote oil will on cooling partially solidify from crystallisation of naphthalene; in the second, even on cooling crystallisation may not take place. A sample of the clear reddish oil distilled, and the latter small portion taken, boiling at 220° to 250° or thereabouts, may solidify on cooling, but it will present the appearance of a greasy thick mass without much crystalline appearance, and contain a mixture of naphthalene and paraffin. I well recollect the time when Gräbe and Liebermann's great synthesis of artificial alizarin was first effected, and I remember the trouble caused by the anthracenes obtained from the tar from the gas works of the Manchester Corporation, where Wigan cannel was principally carbonised. The difficulty was only overcome by mixing more friable and less bituminous coals with the cannels for charging the gas retorts.

On reading the very instructive paper of Mr. Lewis T. Wright in our Journal for 1888, pages 59—62, I observe that the investigation he there records had for its object the

discovery of the influence of various degrees of heat upon coal during carbonisation in the gas retorts as regards the yield and character of the tar and its products, and the ammonia produced, and also as regards the sulphur compounds other than sulphuretted hydrogen occurring in the gas. The results I offer, on the other hand, have regard to the variation of products with variation of the characters of the gas-coals used, keeping temperature of destructive distillation pretty much constant. As soon as we learn that not only does variation of temperature of destructive distillation affect the yields and characters of products, but also variations in the physical characters of the coals used, we become

impressed with the fact that the question is a more complex one than may have at first sight appeared. With regard to the varieties of gas-coals employed, there were 17 varieties, but as regards the names of them, these I am not able to give, and I prefer also to withhold the name of the gas company for whom the investigation was conducted, though it robs me of the pleasant opportunity of publicly thanking its chairman for allowing me to publish the figures obtained. I now give a tabulated statement of the experimental results of the investigation which will speak for themselves, giving numbers for coals experimented on from 1 to 17, and adding that the experiments were made in 1887.

5	1.196	5.32
7	1.193	5.39
6	1.201	6.00

A glance at the adjoining figures for specific gravity and percentages of naphthalene will show that they fit together remarkably well, rising and falling together. This is more clearly shown in the arrangement on page 953, where the specific gravities are placed in order of magnitude, and it is seen that as these numbers rise so the numbers representing the naphthalene rise, not precisely in all cases, but very nearly so. For the specific gravities of the tars, the Twaddell hydrometer was used and also known volumes were weighed. The second mode may be taken as being about accurate, and the numbers show on comparison with the Twaddell degrees how very inaccurate a method of determining the specific gravity of so thick a fluid it is to use the hydrometer. The Twaddell gravities were taken at the works in the usual manner.

According, then, to the first of the preceding tables, we observe that the coal which, whilst yielding at the given temperature employed a good volume of illuminating gas of good illuminating power, yields also a minimum of naphthalene, is No. 15.

It is now additionally clear from what results have been given:—

(1.) That it is a rational procedure to select a gas-coal or mixture of gas-coals, which will, other circumstances being equal, yield with a good illuminating gas such a fair minimum of naphthalene as will contribute to its illuminating value without the obstructive complications already described; and

(2.) That in the specific gravity of the tar produced we have a fair criterion as to the amount of naphthalene present in that tar (I am here speaking exclusively, of

course, of benzenoid tars), and again also by analogy, some idea as to the relative naphthalene-condition of the gas.

With regard to the effect of high temperature carbonisation irrespective of quality of gas-coal, Mr. Lewis T. Wright in his interesting paper (this Journal, 1888, 61) gives the analysis of a tar obtained from a mixture of Yorkshire and Derbyshire coals distilled at a high temperature. The following result was obtained. Specific gravity of the tar = 1.23. Results of distilling it were as follows:—

	Per Cent.
Ammoniacal liquor	4.39
Crude naphtha	4.11
Light oil
Creosote oil	18.99
Anthracene oil	12.14
Pitch	59.14
	<u>98.77</u>

Mr. Wright remarks "Here the light oils are practically absent, and as soon as the crude naphtha (rich in benzenes) had come over solid naphthalene made its appearance."

Let us now see how nearly this result obtained by Mr. Lewis T. Wright upon mixed Yorkshire and Derbyshire coals will agree with results obtained according to my experience with a Staffordshire coal carbonised also at a very high temperature in the Simon-Carvès coke ovens, and producing, as already remarked earlier in this paper, a coke of very silvery lustre undistinguishable both in appearance and action in the blast furnaces from Beehive coke-oven coke. I have calculated my percentage result of an examination of this tar (made in May 1885) so as to give the same amount of ammoniacal liquor as the tar examined by Mr. Wright. The specific gravity of this tar was 1.2, and on distillation it gave—

	Per Cent.
Ammoniacal liquor	4.39
Crude naphtha (sp. gr. 0.950)	9.70
Distilling over below, (Light oils
but up to 300° C. (Creosote oil	22.70
Above 300° C. Anthracene oil	10.70
Pitch	52.51
	<u>100.00</u>

Thus, there were no light oils and indeed no heavy oils, for the so-called creosote oil was a greasy solid or semi-solid mass of crude naphthalene.

The anthracene "oil" was also a semi-solid mass.

No doubt the temperature here had even exceeded that employed by Mr. Wright in carbonising his coal. The similarity of results is somewhat conspicuous, and the tendency of still higher temperatures has been still further to accentuate the absence of oils, both creosote oils and anthracene oils, as well as ordinary light and heavy oils. Other differences in results will, as already seen, be due to different qualities of the coals carbonised. The crude naphtha obtained as above, and of sp. gr. 0.950, yielded 79.5 per cent. by volume of naphtha and 2.16 per cent. of crude carbolic acid, or 0.14 per cent. on the tar.

I can thus confirm Mr. Wright's observation as to the apparent diminution of the tar acids (phenolic bodies) as well as middle oils with increase of temperature, by these results of mine in 1885, and gas-retort tar generally contains 0.5 per cent. of crude carbolic acid as against the 0.14 per cent. I obtained in this Simon-Carvès oven product. Possibly though, as I have yet to show, neither Mr. Wright nor I sought for the carbolic acid in the right oils, and we did not get all there was in such case. The other results with the crude naphtha were—

Temp. °C.	Per Cent. by Volume.	
Below 100°	1.36	} 63.29
" 110°	8.84	
" 150°	38.08	
" 200°	15.00	
Above 200°	56.71 (chiefly naphthalene).	
	<u>100.00</u>	

The presence of carbolic acid and phenols, whilst the benzenes keep up, and probably increase, confirms Schulze's view (Ann. 227, (1) and (2), 143), that "the primary products of the dry distillation of coals are phenols. These phenols are then at the high or higher temperatures of the retorts split up so as to yield water and high boiling hydrocarbons, whilst another portion of them is reduced to lower boiling hydrocarbons, or finally, with more entire decomposition, into illuminating gas."

Of course, as L. T. Wright observes (*loc. cit.* p. 61), "the gravity of the products in regard to boiling points, increases with increased coal-distillation temperature," and this is easily shown by distilling the same kind of coal at temperatures of increasing elevation and taking the specific gravities of the tars, but my table shows that with approximately the same temperature (the usual gas-making one) and similar conditions, the specific gravities of the tars may differ, if the coals be different in "physical" or chemico-physical character—and differ somewhat considerably.

It is interesting to note that when naphthalene is high in a tar, anthracene is also high, and then usually creosote oil is scarce, and intermediate oils almost or quite absent; but benzenes do not suffer diminution, though if condensation be not good they may be carried off by the gas to a considerable extent. (See G. E. Davis, this Journal, 1883, 520.)

Glancing again at our table, we see great variations in the quantities of tar obtained, which cannot be fully explained by any reference to either volumes of gas obtained, illuminating power of the same, or by reference to the specific gravities of the tars, or the amounts of naphthalene, whether any of these are taken singly or in conjunction. I take it then that the volumes of tar obtained, the carbonising heats being about the same, are functions of the physical and chemical conditions of the coals employed, and hence we may say that in carbonising coal for the sake of aromatic tars, a selection of a special coal among many kinds of gas-coal, may be reasonably sought for. Indeed, I believe the more scientific coal-carboniser has already, to some extent, become aware of this fact, through the experience gained in concentrating attention upon the tar products rather than upon the gas. We find in the table, for example, that whilst No. 9 yields only 7.5 gallons of tar per ton, of sp. gr. 1.187, No. 14 yields 14.8 gallons of sp. gr. 1.170, *i.e.*, nearly double the amount.

If now we arrange the table in the order of the specific gravities of the tars obtained, as on page 953, a curious fact is brought out, *viz.*, that whilst the tar of lowest specific gravity corresponds to the smallest volume of gas obtained of highest candle power, yet it has not followed that naphthalene shall be present in least percentage in that tar, nor has it followed that the tar shall be smallest in percentage amount on the coal carbonised. The yield of tar is good in this instance, and the amount of naphthalene is smallest in amount save one case. The most notable is that at the foot of the table, where, with the tar of highest specific gravity, and gas of low candle power, the yield of gas is highest, and the amount of naphthalene in the tar is highest, yet the amount of tar obtained is also considerable.

It would seem that some coals may be carbonised at a high temperature; a large volume of gas obtained, of rather low illuminating power, and also a considerable volume of tar may be obtained containing much naphthalene, and consequently a thick tar. In short, it would appear, as indeed we have supposed, that some coals have a greater tendency at high temperatures to produce naphthalene and similar high boiling hydrocarbons than others whose tendency is to be more refractory on destructive distillation in this respect, and by preference to form bodies of the phenolic type and benzene hydrocarbons, the phenolic bodies, breaking up in accordance with Schulze's hypothesis, into benzene and other hydrocarbons, and these, or some of them, probably passing off more largely with the gas, increasing its illuminating power, as seen in the table. It must be plain that on the whole the thinner tars, hence containing bodies of lower specific gravity, correspond to gases of highest illuminating power, collaterally produced.

These thin tars are always characteristic of the true canal coals, such as the Wigan canal, notably, and we know that such coals yield highly illuminating gas.

What will strike us most in the table is that in spite of the variations referred to, we see strong evidences of the general rule that with a tar of moderate specific gravity (1·16 to 1·17) we have a large yield of that tar, a good yield of gas of high illuminating power, and a moderate amount of naphthalene with doubtless a good yield of anthracene, and a fair amount of benzene and carbolic acid, whilst with one of high specific gravity, the gaseous volume is larger,

illuminating power smaller, naphthalene (and anthracene) larger, and the amount of tar obtained, smaller. The special deviations from the rule indicate, I take it, differences in the properties of the different coals used, and show that within the general rule, there is room for selective improvement and advantage. The percentages of naphthalene given only, of course, represent the amounts in the tar. That in the gas is considered as gas, and is valuable there so long as it does not deposit and cause obstructions. That in the tar is to some extent an index of what may be expected, other things being equal, in the gas.

TABLE WITH YIELDS ARRANGED IN THE ORDER OF THE SPECIFIC GRAVITIES OF THE TARS.

—	Specific Gravities of Tars.	Amounts of Tar in Gallons.	Yields of Gas.	Candle-Power of Gas.	Percentages of Naphthalene.	Gallons per Ton of Tar.		
						Light Oils distilling below 180°.	Light Oils above 180° with Heavy Oils for Carbolic Acid.	Total.

* Highest candle power.

† Most gas.

‡ Most naphthalene.

I will now pass on to a more special consideration of the tar constituents as obtained from the various coals, similarly distilled, and referred to in the table. By distilling off the crude naphtha and light oil, including some creosote oil, and measuring them, the amounts of these constituents were determined. As crude naphtha, all that coming over on distillation below 180°C. was measured. As to the remaining oil, it may be said that it consisted of light oils, including some heavy oils, and the bulk of it sunk in water. The amounts were measured, and are given in the last table, so as to follow with the specific gravities of the tars, taken in increasing order. It will be seen that as the tars rise in specific gravity, there is clearly a tendency to a falling off in the quantity of crude naphtha and of the light oils; but variations are again very perceptible, depending, no doubt, on the varieties of coal carbonised. The tendency to the falling off in the middle oils manifest above, bears out the observations of Lewis T. Wright (this Journal, 1888, 60 and 61). With regard to the falling off of anthracene in tars of a higher specific gravity than 1·086, my experience does not coincide with that of Mr. Wright; but what I do find is, that with the naphthalene the anthracene also increases, and the specific gravity with increase of both. Moreover, that as the naphthalene increases, the creosote oil gets thicker and the more anthracene is carried over with the creosote oils, and is consequently to be found in them. Hence, to estimate the absolute amount of anthracene in those thicker tars rich in naphthalene, not only the usual anthracene oils

must be examined and extracted, but also the creosote oils, or it will appear as if there were a falling off in the amount of anthracene present, whereas that hydrocarbon has been distributed more widely along with that very widely distributed substance, naphthalene.

There may thus be a kind of change of *locus* in the crude anthracene, and it then appears as if it had been carried or shifted back in part from the higher boiling oils in which it is usually found, and called "anthracene oils," to the lower boiling or creosote oils generally containing naphthalene as the principal solid constituent.

Mr. Charles Lowe, of Reddish, near Manchester, the well-known manufacturer of carbolic acid, informs me that in a precisely similar manner in tars formed by the distillation of coals at very high temperatures, as in the London gasworks, in which the middle oils are somewhat scarce, and the creosote oils thick with naphthalene, the carbolic acid is, to a great extent, carried forward, and is also found mostly in the creosote oils. Thus, years ago, it was considered not worth while to work up the usual "carbolic oils" or "light oils," for carbolic acid in London, because they contained so scanty an amount of phenols. But Mr. Lowe discovered that it was in the thick "creosote oils" of the London tars that they must be sought, and so he took out his patent, No. 3005 of October 11, 1872, on "Treating Coal-gas Tars."

The object of his invention was to obtain phenol, cresol, &c. from the mixed dead or heavy oils of the London coal

tar, or similar tars. He collected about the first 300 galls. of the oils heavier than water, immediately following the crude naphtha and light oils obtained in the distillation of $12\frac{1}{2}$ tons of London gas tar or similar tars, which oils, heavier than water, are at ordinary temperatures in a semi-solid state, owing to the presence of naphthalene, and had not, previous to Mr. Lowe's discovery, been employed for the manufacture of carbolic acid, cresol, and other tar phenols.

Thus we see that the effect of excess of naphthalene with a paucity of middle oils in the tar is to "shift back" the anthracene and to "carry forward" the phenol and cresol into the creosote oils. As regards anthracene, I first showed, in 1869, that this is to be found in varying quantities in all parts of the creosote oils, and could, in some cases, be traced back into the "light oils" (*vide* Lunge's Coal Tar and Ammonia, 1887, page 310). However, though to some practical tar distillers these things may seem strange, they are all, nevertheless, capable of explanation and of being foreseen when once the results of an experimental distillation of the tar have been examined (*vide* Lunge's Coal Tar and Ammonia, 1887, 329—330, also 229—230, with references to the writings of Bossios, Wanklyn, Naumann, and Winkelmann).

But the importance of Charles Lowe's observation and subsequent patent lies further in the fact that not only were the London tars not very poor in carbolic acid, as was then thought to be the case, but they were, and are, on the contrary, actually among the richest in phenol. Besides these, however, benzene, naphthalene, and anthracene, if condensation has been effectively carried out, are also abundant, whilst the less dense tars and those containing more liquid products, like those of the Manchester district, are richer proportionately in cresol and xyleneols, with toluene, and xylenes, and their higher homologues, &c. as well as in paraffins. (I should not be at all surprised if the heavier, the creosote oils, of the Simon-Carvès coke-oven tars do not, like the same oils of the London tars, similarly contain the bulk of the carbolic acid rather than the light oils.) As regards the benzenes in London and Manchester tars, it may be said that though less "light" and "middle oils" come over from the London tars, yet the "light oils" are richer in benzene and poorer in toluene and xylene than the corresponding oils from Manchester tars.

By this latter observation it is not claimed that any constant rule or law can be laid down either by Mr. Charles Lowe or by myself, but it refers to matters based on facts and experience, and so bears evidence to general rule, of course open to certain exceptions.

The London benzenes contain more carbon bisulphide and less paraffins, whilst the Manchester benzenes contain more paraffins and less carbon bisulphide. I take it that the larger quantity of carbon bisulphide is an index of higher temperatures of carbonisation, whilst the increased amount of paraffins and usual greater fluidity of the tars, with greater absence of naphthalene, is by far out of proportion to differences of temperature, and is due principally, though in addition, to the fact that, in Manchester and neighbourhood the coals used for carbonisation are largely composed of rich cannel. When we consider K. Schulze's theory of the production of the benzenes by the degradation of the phenols, Mr. Lowe's patented process of 1872 contains evidence, and is a kind of anticipation on practical grounds of the truth of that theory. For where benzene is rich, we should expect, according to that theory, that phenol is at least, somewhere in the tar, fairly abundant, assuming that the tar is in a normal condition. I am now putting Schulze's theory to some experimental tests, and hope soon to lay my results before the Society.

I cannot conclude without thanking my assistant, Mr. Hamilton, for the intelligent help he rendered in carrying out most of the experiments recorded in this paper.

THE EMPLOYMENT OF CRESOTINIC (OR CRESOTIC) ACID.

BY J. HAUFF.

Read by Joseph F. Fuerst.

THERE is hardly any branch of industry which in proportion to the simplicity of the labour produces such varied *final* results as tanning.

Although dependent upon local and outside circumstances, tanners have the difficult task of combining public taste with the real use which the article serves, and at the same time of maintaining a standard product.

When it became possible by the advance of chemistry to ascertain the influence of water, tanning materials, and lime, upon the manufactured article, the necessity of finding methods and means to reduce the effects of uncertain conditions was felt all the stronger.

The aim of scientific research to predict and regulate effect from cause has lately borne good fruit to the tanning branch of industry; and it is now only a question of time for chemistry with its boundless resources to prescribe the means whereby to obtain a uniform product independent of all outside factors.

The two chief sections of work in tanning—

Firstly, the preparation of hides for tanning;

Secondly, the actual tanning process;

are equally important in their bearing upon the quality of the finished product.

The preparation of the hides is again subject to two divisions:—

(a.) The unhairing process.

(b.) The cleaning process.

It is the last-mentioned with which we have to deal more particularly, and that which has reference to the *new process* for "*freeing skins from lime by cresotinic acid*" as now manufactured.

Every tanner doubtless knows that the hides, in the unhairing process with *lime*, absorb a large portion of it—up to 3 per cent. of its weight in the dry state. The lime remains partly on the outside, fills the pores and apertures of the grain, and enters partly into a kind of chemical combination with the substance of the hide itself.

Experience has shown that lime is to a certain extent a necessity for many kinds of leather, but there are a great many sorts where the presence of lime even in small quantities is positively injurious, preventing the production of certain qualities; so that the regulation of the amount of lime in the hides must be considered as one of the principal operations in the cleaning process.

But it is not alone the amount of lime in itself, which influences the tanning and the quality of the finished leather; it is even more the amount of lime combined with the substance of the hides, which affects the softness, suppleness, elasticity, and greater or lesser density.

The operation which follows the mechanical cleaning of the hide by means of a polishing stone or sand iron, and which removes the lime and makes it fit for tanning, is called "*bating*."

The process of "*bating*," that is "*unliming*," always entails a change in the aggregate condition of the hide, so to speak, and it is therefore the chief aim of the tanner to keep within the desired limits. To this must be added the process of removing the fat in the hide which has nearly always been carried out by the mechanical means following the operation of "*bating*."

The "*bate*" has the same object in the tanning industry—as bearing on the specific qualities of the leather—as the mordants have in the dyeing and printing industries; and it is owing to the recognition of their importance that so much attention is being given to their development.

It is assumed that the purpose of the "*bating*" and its effects are known. I have therefore only to dwell upon the advantages, and the application, of the new method of removing the lime by means of cresotinic acid.

Cresotinic or cresotic acid belongs to the number of the so-called aromatic carbon acids which are derived from the

cresols of the coal-tar methylphenols in the same way as the salicylic acid is derived from the carbolic acid.

By cresotinic acid is understood the isomeric carboxylic acids, obtainable by the action of carbonic acid upon the sodium compounds of the cresol-isomers. The union of cresotinic acid with lime gives a salt of the following formula:—

There are several isomeric cresotinic acids, and all of them have this same power of removing lime.

Being produced from nearly the same raw materials, cresotinic acid, although consisting of several isomers, has nevertheless a decided character of its own. The manufacture of it has attained a high state of perfection, and it is now saleable at a price which offers no impediment to its use in tanneries.

Cresotinic acid has the same antiseptic qualities as salicylic acid—in fact in a much higher degree; its use excludes therefore all the dangers so disastrous with other “bates.”

Its solubility in water is very low. It requires 800—1,000 parts of water and consequently it avoids any formation of skin-destroying concentrated solutions.

A hide or skin may be immersed in a concentrated solution of cresotinic acid containing 22 gallons of water and about 4½ oz. of cresotinic acid, for weeks, without showing the slightest trace of decomposition or destruction, whereas other acids which have been used for the same purpose—such as sulphuric, muriatic, acetic, lactic, and butyric acids, &c., in the same degree of concentration, were seen to destroy the skins in a few days, may even in a few hours.

The reason is that cresotinic acid possesses besides its faintly acid properties certain tanning or hide-preserving functions.

It has, moreover, by its action upon the hide substance known to tanners as “hide gelatin” the great power of bringing the hides down and softening them quite as much as the “bating” with “dungs.”

By reason of its great affinity for lime, and by the formation of crystalline combinations effecting osmotic changes in the interior of the hides, cresotinic acid forms easily soluble basic lime salts which remove the lime very quickly, often within a few hours.

Cresotinic acid thus combines the power of removing lime and softening the hides, saving the tanners (by its subtle influence upon the hides, and on the solution of “glue-forming” substances which are not precipitated by tanning) unnecessary loss of weight and damage to the hides through decomposition.

Cresotinic acid, as an acid, has, moreover, the power of swelling the hides. For this reason it has great value in the plumping of sole leather, and the hide preserving and antiseptic properties are here of the greatest importance.

To “bate” with free cresotinic acid, the same vat or pit that has served the purpose hitherto may be employed (one with a revolving paddle wheel is preferable). It should contain water to the extent of about double the total weight of the hides, not more.

For instance: to 50 heavy “butts” of about 56 lb. each, about 450 to 550 galls. of water are used. To every 250 galls. of water 7 lb. to 9 lb. of cresotinic acid are then taken. To 500 galls. of water about 18 lb. of the cresotinic acid would be taken, previously made in a small vessel into a paste, with about 7 galls. of hot water, until no lumps large enough to resist solution remain (or steam can be turned on to hasten solution).

This solution is then gradually and equally added to the vat or pit with active stirring. This “bating” liquor will then be found acid.

If it does *not* redden litmus paper, the cresotinic acid has been neutralised by the presence of free lime which the vessel contained from previous “bates.” This circumstance necessitates the addition of more cresotinic acid until the desired acid reaction is observable.

The hides or skins ready for “bating” are then put in, and it may here be remarked that with this new method, no

alteration is necessary in the preparation of the hides for “bating” beyond a little more attention to the removal of the “ground” hairs, because these would become somewhat fixed again by the astringent properties of cresotinic acid.

For economy's sake it is also of importance to free the hide from lime in the usual way by the ordinary mechanical means as much as possible, before commencing the “bating” process proper.

Generally speaking the work to be done beforehand is the same with the cresotinic as with all other methods, but this can be materially reduced at the expense of the quantity of cresotinic acid used, and of the duration of the process.

This is, however, a question which every tanner will solve for himself.

The hides or skins now remain in the “bating” liquor, which is kept at a temperature of 80° to 85° F. until they are sufficiently smooth or “brought down,” the liquor being meanwhile frequently stirred or “plunged,”—that is, wherever there is no paddle wheel to keep the whole agitated.

The length of the process depends partly on the thickness of the hides and partly on the condition in which they have been put in. In most cases four to six hours, or even less, will suffice. During the whole time, the hides should be watched until the point is reached when they are sufficiently brought down.

The work to be done after “bating” is the same as by the old process. In most tanneries the hides are cleaned with the polishing stone, and “scud-iron” immediately afterwards. Some tanners put them through the “stocks” and wash them with clean tepid water. Others put them immediately after the “bating” into the tan liquor. There the experience of the tanner will decide which course is best to take.

The “bating” liquor is by no means exhausted with the first batch of hides. On the contrary, several more may be put in; but the water wasted should be replaced by turning on steam or by adding hot water along with dissolved cresotinic acid in proportion to its volume (1:300), and the temperature should be again brought up to 80°—85° F.

It is desirable to avoid the loss of “bating” liquor as much as possible. Experience has shown that with such a “bating” liquor, *i.e.*, 500 galls. water to 18 lb. of cresotinic acid, four lots of 50 hides each can be bated, which at the present price of 1s. 6d. per lb. amounts to 1½d. per hide.

For every further lot of 50 heavy hides, only 4 lb. to 5 lb. of cresotinic acid need be added, and the liquor may be used until it becomes unfit, by accumulation of dirt, &c. It may here be stated that in a well-known tannery, many thousand hides have been treated in the same liquor, after being freshened each time, without the action of the liquor being weakened or rendered useless by putrefaction (as would be the case with dung liquors).

If the hides are required to be brought down exceptionally low and smooth in the grain, then the following method has been shown by experience to be capable of replacing advantageously the dog-dung “bate”:—

Instead of taking free cresotinic acid, its combination with ammonia is taken, and another ammonia salt is added (either chloride of ammonium or sulphate of ammonia); all the other manipulations—the proportion of water to the weight of the skins, the mechanical work before and after the bating—remain the same.

Only the ingredients of the “bating” liquor are different, as the following examples will show.

With 500 *sheep*-skins for glove leather, each skin weighing about 2 lb., 225 galls. of water are taken, and 11 lb. of cresotinate of ammonia. This the tanner can easily make himself, by adding gradually to his solution of 11 lb. cresotinic acid, prepared in the before-mentioned manner with hot water, a watery solution of ammonia (spirits of hartshorn), and stirring it until the cresotinic acid is dissolved, but taking care that the reaction still be acid.

With a solution of 20 per cent. ammonia, only about a gallon of it is required to 11 lb. of cresotinic acid. This solution as well as a solution of 11 lb. sulphate of ammonia or of chloride of ammonia is mixed with the 225 galls. of water brought up to 80°—85° F., the skins are then put in a vat with a paddle-wheel and revolved for about half an

hour so as to be in every way fit for tanning. Close observation is here also necessary to determine the duration of the bating. The skins are treated afterwards according to requirements. Those destined for glove leather are put into clean tepid water, "scudded," smoothed and freed from hairs. Should there be any difficulty about the latter, which however seldom happens, sulphide of sodium in the proportion of 1:1,000 is added to the tepid water, by which the hairs are completely removed.

This "bating" liquor, after being revived each time with hot water or steam, as described, but *without* adding cresotinic acid, can also be used as long as it has any effect:—which, by the way, means about eight lots of 500 skins each, and then *only* about 3 lb. cresotinic acid with the corresponding quantity of solution of ammonia and 1 to 2 lb. of chloride or sulphate of ammonia is added for every further lot of skins.

For other kinds of skins the proportions are the same.

By this method, the "sudding" and working of the skins after the "bating" should not be omitted, because by it the skins are freed from all dirt and fat. Whether it is also necessary to put them through the "stocks" must be left to the choice of each individual tanner.

These methods of "bating" are a complete substitute for the so-called "stink" or "dung" processes in tanning.

The practical results fully bear out the theoretical considerations of their superiority, as is shown by the samples of leather which are here.

It deserves to be mentioned in conclusion that the weight obtained per hide is quite in accordance with the peculiarity of cresotinic acid, which *preserves* the substance of the hide *instead of destroying it*.

A HYDROCARBON FURNACE FOR ASSAYING, &c.

BY GEO. E. R. ELLIS, F.C.S., OF MONTANA.

I HAVE ventured in this paper to give particulars of a piece of apparatus, which my own experience—confirmed by that of many other assayers—has shown to be eminently serviceable as a readily controllable source of intense heat, such as is required by analysts, assayers, metallurgists, and others. This furnace has been before the American public for several years and is therefore past the experimental stage, but, so far as I am aware, it is comparatively or wholly unknown to the English scientist.

Assayers know full well that there are many inconveniences and annoyances necessarily connected with the use of furnaces burning coal or coke; this apparatus, on the contrary, does away with the constant replenishing of fuel, with all dust and ashes, and with a large amount of radiated heat; indeed it may be said that it possesses all the advantages of a gas furnace with the additional advantage that it may be forced to practically any extent without the use of a blower or foot-bellows. Once pumped up—which operation occupies only a few seconds—the blast will continue for a long time without further attention.

The apparatus consists of three parts (each of which may be procured separately), viz.: the tank and blowpipe, the muffle furnace, and the crucible furnace. The tank and blowpipe are represented in Fig. 1. P is an ordinary force-pump at the bottom of which, at A, is a valve which closes automatically upon releasing the pressure from the pump. C is a check valve which closes the inlet to the tank T completely; F is a filling screw for introducing the fuel used, viz., gasoline; V is a vent screw for letting off the pressure when the operation or experiment is finished; H is a pipe leading from the tank to the burner D; E is a burner regulator, terminating in a fine point, closing the orifice of the burner; SS are packing boxes. Upon opening C and pumping a few strokes a pressure is created in the tank and on top of the fluid, forcing it through the tubes of the burner, which being previously heated, vaporise the

gasoline. This issues from the orifice at the end of E as a highly heated gas, and burns as such in the form of a powerful blast. After being once started the heat of the flame passing through the burner D, vaporises the fluid in the tubes and hence the apparatus is automatic.

Fig. 1.

The air which is forced in is not consumed, so that to keep up the blast it only requires a few strokes of the pump occasionally (every half-hour or so) to maintain the pressure lessened by the consumption of the gasoline.

The way to start the blowpipe is simple and as follows: close E, unscrew F and introduce gasoline according to the capacity of the tank. Replace F, close V; open C one or two turns, and give three or four full strokes of the pump P, then close C. Heat the burner by burning some of the gasoline in a suitable vessel (an old scroffier will do well) placed under the burner; when hot apply a match and open E gradually until the action is more or less uniform. The burner is hot enough when no liquid or spray issues from the orifice; if not hot enough let the oil burn slowly until no liquid or spray issues. When sufficiently heated the blast can be made of any desired intensity by the use of the force-pump as above. The mouth of the burner D should be 2—3 inches from the inlet of either furnace, otherwise the combustion in the interior of the furnace will not be complete. To stop the action of the blowpipe, simply shut the regulator E or open screw V, or do both. When not in use, keep V open.

For very high temperatures or muffle work we proceed as follows:—

- (1.) Light as above, and heat inside of furnace to bright redness.
- (2.) Place the burner *against* the inlet of the furnace.
- (3.) Turn out burner flame with E, and immediately turn it on again without lighting it (or simply blow the flame out), when, if the furnace is hot enough, the gas will light *inside* the furnace. When burning inside the furnace, there must be no flame in the burner tube.

The heat can be regulated by the use of E and P.

The tanks are made in two sizes; one contains half a gallon of oil, the other one gallon, and cost (with blowpipe complete) at Chicago respectively, 23.00 dollars and 26.00 dollars.

The muffle furnace is represented in Fig. 2; it is made

Fig. 2.

in two sizes, the one taking a "C" Battersea muffle (8 in. long x 4 3/4 wide x 3 high), the other an "F" Battersea

(10 × 6 × 4). The inlet for the blast is opposite to, and below, the mouth of the muffle, and cannot be seen in the cut. The muffle furnace requires a length of two (not more) of stove-pipe in order to create a draught through the muffle, or they may be connected with a flue; in the latter case a damper must be put in the pipe, for too much draught is prejudicial.

The smaller muffle furnace costs 10.00 dollars, the larger one 15.00 dollars.

Figs. 3 and 4 represent the two kinds of crucible furnace; Fig. 3 being adapted for taking one crucible at a time, Fig. 4 for taking two or four crucibles at the same time. The No. 1 furnace costs 4.00 dollars, and takes a crucible 4 in. in diameter, and 5½ in. deep inside; No. 2 takes a crucible 5 in. in diameter and 6½ in. deep inside, and costs 5.00 dollars; No. 3 costs 7.00 dollars, and takes two crucibles, 4 in. in diameter, while No. 4 costs 12.00 dollars, and can take four No. 10 French crucibles, or equivalent sizes.

Fig. 3.

Fig. 4.

We will now consider some of the conveniences attending the use of this apparatus.

Cost of Running.—This naturally depends upon the local price of the fuel used as the source of heat, viz., gasoline. In a large city, *e.g.*, Chicago or New York, the cost per hour does not exceed 3 cents (1½¢), while 5 cents may be put down as the maximum in out-of-the-way districts. A certain prejudice exists against the use of gasoline, but, from its construction, no accidents can happen from the use of this apparatus save as the result of gross carelessness.

Power of Furnaces.—The heat of the blowpipe can be controlled from that of a Bunsen burner to that required to melt cast iron. Using the crucible furnace, ½ lb. of cast iron can be melted in 15 minutes (furnace cold at the start), or 1 lb. of brass can be melted in 7 minutes (furnace hot at the start). The muffle furnace can be heated to a scorification temperature in 15 minutes. Six scorifications can be performed at the same time in the larger furnace.

Amount of Heat Radiated.—In this respect these furnaces will compare favourably with any in the market. The following readings were taken with the larger size muffle furnace during the scorification of some copper-silver ores:—

Distance from Side (or Front) of Muffle.	Temperature.	Distance from Side of Muffle.	Temperature.
5 ft. (front)...	17° C.	9 in. (side)...	42° C.
22 in. " ...	21° C.	6 in. " ...	52° C.
13 in. " ...	25° C.	3 in. " ...	81° C.
19 in. (side)...	26° C.	1 in. " ...	106° C.
12 in. "	34° C.		

The temperature of an ordinary room at the same time was 16° C.

The general compactness of the apparatus is also a feature in its favour; the larger size muffle furnace stands 14 in. high, is 9 in. wide, and 12½ in. long, while the

corresponding measurements for the crucible furnace taking two crucibles at a time are 10½, 8, and 14½ in. respectively. The whole apparatus can be conveniently used on a table 4 ft. long by 2 ft. 3 in. wide. It is also to be noticed that the burner in Hoskin's apparatus is *outside* of the furnace during the whole of the operation and is, therefore, not subjected to the destructive influence of very high temperatures, as is the case in many forms of furnaces using ordinary coal-gas as a source of heat.

Note.—Since writing the above I find that a muffle furnace is now manufactured sufficiently large to accommodate a 15 in. by 9 in. muffle. This furnace is heated by two blowpipes of the same size and power as described in the above paper.

NOTE ON A NEW TRIPLE BUNSEN BURNER.

BY F. W. BRANSON.

MR. F. W. BRANSON, of Leeds, exhibited a high or low power triple Bunsen burner, a drawing of which is here given:—

Fig. 1.

Fig. 2.

The above combines in one piece of apparatus several gas burners, and is simple in construction and not liable to derangement. Either one, two, or three Bunsen, or luminous flames may be used, and the air or gas supply of either jet can be regulated independently or entirely cut off.

The air regulators are arranged in the usual way. The gas supply is controlled by altering the position of the jets. If arranged as in Figs. 1 or 2, the gas supply is at full. If, however, either jet be rotated in the opposite direction, the gas is gradually reduced and finally cut off. Fig. 2 shows the three jets arranged for a single large flame, but if the jets are separated as in Fig. 1, a much larger area can be heated by means of the three distinct flames which then result.

NOTE ON EIKONOGEN, THE NEW PHOTOGRAPHIC DEVELOPER.

BY RAPHAEL MELDOLA, F.R.S.

IN 1880, when studying the action of nitroso-compounds on phenols, I discovered a nitrososulphonic acid of β -naphthol, which at that time was the first known representative of the class of aromatic nitrososulphonic acids (Jour. Chem. Soc. Trans., Jan. 1881, 40). The compound in question was afterwards utilised as the source of a colouring matter introduced into commerce by the Frankfurter Anilinfarben-Fabrik, Gans and Co., under the name of "Naphthol green B." (Ger. Pat. 28,065, January 19th, 1884). This compound, which was briefly described by Otto Hoffmann (Ber. 1885, 46), is the sodium ferrous salt of the β -naphthol-nitrososulphonic acid referred to, and may have the formula—

according to the view taken with respect to the presence of a nitroso-group or an isonitroso-group in the compound. The colouring matter is of considerable technical value at the present time, and is of interest as being the only known artificial colouring matter which contains iron as an essential constituent, excepting, of course, the well-known iron-cyanogen compounds.

Theory indicates the existence of seven isomeric monosulphonic acids of β -naphthol of which only four are known at the present time. Only one of these is concerned in the present communication, viz., that modification first discovered in 1869 by Schaeffer, and which is best prepared by heating one part of β -naphthol with twice its weight of strong sulphuric acid to the temperature of boiling water till the naphthol is completely sulphonated. One, if not two other, monosulphonic acids are produced at the same time together with a certain quantity of isomeric disulphonic acids, but the chief product under the conditions specified is Schaeffer's monosulphonic acid. It is the latter acid, which on a small scale can best be isolated in the form of its ammonium salt, which gives the nitroso-acid under consideration. In order to prepare the latter it is only necessary to dissolve a given weight of the ammonium or other salt of Schaeffer's acid in cold water together with the necessary quantity of sodium nitrite, and then, keeping the solution well cooled, gradually add hydrochloric acid to acid reaction. The nitrososulphonic acid is at once formed and remains in the solution, imparting to the latter an orange colour. The acid can, if necessary, be isolated in a state of purity as a barium or calcium salt (Jour. Chem. Soc. Trans., 1881, 44).

By the reduction of the nitrososulphonic acid an amidosulphonic acid was prepared, which was isolated and analysed and described in the paper referred to (*loc. cit.*, 47). This acid was the first amidosulphonic acid of naphthol ever obtained, and it is the sodium salt of the said acid which has recently been introduced as a photographic developer under the name of "Eikonogen." As the discoverer of the acid I have been urged to give this note upon its chemical history for the use of English chemists, and in doing so, I think it only fair to add that although the easily oxidisable character of the acid and its salts naturally suggested trying it as a photographic developer, I was not at the time engaged in photographic work, and the idea was never carried out till the substance was actually introduced into commerce for this purpose.

Of the advantages of eikonogen as a developer I do not propose to say anything on the present occasion, since its qualities have been thoroughly tested by photographers, and it is becoming very popular for many reasons, which will be found in the papers dealing with its application. (See for instance papers by Professor G. D. Livinge, Photog. News, September 20th, 1889; John Spiller, in the recently-published "Year Book of Photography" (1890), 124;

also Lyonel Clark and H. M. Elder in the "Photographic News" of December 13th, 1889). Some months after the publication of my paper Griess obtained an amido- β -naphtholmonosulphonic acid which was no doubt identical with the one described by me (Ber. 1881, 2041). He obtained it by reducing the azo-compound formed by the action of metadiazobenzoic acid on Schaeffer's acid. The whole subject has since been thoroughly investigated by O. N. Witt (Ber. 1888, 3468 and 3489), who has not only confirmed and extended my original observations, but has also obtained the three other amidosulphonic acids corresponding to the three β -naphtholmonosulphonic acids made known since the time of my investigations. Witt's amidosulphonic acids were all prepared by the reduction of azo-derivatives of the respective β -naphtholmonosulphonic acids by means of stannous chloride. There are thus known at the present time:—

- (1.) Amido- β -naphthol- β -sulphonic acid, from Schaeffer's acid.
- (2.) Amido- β -naphthol- α -sulphonic acid, from Bayer's (Crocic) acid.
- (3.) Amido- β -naphthol- δ -sulphonic acid, from Casella's F-sulpho acid.
- (4.) Amido- β -naphthol- γ -sulphonic acid, from Dahl's acid.

Of these four acids the first appears to be the most readily oxidisable and therefore the most suitable for photographic development. It is possible that some specimens of eikonogen may contain the acids (2), (3), or (4), but I have not yet met with a preparation in which these isomerides could be detected. With respect to the constitution of eikonogen, I am glad of the present opportunity of being able to correct my earlier statement, because more exact information has been obtained by numerous workers during the nine years which have elapsed since my own investigation. The constitution of the amido-sulphonic acid is, in the first place, dependent upon the constitution of Schaeffer's acid, which was practically unknown in 1881. It was not even known with certainty whether the hydroxyl and sulpho-groups were in the same or in different rings. It has now been shown that this acid is a heteronuclear derivative and the most probable formula is—

It is true that by the oxidation of my amido- β -naphthol-sulphonic acid I obtained phthalic acid, and this led me to the conclusion that Schaeffer's acid was a homonuclear compound. There is now no doubt, however, that the product of oxidation is β -sulphophthalic acid (Remsen and Comstock, Amer. Chem. Journ. V., p. 106; Rée, Inaug. Diss. Bern, 1886), and that the phthalic acid obtained by me from the amido-sulphonic acid was the result of the hydrolysis of this sulphophthalic acid.

It is well known that in compounds which furnish both azo- and nitroso (isonitroso) derivatives the azo-group and the nitroso (isonitroso) group occupy the same position in the aromatic ring. In Schaeffer's acid the most readily replaceable hydrogen atom is undoubtedly the α -(ortho)-atom with reference to the hydroxyl, so that the constitution of these derivatives and of eikonogen is as follows:—

If the first of these compounds be regarded as an isonitroso-compound its formula will be:—

Eikonogen may thus be made either by the reduction of the nitrososulphonic acid or of an azo-derivative of Schaeffer's acid. By the action of diazobenzene chloride upon this last acid an orange colouring matter is obtained, which is met with in the market under the names of "Crocetin Orange," "Brilliant Orange," "Ponceau 4 G.B.," &c. It is one of the oldest known azo-colours, having been described by Griess in 1878 (Ber. 1878, 2197). This compound may be used as a source of eikonogen, using stannous chloride as a reducing agent:—

It would seem more economical, however, for manufacturing purposes to revert to the original method and reduce the nitroso- β -naphthol-sulphonic acid, which need not even be isolated for this purpose, but can be formed by the action of nitrous acid in the manner previously described and reduced in the same solution. The use of aniline can thus be dispensed with, and tin replaced by a cheaper reducing agent, such as zinc dust. The raw material is, moreover, practically a waste product, since the azo-colours obtained from Schaeffer's acid are of but little value compared with those obtained from the other monosulphonic acids of β -naphthol, and it is in the manufacture of some of the latter that Schaeffer's acid is obtained as a by-product. Owing to the readily oxidisable character of the salts of eikonogen, it is necessary, after the free acid has been obtained, to convert the latter into the sodium or potassium salt in the presence of excess of sulphite.

To the numerous coal tar products which have given to chemical industry such a wealth of technically valuable compounds, we can now add this new photographic developer, which threatens to drive the older and related compounds, pyrogallol and hydroquinone, altogether out of the field.

NOTE ON THE FIRST SYNTHETICALLY PREPARED BASE ISOMERIC WITH QUININE.

BY CHARLES A. KOHN, B.Sc., PH.D.,

Demonstrator of Chemistry, University College, Liverpool.

In a recent number of the *Annalen* (253, 251), Wallach and Otto have described an isomer of camphor ($\text{C}_{10}\text{H}_{16}\text{O}$) obtained by treating oil of turpentine in presence of glacial acetic acid with ethyl nitrite and hydrochloric acid. This substance, to which they have given the name of *Pinol*, is a crystalline body possessing a camphor-like odour, and melting at 183° — 184° . Its specific gravity is 0.953, and its index of refraction at 20° is $n_D = 1.46949$. Like many members of the camphor group it readily takes up a molecule of bromine to form a crystalline dibromide $\text{C}_{10}\text{H}_{16}\text{Br}_2\text{O}$. Oxidised with nitric acid or with potassium permanganate carbon dioxide, oxalic acid and terebinic acid result, whence the following constitution is assigned to it as probable:—

Treated with amyl nitrite and glacial acetic acid in the cold, pinol yields a crystalline nitroso-chloride—

which melts at 103° . This body combines readily with ammonia and with amines with the liberation of hydrochloric acid, but whilst α -naphthylamine does not appear to enter readily into combination with the nitroso-chloride, β -naphthylamine does, and the resulting compound is spoken of as of interest, "being the first base isomeric with quinine that has been prepared synthetically." The base is a crystalline body melting at 194° — 195° ; it is insoluble in water, slightly soluble in hot alcohol, readily soluble in ether. Its formation may be represented by the equation—

A somewhat remarkable property both of the base and of its salts is that they are fluorescent. The physiological action of this and of other terpene derivatives is being investigated, but no results have been obtained as yet. As regards the above base, the slight solubility of its salts is a hindrance to its application in this respect. (Private communication from Professor Wallach.)

Having prepared a base some three years ago also isomeric with quinine, it may not be without interest to place on record the relative properties of the two hitherto known isomers of the alkaloid. The substance in question is described in a paper read before the Chemical Society in 1886 (J. Chem. Soc. 1886, 508; also this Journal, 1886, 676). It is a quinoline derivative, and is formed by the action of ethylene dibromide on α -1'-hydroxyhydroquinoline, the latter being prepared by the reduction of hydroxyquinoline with tin and hydrochloric acid. One molecule of ethylene dibromide is heated with two molecules of

α -1'-hydroxyhydroquinoline in a sealed tube to 150° for six hours, and the base is isolated from the hydrobromide first formed by recrystallising this and then decomposing it with sodium carbonate. Its formation may be represented thus:—

The free base forms small glittering prisms, which melt at 233°; it dissolves readily in chloroform and in benzene, with difficulty in hot alcohol, and not at all in water. The basic properties of the substance are only slight, the salts being decomposed by water with the separation of the free base. Owing to the presence of the two hydroxyl groups the body also behaves as an acid, but its acid properties are very weak, in fact, both the basic and acid tendencies of the hydroxyhydroquinoline appear to have been much weakened by the uniting of two molecules in this manner.

Although chance cases of isomerism, such as these, have no bearing on chemical synthesis, it is worth while to note that α -1'-hydroxyhydro-ethylenequinoline approaches much nearer to quinine as regards its chemical constitution than Wallach and Otto's pinol derivative does. Without going into the present state of our knowledge on the constitution of the cinchona alkaloids, there is little doubt that they contain a quinoline ring, most probably in combination with a reduced pyridine ring. (See Armstrong, this Journal, 1687, 482; also Skraup, this Journal, 1889, 474 and 815.) The relation of quinoline to quinine and its allies has been borne out by the preparation of several derivatives of the former possessing physiological properties resembling, to some extent, those of the cinchona alkaloids. Kairin (α -1'-hydroxyhydro-ethylquinoline) has proved the most valuable of these as an antipyretic. This and other febrifuges derived from quinoline contain only one quinoline group, and the above isomer of quinine was prepared with the view of examining the change in physiological action effected by uniting two reduced quinoline rings. The result was that, although α -1'-hydroxyhydro-ethylenequinoline does act as an antipyretic, its action is much weaker than that of kairin, and thus, as far as the evidence afforded by the physiological effect goes, the double quinoline ring is less closely allied to quinine than the single ring compounds are. This is quite in accordance with Skraup's researches on the constitution of quinine, &c., which further go to show that it is improbable that the one quinoline ring contained in these alkaloids is reduced. One important difference in the physiological action of these quinoline derivatives, when compared with that of quinine, is the fact that they are of no value in cases of malaria or of other intermittent fevers.

THE DINSMORE PROCESS FOR THE MANUFACTURE OF COAL GAS.

BY ISAAC CARR.

THE Dinsmore process has for its object the conversion of the tar formed in the distillation of coal into permanent illuminating gas. The gas being generated in conjunction with the ordinary coal gas increases the quantity and the quality of the production over that of the ordinary method of carbonising. The essential points in the process, as it is used at the Widnes Gas Works, are the following:—At the centre of each bed of six retorts (between the second and fourth retorts) an empty ordinary fireclay retort is fixed, called the *duct*, and through this the whole of the gas passes from each retort by means of connecting pipes and suitable taps, before it reaches the hydraulic main, on which there is a heavy seal. In addition to this pipe each retort is connected to the hydraulic main in the usual way. The duration of the charges was six hours, one retort being charged every hour. This renders the supply of gas to the duct continuous. When a retort is drawn, the tap in the pipe connecting the retort with the duct is closed, direct communication with the hydraulic main is thus made and the drawing and charging are effected as usual. After charging, the connexion with the duct is made as before. The tarry vapours passing with the gas through the heated duct are partially converted into permanent gas. The regulation of the temperature in the duct is of great importance, as it is found that if the duct be kept at the same temperature throughout its length the gas becomes attenuated as it reaches the exit pipe, which is fixed at the end opposite the retort lid. Excessive heat would also cause the destruction of some of the ammonia, and for these reasons it is necessary to graduate the heat of the duct by means of suitable brickwork, so that whilst the temperature at the inlet end is a bright cherry-red heat (1,700°—1,800° F.), that at the outlet end (for about one-third of the total length) is a dull red (1,200°—1,300°). Neither the shortening of the duct nor the taking away of the gas from the centre of the duct do away with the necessity for this graduated heating. The ascension pipe from the duct is provided with a water jacket to check the deposition of carbonaceous or pitchy matter, and is connected on to the main by a bridge pipe. At the bottom of this ascension pipe is a lid that can be removed periodically for cleaning purposes.

Thirty-five mouthpieces are now worked at Widnes on this system and the gas supplied to the town consists of two-thirds ordinary gas and one-third Dinsmore gas. It is found that this mixture is quite equal to ordinary gas both as regards its permanency and travelling power, no naphthalene stoppages having been noticed. The extra cost of erecting the Dinsmore plant is 7*l.* per mouthpiece, and the yield of gas is increased in quantity about 10 per cent. and in quality from 4—5 candles. The quantity of tar gasified amounts to about 4 galls. per ton of coal carbonised. By means of this process it has been found possible to dispense with the use of cannel altogether at the Widnes works, and a mixture of 75 per cent. of Arley coal together with 25 per cent. of Arley slack, which mixture is delivered at 7*s.* 4½*d.* per ton, has been found to yield 9,600 cub. ft. of gas of 19-candle power, per ton, one-third of the gas being carbonised by the Dinsmore process, as above stated. The mixture of coal and cannel formerly employed cost 11*s.* 9*d.* per ton and yielded 10,600 cub. ft. of gas of 18-candle power per ton. Deducting the lower value of the coke from the coal now employed (1*s.* per ton), and making due allowance for the increased cost of the plant, depreciation in value of and lower yield of tar and increased heating required for the retorts worked on the Dinsmore system (about 5 per cent.), the total saving through the adoption of this process will amount this year to 1,758*l.* 13*s.*, a sum equal to 4½*d.* per 1,000 cub. ft. on the quantity of gas sold. In this estimate no account is taken of the increased illuminating power of the gas (from 18—19 candles), which can be put down at least at 528*l.* The following statement gives full details as regards the relative costs of the Dinsmore and the ordinary process of gas making:—

STATEMENT SHOWING THE WORKING BY THE ORDINARY PROCESS ONLY.

	£	s.	d.	Cub. Ft.	Cub. Ft.	£	s.	d.
Coal 8,981 tons, or 85 per cent., at 11s.	4,339	11	0	Gas produced, at 10,500 per ton = 112,000,000 at 2s.	11,200	0	0	
Cannel 1,585 " 15 " " 16s.	1,268	0	0	Tons Coal. Cwt. Coke.

Balance in favour of the Dinsmore process 1,758 13 0			

The Dinsmore process is not applied to the whole of the retorts in use in order to allow of the regulation of a proper proportion between the quantity and illuminating power of the gas and the quantity of the residual products.

The cost of labour is somewhat less, the yield of ammonia slightly greater than when gas is made in the ordinary way.

The following table, giving the composition of pure Dinsmore gas, compared with that of one-third Dinsmore gas, is taken from a report on the process by Mr. Wm. Foster, M.A. :—

TABLE GIVING THE CHEMICAL COMPOSITION OF SAMPLES OF GAS MANUFACTURED AT THE WIDNES GAS WORKS BY THE DINSMORE PROCESS.

[All quantities are expressed in volumes per 100 volumes.]

Description of Gas.	Crude Dinsmore Gas, made Nov. 12, 1889. Lighting value by "G" Argand, after Purification, 21'8 Candles; sp. gr. '424 (dry air = 1).	Purified Dinsmore Gas, taken from Experimental Holder Nov. 11, 1889 (Gas made the previous day). 11'66 Candles; sp. gr. '428.	Town Gas, made Nov. 11, 1889. Illuminating Power, 18'66 Candles (one-third is Dinsmore gas); sp. gr. '420.
Carbonic acid gas (CO ₂)	Volumes per 100 Vols. of Gas. This includes (2'75) H ₂ S after purification.	Volumes per 100 Vols. of Gas. 0'23	Volumes per 100 Vols. of Gas. 2'09

As regards the tar obtained by the Dinsmore process of carbonisation, it was found to contain 10·3 per cent. of water and 3·6 per cent. of light oils, whilst the tar as supplied from the works, where gas consisting of one-third Dinsmore gas was furnished, contains 4·1 per cent. water and 6·2 per cent. of light oils. Mr. Foster states that there is no doubt that the increased illuminating power of the gas produced in this process is in a great measure due to the rendering of some of the more volatile portions of the tar permanently gaseous, but he does not attribute it entirely to this.

A discussion ensued in which the Chairman, Messrs. Thompson, G. E. Davies, Parnell, Glover, King, Norman Tate, McDonald, Dr. Naef, and Dr. Kohn took part, the meeting closing with a cordial vote of thanks to Mr. Carr.

Meeting held at Victoria Hotel, Manchester, on December, 1889.

MR. IVAN LEVINSTEIN IN THE CHAIR.

SECTIONAL COMMITTEES OF CHAMBERS OF COMMERCE.

BY IVAN LEVINSTEIN.

IN opening this session, it is not my intention to bring before you, as has been done sometimes on previous occasions, a statement of the general progress or special applications of the science with which we are more intimately connected. We now possess such a quantity of excellent scientific and technical literature, both in English and German, accessible to every student interested in these subjects, in which all new facts and the matters bearing upon them are carefully reported and systematically arranged, that it appeared to me unnecessary to occupy your time with a retrospect of the progress achieved in chemistry and technology during the past twelve months. I thought that the short time at my disposal might be more usefully employed in briefly referring to certain questions, which, although outside of the immediate range of science, have yet an important bearing on the development of industries in which we are all more or less engaged.

Those who are thoroughly conversant with the details relating to these industries in both England and Germany cannot close their eyes to the fact that the progress which is at present being made by our great rivals is greater as regards development and expansion than our own. Various reasons have been assigned for this fact; amongst others the superior technical education of our Continental competitors. No doubt this question of technical education is one of great importance, but thanks to the efforts and labours of some of our most eminent educationalists, this question is now fully appreciated and understood by the people of this country. A considerable number of new technical schools have been established, and the movement is still going on, and before long we may be able in Manchester to boast of one of the largest and probably best equipped technical institutes in this country or elsewhere. We may therefore safely leave this matter in the able hands of those who have hitherto taken such a prominent part in the movement, and of those to whom the management of the various educational institutions has been confided.

In my opinion, however, we must not *only* look to superior technical education as a means of developing these industries,

Manchester Section.

SESSION 1890.

Jan. 7th:—

Dr. J. B. Cohen. "Communications from the Owens College Laboratory."

Mr. J. A. Wilson. "The Rates of Distillation of Acetic Acid."

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

but we must also keep in view the necessity of making the public more thoroughly acquainted with their importance, and thus interest the mercantile class generally in the removal of any possible burden or disadvantage under which they may be labouring.

The rate of expansion of the chemical industries is a true gauge of the rate of progress and development of many other industries; yet, strange to say, the chemical and allied industries, and the value to the community of a skilled chemist, are comparatively less thought of and appreciated in our own than in any other European manufacturing country. No doubt our merchants and traders have been influenced to a large extent in the appreciation of the importance of those industries by the value of our export in chemicals and similar products compared, for instance, with the value in cotton goods; but even then we might have reasonably presumed that those industries ought to have at least received their proportionate share of attention. Such, however, has not hitherto been the case. But I go further than this, and am of opinion that it would be quite fallacious to estimate the importance of these industries by the exact amount of wages paid to the workpeople, or by the exact amount of the value of their exports. In estimating their true value we must bear in mind that in some measure, and often very materially, they assist or even bring about the export of some of our staple productions. It is, therefore, the interest, not only of those engaged in these industries, but of all classes of the trading community, and, not least, of those engaged in our staple branches, to encourage their development and assist in removing such disadvantages as may operate to prevent their free and untrammelled growth and expansion. The export, for example, of our bleached, dyed, printed, finished, and sized goods depends in no small degree on the good quality and cheapness of chemicals and dyes and similar products.

Only recently some facts came under my notice which prove how matters apparently very trivial may exercise an influence on the export of our cotton goods. Some two or three years ago a certain red colouring matter was introduced amongst the Turkey-red and other dyes in Lancashire and Scotland, not as a substitute for Turkey-red, but as a new colour, possessing the advantage of being, if not so fast, at any rate more brilliant and far more easily applicable to the colouring of cotton fibre. For a time a very good trade was done with India in the yarns coloured with this dye. This trade has now almost entirely ceased, for the reason that an enterprising firm sent one of its representatives to India, introduced this colouring matter over there, and showed the native dyers its ready applicability to cotton. A loss has thus been inflicted not only on some of our dyers, but also on certain manufacturers of these special yarns.

Again, let America only abolish the duties on chemicals, drugs, and dyes, and I have no doubt that she will at once become a formidable competitor in at least some classes of cotton goods, not only in certain foreign markets, but probably even in our own home market.

It cannot therefore be too often repeated, that in estimating the true value and importance of these industries, the influence which they exercise on the development and success of other industries must be taken into account. It was with the object of securing a better appreciation and representation of the needs and requirements of the chemical and allied industries, that at the very commencement of the present year I recommended, in an article in the New Year's issue of the Chemical Trades Journal, the establishment in our Chambers of Commerce of sectional committees to be selected from experts possessing a special knowledge of the various industries and trades carried on in the neighbourhood, to whom all questions of public interest connected with those special industries should be referred for consideration; that these committees should then hand in to the Board of Directors a report upon any question thus submitted, together with their recommendations, such reports to be published in the Journal of the Chamber and elsewhere, if deemed of sufficient interest and importance.

On the 18th of January a well attended meeting of gentlemen interested in the Chemical and allied industries

was held at the Victoria Hotel in this city, to consider the desirability of attaching to the Manchester Chamber of Commerce a sectional committee representing those industries. At this meeting the following resolution was passed unanimously:—

"That it is desirable that a committee be attached to the Manchester Chamber of Commerce, charged with the duty of representing the interests of the Chemical and allied industries, such section to be subject to the supervision of the Board of the Chamber."

A Memorial was drawn up and adopted by this meeting, and a deputation appointed to wait on the Board of Directors to express the views of the meeting. This deputation, representing the industries connected with Dyeing, Printing, Bleaching, Paper-Making, India-Rubber, Chemical Engineering, Chemicals, Coal-Tar Products, Colours, Dyes, Pharmaceutical Preparations, Drugs, Oils, and other allied industries, was received by the Board on January 28th this year, and, after a lengthy discussion, the late President, Mr. Gaddum, assured them that the Board of Directors would do everything in order to further their object. On this assurance, a committee, representing the Chemical and allied industries, was elected and at once set to work. A number of meetings was held to draw up objections to the Revised Classification and Revised Schedules of Railway Rates and Charges, and also a classification was suggested of chemical and similar goods based on rational commercial and scientific principles, and the objections and suggestions were lodged by the Chamber in due time with the Board of Trade. Unfortunately, however, it was found at the time that the rules of the Chamber did not provide for the establishment of such local sectional committees.

This difficulty was eventually overcome by the resolution passed on the 4th November at a special general meeting of the Chamber, and which resolution has been confirmed on November 27th, by which the establishment of such local sectional committees was sanctioned.

Now this result, which I believe will be of the greatest benefit, not only to the industries located in this neighbourhood, but to those all over the country, is primarily due to the efforts of the Manchester Section of the Society of Chemical Industry, and I would suggest that all the sections of our influential and representative Society should endeavour to get chemical sections established in connexion with their Chambers of Commerce, where such do not already exist.

It is a matter of satisfaction to me to announce that under the new rules a strong committee representing the Chemical and other allied branches of manufacture and trade in this neighbourhood has been formed, and approved of by the Board of the Manchester Chamber of Commerce. It will be in the power of this committee to render considerable assistance in the development of the Chemical and allied industries in the district, and in making Manchester not only the most important centre in England, but in the whole world. That such an achievement is within the bounds of possibility, and even of probability, must be obvious if we consider, firstly, that Manchester, or Greater Manchester, is already the largest consumer of chemicals, drugs, and dyes of any city in the world; secondly, that the principal materials are close at its door; thirdly, that its already favourable geographical position will be still further enhanced by the Ship Canal.

There will be a great deal of work awaiting this committee, and the question whether our patent laws in their present form are best calculated to assist the development of our industries may probably form an important subject for its consideration. This question ought to be regarded as a purely economic one, and as lying entirely outside of party politics, because the principle of granting patents is and has been recognised by all parties, fair traders as well as free traders; and however obnoxious it may be to many people, no better means have yet been devised of rewarding inventors and stimulating the inventive faculties of the people generally, than by granting such monopolies. But, as desirable as it is to reward the inventor for that which he has really invented, and which has been ascertained by experiment to be a *bonâ fide* invention, by granting to him, for want of something better, a monopoly of production and sale for a

number of years, there ought to be sufficient safeguards and restrictions for preventing the abuse of the privilege, otherwise the very object for which patents were really established in this country would be defeated, viz., that of benefiting industry. That this was the principal object of the founders of these laws is evident from the original Act of 1653, wherein it is stated that such privileges or letters patent are only granted provided "that they be not contrary to the law nor mischievous to the State by raising prices of commodities at home or hurt of trade or generally inconvenient." These laws have been extended, altered, and amended from time to time, and must necessarily be further amended in the future in such a manner as to adapt and fit themselves to the progress of discovery and of science, and its application to the arts, trades, and manufactures. Experience has been gained in the practice of these laws in our law courts for more than 200 years, and the wants and requirements, both of inventors and of those who are engaged in trade, have been argued and considered, with the result that a large number of precedents have been established, which have also no doubt been effectual in some instances in providing certain restrictions for preventing the abuse of privilege and protecting the interests of inventors.

Unfortunately, however, all this experience has been gained almost exclusively in connexion with mechanical cases, and comparatively only very few chemical cases have been established: moreover, in the establishment of these the law and the precedents have frequently to be strained in order that conclusions might be drawn from the latter, and that the law might be adjusted to chemical cases. These difficulties are daily increasing, in consequence of the rapid progress made in the domain of chemical science, and the equally rapid application of the new discoveries to the arts, trades, and manufactures. For example, such expressions as isomerism, homologues, or even as chemically analogous bodies, chemical equivalents, and chemical combinations were absolutely unknown quantities to the founders of our patent laws, and are probably yet so to most of our legislators and eminent judges. Small as these matters may appear to outsiders it is in the legal interpretation and application of the meaning of such words and similar expressions that the greatest confusion and bewilderment must necessarily prevail in the minds of those who have to decide such cases, when searching for precedents in decisions given in mechanical cases, where clever counsel and shrewd professional experts can add confusion to confusion, and thus prevent justice being done to either inventors or alleged infringers, as the case may be. There are moreover many other points in our present patent laws and in their applicability to chemical inventions which will deserve careful attention; for instance, the examination of patent specifications before granting provisional protection, the opposition to the final granting of patents, the extent to which amendments are permissible in chemical patents, &c., after the final specification has been granted. The new committee may do, therefore, most valuable work in endeavouring to suggest amendments which shall make our patent laws properly applicable to the wants of modern chemistry and prevent the abuse of privilege, so that equal justice may be meted out alike to true and *bonâ fide* inventors and to the industries at large. I freely state my opinion that the patent laws, in their present form, are not by any means in harmony with the spirit of the original Act or statute, which is fair and just to all, and are not only hurtful and inimical to the development of the chemical industries in this country, but also to native inventive talent engaged in chemical research. It is, however, not the object of this brief address to go into minute details, but I shall have pleasure in furnishing the new sectional committee of the Manchester Chamber of Commerce with material and facts in support of my assertion.

Other questions will also no doubt deserve the careful attention of the new committee, such, for example, as the correct classification of chemical products, based on some rational principle, in lieu of the present haphazard and in many respects absurd system adopted by railway companies: the question of packages, distribution and sampling of goods, uniform methods of analysis of commercial products,

abolition of duty on pure alcohol and pure wood-nap'tha used for manufacturing purposes, fire insurances, comparative tables of inflammable and combustible substances, publication of consular and other reports concerning these industries, &c.

In addition to these more or less purely commercial chemical questions, special attention ought also to be paid, amongst other things, to the dyeing of fancy coloured yarns. This trade, which formerly was chiefly carried on in Scotland, has been transferred, within the last few years, to a large extent to Manchester, and promises to become an important feature of our local trade, principally in fancy yarns exported to India. In view of the fact that this committee includes some of our leading dyers, it may safely be assumed that certain rules will be proposed to the Board to guide the trade in determining such points as shrinkage of yarns in dyeing, counts and weights made up by dyers, weights of bundles of dyed yarns, average length per hank of coloured yarn, &c.

The Society of Chemical Industry and its various sections, by co-operating with the sections of our Chambers of Commerce representing the Chemical and allied trades, will be in a position materially to aid and assist the latter in their arduous and important labours, and whilst our Society will continue its excellent work in disseminating technical knowledge and information amongst its members, the sectional committees of the Chamber of Commerce will look after their commercial interests, and endeavour to protect the legitimate rights of all traders.

I sincerely hope that the step in advance thus taken by the Board of the Manchester Chamber of Commerce will lend a new impetus to the development and expansion of industries in which Great Britain, as long as it adheres to the principle of free trade and supported by her natural resources, must and will take the lead of every nation on the globe.

DISCUSSION.

Dr. SCHUXER pointed out that the great difference between English and Continental systems was well exemplified in France, where novelties were not left to individuals to investigate, but were at once taken in hand by the Chambers of Commerce. He had in his library a little work on Chinese green, which was published by the direction and at the expense of the Chamber of Commerce of Lyons. Treatises such as this were of great value. He hoped that the sectional committees referred to by the Chairman would in a similar manner be able to order reports on such new products as might from time to time be met with.

Mr. GEORGE E. DAVIS said, as one who had taken some part in the formation of sections of the Chemical and allied industries in the Manchester Chamber of Commerce, he was surprised to find how very few chemical people there were on the list of members. When they looked for supporters in order to bring the matter before the Board in such a way as to ensure their proposals being entertained, they had to enlist the services of outsiders in order to secure a hearing. If any good was to be done the chemical manufacturers of the district must understand that they were important factors in the matter, and that not only their support but also their attendance at meetings would be required. With regard to the patent laws, it was only such committees as it was proposed should be formed by the Chamber of Commerce that could tackle this question. This was borne out by the fact that the patent laws committee of the Society of Chemical Industry actually had a clause before them impressing the Government of the day with the necessity of fixing a time within which a patent must be worked when taken out by foreigners abroad, but there were such conflicting interests at stake that this clause was struck out altogether. Thus they need not hope for any amendment until the question became purely a commercial one.

Mr. H. GRIMSHAW thought that before chemical manufacturers in the district could expect any advantage to result from these sectional committees of the Manchester Chamber of Commerce, they would require to become members of the Chamber. The reason chemical manufacturers had not hitherto associated themselves with the

Chamber was simply that it did not appear to be of any service to the chemical trades. The Chambers did not offer any encouragement to any trade to associate itself with it except the cotton trade, which of course was fully represented, owing to the fact that Manchester was the great centre of that particular industry. Seeing that in that district there were perhaps a greater variety of industries than in any other, excluding perhaps the Metropolis, he thought the Manchester Chamber should have a greater number of these sectional committees than any other Chamber in the kingdom. Perhaps the point of difference alluded to by Dr. Schunck between the work done by the Chambers of Commerce in this country and those abroad arose from this very fact, namely, that we had not these sections of specially qualified men to make exhaustive reports on special branches of industry. With regard to the subjects to be taken up by this new sectional committee of the chemical trades, the Patent Laws as affecting chemical industries in particular deserved the first consideration, inasmuch that at the present time they were in a very chaotic state in several important points. In many respects they actually favoured the foreigner at the expense of the Englishman, in so far that they gave him a monopoly in this country without in any way binding him to work his patent here, and in this respect a radical change was required. The next most important matter for consideration would be the railway rates and charges on chemical products, as it was quite impossible for any one except those engaged in the trade to develop a proper classification of chemical goods.

The view generally taken by outsiders as to the importance and magnitude of the chemical trade was not altogether a fair representation of the immense amount of chemicals which were used in this country and exported in the various forms of dyes on cotton goods and yarns; the pigments in paper, the chemicals introduced into india-rubber goods; the ingredients of the size and finish on cotton, woollen, and silk goods, &c. All these chemical products were omitted in the statistical summing up of the chemical products produced in and exported from this country.

The establishment of these sections of Chambers of Commerce would vitally affect the trade of this country in the future for good. They were periodically alarmed by a contemplation of the returns showing the increase made by foreign countries in the chemical and other trades, and it would be the work of proper Chambers of Commerce through their sections to justify or to minimise these fears. For his own part he thought that when they had done all they possibly could, they should not have the same leading position that they had enjoyed in the past, they should not lead to the same extent, and they could not expect to retain such a pronounced advantage for ever; but by using their facilities to the utmost and by seeing that they were at all events as fair to themselves as to outsiders, they should still keep in the front rank in the commercial battlefield.

He hoped that the members of the Society of Chemical Industry would do all they possibly could to support the Chamber of Commerce by becoming members and by making their presence felt when those matters affecting the trade were brought forward for discussion.

Dr. GROSSMAN said, as the Chairman had pointed out in his address, it seemed a strange thing that so many law-suits which involved technical questions should be decided by judges and argued by counsel who knew nothing of chemistry. At the same time they need not expect any reform in these matters so long as the legal element was so strong in Parliament. It seemed to him that these sectional committees might settle most of these disputes at much less expense.

Mr. ELIJAH HELM, Secretary of the Manchester Chamber of Commerce, said the idea of forming sectional committees had long been entertained by many members of the Board, and the desire had grown. It had been felt that the Chamber with all its traditional influence and experience—and it had had a great deal of experience—should be more widely useful considering the enormous expansion and multiplied variety and complexity of industries in the great district of which Manchester was the centre. They knew

how great had been the difficulties which had to be surmounted before the arrangements which had been made could be carried out, and it now rested with the members of the various industries to assist the Board by joining the Chamber and giving it the advantage of their experience.

He gleaned from what had been said that one of the most pressing questions affecting their own department was that of the reform of the patent laws, and he thought he might venture to say that if some definite line of policy was suggested by the committee it would receive the hearty support of the Board. They had a good case, and it had been made more forcible by what had been said that night. One other subject which had been referred to was the frequent law-suits and the expenses of litigation. The Chamber had tribunals which had already at little cost decided trade disputes, some of which had been referred to them by the law courts; and when their sectional committee started work the tribunal could be strengthened by the addition of competent members especially conversant with each branch of trade, to whom these special questions might be referred. Certain bye-laws would have to be framed for the regulation of the sectional committees and the organisation committee of the Board are meeting this week for this very purpose. They would, therefore, see that no time was being lost in meeting their wishes.

The CHAIRMAN, in reply to Dr. Schunck, stated that the organisation of the Chambers of Commerce on the Continent was very different to that of our own Chambers, and it was the knowledge of this fact which led him to suggest the formation of sectional committees in our own Chambers, which would be able to deal with questions appertaining to special trades others than cotton, such as chemical and similar products, metals, food-stuffs, &c. He had endeavoured to point out that the chemical industries could not be judged solely by a standard of pounds, shillings, and pence, but by the influence which they exercised in the development of other trades, and he ventured to rely on the hearty co-operation of the members of the Manchester Section of the Society of Chemical Industry with the new section of their Chamber of Commerce.

MR. T. W. STUART IN THE CHAIR.

ON THE DETERMINATION OF MINUTE QUANTITIES OF ALUMINIUM IN IRON AND STEEL.

BY JOHN E. STEAD, F.R.C.

SINCE the discovery that aluminium or ferro-aluminium when added to molten steel and iron greatly improves their flowing properties, producing castings practically free from honeycombs, the iron and steel analyst has been called

It is no wonder that the estimation of sulphur in pyrites, a commodity of which annually at least two million tons are got, at least one million of which is sold by analyses, should be very carefully treated. Although the value of pyrites has so much declined since, some years ago, Messrs. Chance first proved the possibility of recovering the entire sulphur of alkali waste, yet the sums involved in this trade, owing to the immense quantities concerned, are very large, and warrant the demand of accuracy in establishing the sale price of any large parcel of pyrites.

For a number of years the methods of decomposing pyrites for analysis by fusion with alkaline carbonates, nitrates, and so forth, have been in most laboratories replaced by decomposition in the wet way, employing the mixture first proposed by me, namely, three or four parts of nitric acid of sp. gr. 1·4 to one part of strong hydrochloric acid. This operation is much more easily carried out than the decomposition by fusion in the dry way; it succeeds with ordinary care even in the hands of less experienced chemists, who would not obtain sufficiently accurate results by the process of fusion, with its concomitant risks of loss by spurning in getting the mass out of the crucible, &c. It takes altogether only about half the time of that required for an analysis in the dry way; no platinum crucibles are spoiled, and no chance of error is introduced by the sulphur contained in coal-gas. The fact that the decomposition in the wet way leaves untouched the sulphur of barium sulphate and, apart from a very slight quantity, that of galena, is precisely a recommendation of it in comparison with the dry method, which estimates also the useless sulphur of the first-mentioned minerals.

This, no doubt, explains the preference shown by most practical chemists for the decomposition of pyrites in the wet way. As practised universally before, and very frequently even now, that method certainly contains a source of error in the large quantity of iron present. It had long been known that it is hardly possible, when precipitating barium sulphate in solutions containing iron, to obtain a precipitate free from the latter, and tedious prescriptions were made for purifying such precipitates after ignition, which, I am bound to say, could not be carried out by any but very skilled operators without incurring mechanical losses, and which, moreover, rarely succeeded in their object. I have shown in one of my former publications (*Zeits. Anal. Chem.* **19**, 419) that it is quite possible to get the iron out of the precipitate in the wet state by means of energetic treatment with strong hydrochloric acid; but this causes the dissolution of somewhat considerable quantities of barium sulphate which can be recovered only by circuitous and lengthy methods.

Fresenius (*Zeits. Anal. Chem.* **19**, 53) has treated the point in question somewhat in detail. He states that by the wet method as carried out according to prescriptions in my "Treatise of the Manufacture of Sulphuric Acid and Alkali" results were obtained about 1 per cent. lower than by the (lengthy and troublesome) dry method described by himself, which he ascribes to the solubility of barium sulphate in ferric chloride. He certainly neglected to take into account the fact, pointed out by me both before and after, that the dry method includes the sulphur of heavy spar and galena, purposely left out by the wet method; this would no doubt have reduced the real difference between his and my method to a much smaller figure. But I do not doubt that there *is* such a difference, for my own very careful experiments, described in the above-mentioned paper, did show an average error of 0·18 per cent. in the wet method as practised *then*, in comparison with the results obtained by the improved process which I had worked out in consequence of Fresenius' objection, and which consists in removing the iron by means of ammonia previously to precipitating the sulphur, and operating in such manner that no trace of sulphuric acid is left in the ferric hydrate, and that the analysis is detained only about an hour by this additional operation, as we shall see hereafter.

The cause of the error incurred in the presence of salts of iron has been fully investigated by Jannasch and Richards (comp. the abstract of their paper in this Journal, 1889, p. 819), and has been satisfactorily explained by them. They have, however, arrived at a very misleading conclusion, namely, "that 'Lunge's method' is not sufficiently accurate, and that the dry way prescribed by Fresenius should be employed for all purposes requiring scientific precision." Jannasch and Richards had made a serious mistake in conducting that part of their investigation which refers to a comparison between the methods of Fresenius and my own. They had entirely overlooked the fact that I had, nine years before them and in a paper quoted by themselves (the same which I have mentioned above), modified my method in the above-

mentioned manner, so as to do away with all objections to the wet way of decomposing pyrites by removing the iron by precipitation with ammonia. It is this which is commonly known as Lunge's "new method," which is contained in the "Alkali-Makers' Pocketbook," and which has been adopted in Germany as binding between buyer and seller; but upon *this* method, having omitted to notice it, Jannasch and Richards did not make one single experiment. On the contrary, after I had drawn Professor Jannasch's attention to this fact, he himself tried my "new" method, and expresses himself upon it as follows (*J. prakt. Chem.* [2], **40**, 236):—"By the previous precipitation of the iron at a moderate heat with a slight excess of ammonia, Lunge has rendered his method altogether exact. My attention having been drawn to this fact by Professor Lunge, I have recently employed his method as well as my own with perfectly certain success. The pyrites mentioned in my previous paper, analysed by Lunge's improved method, yielded:—

	Lunge's Method.	Jannasch's Method.
	Per Cent.	Per Cent.
S	52·56	52·63
Fe	45·88	45·79
SiO ₂ &c.	1·03	1·10
	99·47	99·52

"Since Lunge's method of assaying pyrites is in general use for technical purposes, and consequently of great practical importance, it may be interesting to know that its results are completely concordant with those obtained by an altogether different method."

In a paper published in the *Zeits. f. angew. Chem.* 1889, 473, I have described in detail a number of experiments by which two of my students, Messrs. Barbezat and Obregia, working independently of one another, have investigated a special point in connexion with my improved process, namely, the question whether, as stated by me in my paper of 1880, the precipitate of ferric hydroxide can be entirely freed from sulphuric acid or not; in the latter case my process would, of course, be faulty. They found that if the precipitation of ferric hydroxide took place in the way described in Fresenius and practised in many laboratories, that is, boiling the liquid for some considerable time till the smell of ammonia is all but gone, it is unavoidable to leave some sulphuric acid in the precipitate. If, however, the operation was carried on as described by me in 1881, and again in the "Alkali-Makers' Pocketbook," that is, adding a slight but distinct excess of ammonia, and warming gently for a few minutes, till the precipitate had well settled, and filtering at once, the precipitate proved to be entirely devoid of sulphuric acid, and the results of testing agreed perfectly, both with one another, and with tests made by Fresenius' dry method. This is shown by the following table, which includes a number of assays of the same sample of pyrites according to my old method, that is, precipitating the barium sulphate without previous removal of the iron.

	Fresenius' Method.	Lunge's Improved Method.	Lunge's Old Method.
	52·46	52·70	52·38
	52·49	52·41	52·38
	52·31	52·22	51·94
..	52·26
..	52·39
Average	52·42	52·40	52·23

From this it can be seen that even my "old" method yields results no more remote from the real percentage than I had found myself in 1880, viz., 0.18 too low. For ordinary purposes the "old" method would seem to suffice. The reason why I and my students obtained with it results so near the true ones is probably this, that we ignited our precipitates in the ordinary way with a Bunsen burner and not excessively long, whilst Jannasch and Richards continued the ignition for a long time and as intensely as possible, thus decomposing a larger proportion of the barium-ferric sulphate contained in the precipitate.

Just because there is some uncertainty attached to this point, and various observers will necessarily get somewhat discordant results with my "old" method, I must strongly recommend the use of the "improved" method whenever important interests are at stake, and especially always when the analyst has to decide upon the value of a parcel bought and sold. I must do this all the more as the loss of time by the improved method need not exceed an hour at most if my further prescriptions are observed, and, as I deem these very useful for the precipitation of alumina as well as for that of ferric hydroxide in all cases, I will briefly point them out here:—

"To the liquid containing iron or alumina add a sufficient quantity of ammonia, free from carbonate, to leave a distinct smell, but avoid an unduly large excess. Warm up, if the liquid has not been hot to begin with, and allow to stand for a few minutes, till the precipitate has fairly settled. Pour off the clear liquid through a filter, and wash the precipitate on to the filter. When the liquid has drained off, wash with boiling hot water, taking care every time to churn up the whole contents of the filter into a paste by directing the jet of water in a suitable manner. Repeat this four or five times, and ascertain in the usual way whether the washing is complete. Provided the filtering paper is of good quality, the filter is lying smoothly against the glass, the funnel tube is always full and the water is boiling hot, the whole operation lasts from one-half to at most a whole hour, and the total bulk of filtrate and washings from decomposing 1 gram of pyrites does not exceed 200 to at most 250 cc., so that no evaporation is needed before precipitating the barium sulphate."

Experiments made quite recently in my laboratory by Mr. Rey have shown that by this *modus operandi* the necessity of igniting the alumina for a long time before the blow-pipe, as prescribed in the text-books, is entirely avoided. This necessity arises in the ordinary method by the fact that the alumina, just as the ferric hydrate, retains some basic sulphate which must be decomposed by prolonged and intense ignition; but when acting upon my instructions, no basic sulphate is retained. It might be supposed that on the contrary some alumina or iron would be dissolved by the excess of ammonia; but apart from the fact that this excess is very slight, it has been pointed out by Fresenius and by Blum, and has been confirmed by Mr. Rey, that in the presence of ammonium chloride no such solution of alumina or ferric oxide takes place.

Glasgow and Scottish Section.

SESSION 1890.

Jan. 7th:—

Mr. E. Rodger. "The Salt Mines at Khewra, Punjab."

Mr. T. L. Patterson. "On the Quantitative Estimation of Colouring Matters by means of their Absorption Spectra."

Mr. C. A. Fawsitt. "On the Fixation of Nitrogen."

The Meeting will take place in the Societies Rooms, 207 Bath St., Glasgow, at 8 p.m.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held on Monday, 3rd December, in the Rooms of the Philosophical Institution, Queen Street, Edinburgh.

PROFESSOR CRUM BROWN, D.S.C., F.R.S., IN THE CHAIR.

A CONVENIENT SOLUTION FOR USE IN TITRATING WELDON MUDS FOR MANGANESE PEROXIDE.

BY W. G. M'KELLAR.

A COMMON factor in connexion with the above titration quoted by Bayley and Lomas is:—"When using one cubic inch of the mud for the test, divide the number of grains of protosulphate of iron ($\text{FeSO}_4 + 7 \text{H}_2\text{O}$) oxidised by the MnO_2 by 25.88, the resulting quotient gives the manganese peroxide in lb. per cubic foot."

This factor is merely the reciprocal of the following formula, which is the result worked out from first principles:—

$$\frac{\text{MnO}_2}{2 (\text{FeSO}_4 + 7 \text{H}_2\text{O})} \times 1728 = \frac{87 \times 1728}{556 \times 1} = 0.03862.$$

7,000 7,000

That is to say, 1 grain of protosulphate of iron is equal to 0.03862 lb. of manganese peroxide, when 1 cubic inch has been used for the test.

If, therefore, when titrating mud with a standard iron solution, we make up $1.035 \cdot 2 = (25.88 \times 4 \times 10)$ grains of ferrous sulphate to 10,000 grains of a mixture of 5 parts water and 1 part strong sulphuric acid, each division of this solution will be equal to 0.04 lb. of manganese peroxide per cubic foot, if 1 cubic inch has been under examination. We thus have a solution which reads directly from the burette without the use of a table. Thus,—

50 Div. = 2.00 lb. MnO_2 per cubic foot.

53.25 Div. = 2.13 lb. MnO_2 per cubic foot,

As a perfectly pure iron salt cannot be obtained conveniently, it is advisable in actual practice to make the bichrome standard, which may be got by making up 183.06 grains of bichromate of potash to 10,000 grains fluid. One division of this solution is equal to 0.2085 grains iron.

(0.2588×4) grains iron protosulphate = 1.0352 grs.
 $(\text{FeSO}_4 + 7 \text{H}_2\text{O}) = 0.040 \text{ lb. manganese peroxide per cubic foot.}$

And for the iron solution, using about 1,050 grains of ferrous sulphate per 10,000 fluid grains acidified water, titrating, and then diluting down the iron solution with water till it is equal to the bichrome.

In practice, as the iron solution oxidises, it is advisable to make the solution 0.25 division over strength in 50 divisions, because the strength alters in three weeks' time, about one division per 100. This excess in strength in a mud running from 2.00 to 2.50 lb. MnO_2 per cubic foot would limit the probable error due to the variation of the solution to 0.01 lb., first of all negatively, then, as the solution aged, positively.

The usual method of titration is employed, viz., running in the iron solution till all the mud has dissolved, which requires an excess of from 3 to 5 divisions iron solution; then titrating back with bichrome, deducting the bichrome divisions from the iron divisions and multiplying remainder by 0.04.

The equivalent quantity in grammes, viz., 11.862 grms. bichromate of potash and about 69.4 grms. ferrous sulphate crystal, each made up to 1 litre, would serve the purpose equally well. 1 cc. = 0.04 lb. MnO_2 per cubic foot when using 1 cubic inch of the mud.

DISCUSSION.

The CHAIRMAN pointed out that, quite apart from the chemical bearing of the paper, Mr. McKellar's work showed how much chemists were hampered by the monstrous system of weights and measures in use for commercial purposes in this country. He hoped to live to see the French system adopted generally. We need have no false pride in the matter. We could quite well afford to adopt this, perhaps the most valuable result of the French Revolution, and we could adopt it without any serious revolution in anything else.

Mr. D. B. DOTT said he entirely agreed with what had been said regarding this question of weights and measures. If such a system as the French were adopted it would be much easier for all concerned. It was not generally known that pharmaceutical men had a special difficulty with the present system. By the abolition of the old troy ounce of 480 grains, and hence the compulsory use of the avoirdupois ounce of $437\frac{1}{2}$ grains, they had innumerable calculations which were most inconvenient. The grain never could have been a part of the avoirdupois system. The avoirdupois pound certainly contained 7,000 grains, still the grain was a troy and not an avoirdupois denomination. Confusion had been caused by mixing two different systems.

that the Society's meetings would be of great service to young chemists, but unless the Society took some steps whereby those who were desirous of pursuing technical chemical work might obtain the requisite knowledge and practice, the benefit of the meetings alone to young chemists would be *nil*. He did not profess to be able to formulate a plan, but had mentioned the matter in the hope that discussion would follow, as no doubt many others members of the Society were fully alive to the want. Their excellently conducted Journal, notwithstanding its value both for study and for reference, did not cover the field which the sectional meetings were intended to occupy.

Mr. BOY said that the difficulty to which Mr. Irvine had referred was one which affected nearly all societies of a similar nature. Both the London and Edinburgh Sections of the Pharmaceutical Society had very great difficulty in getting papers, although they met only once a month. This Society had established at their head-quarters in London a research laboratory, whence came the majority of the contributions which were given at the evening meetings last session. To this laboratory students who were sufficiently advanced were admitted, and were allowed to work free of charge, although they were not paid anything. This Section of the Society of Chemical Industry should have no difficulty in securing sufficient papers for their three meetings in Edinburgh during the session.

Mr. DOTT agreed so far with what had been said, but thought the tendency was rather to increase than diminish scientific communications. Apart from secret processes which it was not desirable to publish, there were many chemically interesting facts elicited in the laboratory. One thing he felt strongly upon, there should be no "beating" for papers; rather let there be fewer meetings and the papers be of a higher quality.

The CHAIRMAN said that there were difficulties, which no doubt Mr. Irvine saw, in the way of carrying out his ideas. Scientific interests and trade interests would always tend to clash. Young men must work somewhere if they were to obtain practical results, and even if they themselves had no trade interests their employers were in a different position. Something might be done in laboratories of universities and other schools where chemistry was studied, where it was to be hoped that there were no interests to prevent full publicity. They welcomed discussions as to how the usefulness of the Society and of that Section could be increased; but whether that increase of usefulness came about in the way suggested or otherwise, the thanks of the Society would be due to Mr. Irvine for calling attention to the subject.

Communication.

DISCUSSION ON THE WORK OF THE SECTIONS.

Mr. ROBERT IRVINE referred to a letter which he had received from Mr. Henderson as to the great difficulty of getting original papers for the various meetings of the Section. He had pointed out in reply that it was absurd to expect chemical manufacturers to publish their main processes before the Society. This applied not only to manufacturers, but also to technical chemists employed by them, who were naturally, as a rule, bound down not to divulge the information committed to them. He had hoped

NOTE ON THE BEHAVIOUR OF CERTAIN EXPLOSIVES UNDER PERCUSSION.

BY A. WERNER CROSQVIST, STOCKHOLM.

IN order to ascertain the degree of sensitiveness to concussion of certain explosives in use in Sweden, I have made some experiments on samples of from 0.15 to 0.70 gm. The samples, at a temperature varying between 15 to 22 °C., were placed between steel faces which were then struck by the falling weight, and the following figures in kilogram-

meters and foot pounds give the minimum impact which resulted in explosion:—

	Kilogram-meters.	Foot Pounds.
Nitro-glycerin, fluid.....	0.41	2.8
„ frozen.....	0.80	5.6
„ partially frozen.....	0.27	1.9

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in or relating to Apparatus for Evaporating Water, and Heating Feed-Water. E. Paul, Liverpool. Eng. Pat. 14,931, October 17, 1888. 8d.

THE apparatus described in the specification is used for the purpose of evaporating liquids or for heating feed-water, by means of two concentric vessels, the inner one being much shorter than the outer one. The space between forms the steam chamber, the other containing the liquid for evaporation which also circulates through the former by means of tubes. The invention principally deals with the arrangement of and the method of fixing the circulating tubes, and with the automatic regulation of the water supply, for details of which the drawings of the specification should be consulted. There are five claims.—B.

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	3d.
Above 8d., and not exceeding 1s. 6d.	1d.
„ 1s. 6d., „ „ 2s. 4d.	1½d.
„ 2s. 4d., „ „ 3s. 4d.	2d.

Improvements in Apparatus for Calcining, Drying, Roasting or Carbonising Substances or Materials, and Extracting Gases, Spirits, or Acids, or other Products therefrom. R. Cunliffe, Pendleton. Eng. Pat. 15,460, October 27, 1888. 8d.

THE improvements relate to the apparatus described in Eng. Pats. 14,141 of 1886, and 10,723 of 1887 (this Journal, 1887, 814), and consists in arrangements for heating the vessel or retort in which the material is placed. The retort is partially enclosed in a casing, formed of metal plates, between which is a cavity filled with asbestos or other non-conductor of heat. The casing which surrounds the trunnion is also covered with the same material. The retort is heated by a furnace mounted in a frame with wheels which run on rails so that it can be readily withdrawn. A further improvement consists in supplying air to the furnace by a fan, the air from which being conveyed through pipes or cavities around the furnace becomes heated, and then passing through the retort assists in drying the materials—the process being thus effected more thoroughly, with greater rapidity and with a comparatively small quantity of fuel. The valuable volatile products can be collected and condensed in any suitable manner; or if deleterious may be passed through the furnace and consumed.—E. S.

Improvements in Machines for Drying Granular, Fibrous, and like Materials, also Appliances for Cleaning, Bleaching, Damping, Germinating, and Disinfecting. R. Howarth, Rochdale. Eng. Pat. 15,731, November 1, 1888. 8d.

IN one arrangement of this apparatus, as employed for drying granular substances, a rotary horizontal cylinder with perforated circumference is placed within a fixed casing. The cylinder is mounted on a central perforated tubular shaft carried in bearings, the ends of the tube being put in connexion with an exhaust fan. The cylinder is filled with the granular substance to such a height as to entirely cover the perforated central tube in order that the current of air produced by the action of the exhaust fan may pass through the permeous mass before reaching the exhaust channels. There are various valves, shutters, and devices for the proper regulation of the air and for the passage of the drying substances.

In another arrangement, instead of rotary cylinders, inclined stationary channels are used, having perforated walls within a surrounding casing, down which channels the materials pass at regulated speed whilst subjected to the action of the exhaust fans as in the foregoing arrangement. There are two sheets of drawings and eight claims.—B.

Improvements in Apparatus for the Distillation and Liquefaction of Condensable Gases as applied to Refrigerating Apparatus. H. Puplett and J. L. Rigg, London. Eng. Pat. 16,372, November 12, 1888. 8d.

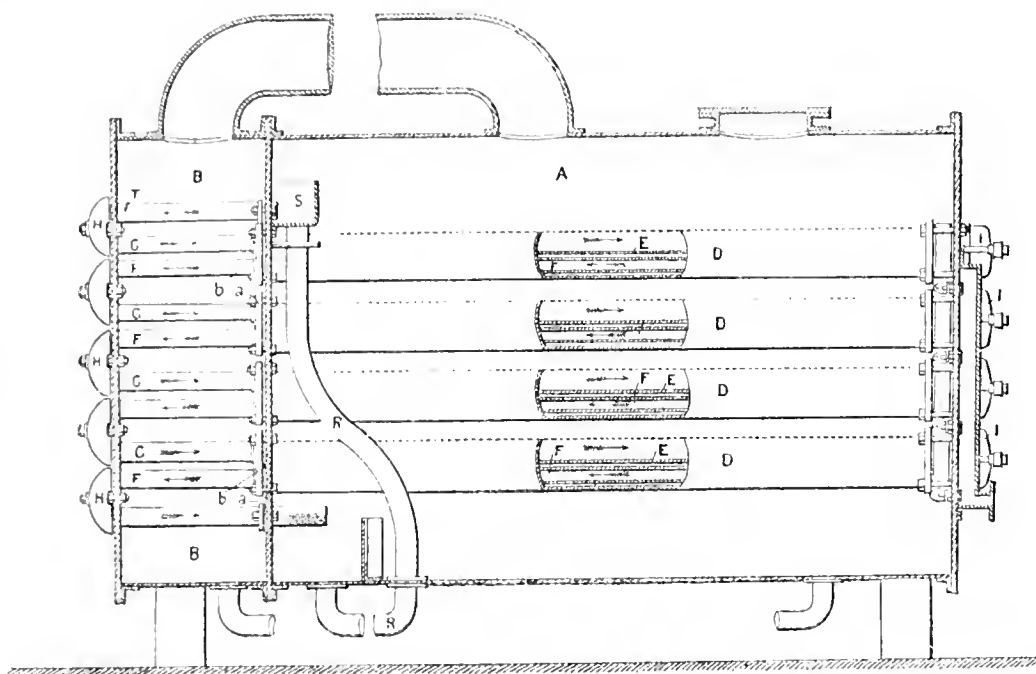

THE improvements consist in arrangements for rendering automatic the evaporation, liquefaction, and circulation of the condensable gases in refrigerating apparatus. The patentees state that hitherto the liquid from the absorber has been returned to the generator by means of pumps, and to avoid the use of these they provide a discharge valve at the lowest point of the absorber, the valve being operated by means of a rocking beam carrying an adjustable balance box at each end. These boxes are governed by a double tumbling basin supplied with a regulated stream of water from any source, and, according as the discharge takes place at either end, the valve is opened or closed, when open allowing the accumulated liquid to gravitate to the generator. Two sheets of diagrams accompany the specification.—B.

Improvements in Apparatus for Evaporating Liquids. T. Slater, London. Eng. Pat. 34, January 1, 1889. 11d.

THE object of this invention is to afford means for the easy repair and renewal of tubular gutters, trays, and similar heating surfaces, in apparatus in which evaporation is carried

on under a vacuum. For this purpose a series of circular tubes D in the accompanying sketch pass through a vacuum chamber A, and are secured in opposite tube plates by means of packing rings *a* and suitable tighteners.

The upper part of the tubes—dotted line in figure—within the vacuum chamber is cut away or left open, and a longitudinal division or tray E inserted and secured steam-tight to the sides of the tube, about midway down. From

one end of the upper half of the double tube so formed a smaller tube G is taken out, passing through the steam chamber B which adjoins the vacuum chamber on that side; and the liquid for concentration enters the system through the tube G from the passages R and S. The lower half of the double tube is traversed by another small return tube F, secured steam-tight into the opposite end of the lower part of the larger tube, and passing freely through the other end and through the steam chamber. This tube, with the assistance of the caps H and I, and the succeeding pipe G, serves as a conduit for the surplus liquid from the evaporating gutter to the next lower one. The steam from the chamber, entering the annular space between tube F and the lower half of tube D evaporates the liquid on the gutter E, whilst at the same time continuing to heat the liquid overflowing to the next gutter. All the pipes can be separately withdrawn and re-inserted, and the system can be extended to multiple-effect apparatus. Three claims are recorded, and three drawings accompany the specification.—B.

A Fluid for Removing and Preventing Incrustation in Steam Boilers. R. Cosslett, Bath. Eng. Pat. 148, January 4, 1889. 4d.

THE fluid is composed of a mixture of a mineral illuminating oil and a mineral lubricating oil, those extracted from coal and shale being best for the purpose. The two oils are mixed together and added gradually to the water in the boiler. The best proportion for use is stated to be half a pint per week of six days for each 10-horse power boiler; double the above, if worked day and night. Foul boilers require an additional quantity until they are clean. In new and clean boilers incrustation is prevented, and where it has been formed, "the oils not having an affinity for the incrustation percolate through the same, and on coming in contact with the heated boiler plates are expanded, thus forcing off the incrustation."—E. S.

Improvements in Means or Apparatus for Removing Impurities from Water in Steam Boilers. R. W. E. Sanderson, Manchester. From J. O'Brien and S. J. Weaver, St. Louis, U.S.A. Eng. Pat. 381, January 9, 1889. 6d.

THE invention relates to improvements in a feed-water purifier and heater for steam boilers described in Eng. Pat. 4342 of 1888, and consists in combining therewith apparatus for removing some or all of the impurities which pass through the purifier and enter the boiler with the feed-water. A circulating pipe enters the boiler at or about water level, and extends inward, terminating, preferably, below the feed-water purifier about water level and over a pipe connected to a mud-drum. Outside the boiler the circulating pipe is provided with valves and taps, and is by preference connected to the mud-drum, which has a valve and blow-off cock. The valves being open, the feed-water circulates from the upper to the lower part of the boiler, and deposits the impurities at the bottom of the drum, from which they may be expelled by closing the valve and opening the blow-off cock. A modification of the invention dispenses with the mud-drum, an enlarged pipe being substituted for it. There are four claims and one drawing.—E. S.

A Process of Manufacturing a New Substance for Removing Incrustation and other Sedimentary Deposits, particularly from Steam Boilers, and for Cleaning other Vessels. M. van Look, Barmen, Germany. Eng. Pat. 5791, April 4, 1889. 4d.

STARCH, to which caramel or other innocuous colouring matter has been added, is dissolved in hot water by blowing steam into the mass, when a quantity of caustic soda, about equal to the weight of the starch, is added. It is claimed that this compound will detach old incrustations as well as prevent the formation of new.—W. L. C.

Improvements in Bag Filters. B. J. B. Mills, London.
From J. Rétif, Lyons, France. Eng. Pat. 6987, April 26,
1889. 6d.

It has been customary in the employment of bag filters to fix them by screws or by tying to the under side of the reservoir or vat in which the liquid to be filtered is contained. The patentee in this specification proposes to suspend them through an opening in the bottom of the reservoir or vat, and shows several devices for making a tight joint between the filter and the vat, which is effected solely by the pressure of the head of the unfiltered liquid.—C. C. H.

An Improved Automatic Filter. J. Leslie, Belfast. Eng.
Pat. 9244, June 4, 1889. 6d.

THE filter consists of an upright vessel, made of any suitable material, fitted with an air-tight cover to withstand internal pressure. To this cover is attached a cage which projects into the filter and is enclosed in a bag securely fastened to it; the bag is coated, preferably on the outside, with a suitable filtering medium. The liquid is admitted under pressure from the supply at the bottom of the filter, passes upwards through a perforated plate at the bottom, and through the filtering bag, and is discharged from a pipe at the top.—E. S.

An Improved Anti-Incrustator for Cleansing Boilers and Pipes and such like. I. M. Coates, Wallington. Eng.
Pat. 11,195, July 11, 1889. 4d.

TWENTY-FOUR parts of common soda are mixed with 3 parts of animal charcoal, and to these are added in succession 4 parts of Fuller's earth, 12 of alum and 5 of Demerara sugar. The mixture is dissolved in water before use.

—W. L. C.

A Certain New and Useful Process for Facilitating Chemical Reactions. H. Bower, Philadelphia, U.S.A.
Eng. Pat. 13,549, August 27, 1889. 8d.

THIS invention is for mechanically facilitating chemical reactions by subjecting two or more substances to be combined to the effect of impact and attrition from opposing jets, with or without the use of a finely-divided solid agent.

For the manufacture of ammonia, hydrogen and nitrogen are mixed in the proper proportions, and as the blast is turned on, finely-divided graphite is added. The gases are then forced, under a pressure of 200 lb. to the inch, through heating coils, and discharged into a vessel in opposing jets, ammonia being formed. The gas is then led into a dust chamber, for deposition of graphite, and finally into an absorber.

The apparatus may be used for two liquids, or a solid and a gas, &c., e.g., steam and sodium chloride, for production of hydrochloric acid; solution of sulphate of soda and milk of caustic lime to form caustic soda; water and neutral fats to produce fatty acids and glycerin; and for the action of carbon, hydrogen, or other reducing agents upon metallic oxides, such as alumina, producing aluminium by the gradual reduction of the oxide. Several other applications are suggested.

—D. A. S.

II.—FUEL, GAS, AND LIGHT.

Studies of Coal Gas. E. St. Claire-Deville. Journ. des
Usines à Gaz, 1889, 13.

AT the experimental gasworks at La Villette over 1,000 experiments have been carried on from 1872—84, with 59 kinds of coal. Each experiment lasted three days, and was made with 36 tons of coal. It was found that the estimation of the benzene by different methods gave very varying results. The author shows that benzene, in many cases, is absorbed by the water in the water joints, and also lost during the determination of carbonic acid by means of a solution of soda, and thus escapes estimation. Water which has been saturated with gas, such as the water from meters, and the reservoirs of gas-holders, yielded, when carefully distilled, 350—400 grms. of benzene per cubic metre, corresponding to about 100 litres of benzene vapour. In consequence of this, the amount of carbonic acid found is always too high by about 1 per cent. From 1883 the carbonic acid has always been estimated gravimetrically, the total amount of heavy hydrocarbons estimated by means of bromine. The benzene was obtained by cooling the gases to -22°C ., the dry gas being passed through two worms, cooled by means of ice and salt, at the rate of about 250 litres per hour. In the first tube most of the products of condensation separate, and in the second, nothing, or only very little. These consist mainly of benzene. From the gases produced from five kinds of cannel coal were obtained 27.7—48.6 grms. of condensation products per cubic metre. In addition to this, there is the benzene vapour which is not liquefied at -22° . The calculated amount is 23.5 grms. per cubic metre. This missing quantity can be obtained by cooling with methyl chloride to -70° to -75°C . This weight, 23.5 grms., is constant for all kinds of gas from bituminous coal—sufficiently constant for all practical purposes. Gas from the gasworks at La Villette yielded, in nine determinations, 36.9—41.8 grms. of products liquid at -70° , of which 22.3 to 23.5 grms. condensed between -22° and -70° .

Cannel coals behave differently, as from them more is deposited at -70° , namely 27.9 grms. There are doubtless here deposited hydrocarbons which do not belong to the benzene series. The various products from the gas at La Villette condensed at -22° , yielded, when submitted to fractional distillation:—between 80° and 90° , 54.5 per cent.; 90° — 115° , 26 per cent.; 115° — 160° , 17.5 per cent.; loss, 2 per cent. The other products liquid at -70° , yielded:— 80° — 90° , 91.76 per cent.; residue, 7.93 per cent.; loss, 0.31 per cent. The total products of condensation were composed of benzene (boiling at 81°C .), 76.39 per cent.; toluene (boiling at 111°C .), 10.74 per cent.; xylene and higher products (boiling points from 139° upwards), 7.22 per cent.; residue in still, 4.66 per cent.; loss, 0.99 per cent. The liquid products contained practically 75 per cent. of benzene.

Paris illuminating gas contained, on an average:—heavy hydrocarbons absorbed by bromine, 5.05 per cent. by volume, of which the aromatic hydrocarbons amounted to 0.95 per cent., and the others to 4.10 per cent. by volume.

The aromatic hydrocarbons were present in this case to the amount of 35.48 grms. per cubic metre (1 litre of benzene vapour = 3.73 grms.). Great variations did not occur in the Paris gas, and the amount of benzene was always very close to 1 per cent. by volume.

Examination of the Coals.—The author divides gas-coals, according to the percentage of oxygen they contain, into five groups, viz., containing from 5—6.5, 6.5 to 7.5, 7.5 to 9, 9—11, and 11—13 per cent. respectively. The varying amounts of oxygen in the different kinds of coal is of considerable influence on the details of the gas-making processes (Bunte, Journ. f. Gasbeleuchtung, 1886, 709), namely, with regard to the formation of carbonic acid, carbonic oxide, heavy hydrocarbons, tar, gas-liquor and also the yield of gas.

The following tables show the composition of the coals, and the effects of increasing proportions of oxygen in them on the manufacture of the gas:—

Class of Coal.	I.	II.	III.	IV.	V.
Oxygen in the coal, not including water or ash	Per Cent. 5.36	Per Cent. 6.66	Per Cent. 7.71	Per Cent. 10.10	Per Cent. 11.79
Oxygen and nitrogen in the raw coal.....	5.83	6.91	7.80	9.71	10.55
Carbon in the raw coal.....	78.47	78.18	76.85	72.93	67.86
Carbon in the coal, not including water or ash	88.79	90.24	89.48	87.48	83.10
Hygroscopic moisture in the raw coal.....	2.17	2.70	3.31	4.34	6.17
Volatile products yielded by the raw coal.....	26.82	31.59	33.80	37.34	39.27
100 kilos. of coal yield.....cubic metres of gas.....	30.13	31.01	30.64	29.72	27.44
" " ".....kilos. of coke.....	71.5	67.6	64.9	60.9	57.8
" " ".....kilos. of tar.....	3.902	4.652	5.079	5.478	5.592
" " ".....kilos. of gas liquor.....	4.584	5.537	6.805	8.616	9.861
Number of litres of gas used for 1 "candle" of illuminating power.....	132.1	111.7	103.8	102.1	101.8
Number of "candles" per 100 kilos. of coal.....	227	278	295	291	269

Also the analysis of the gas shows that it varies according to the amount of oxygen in the coal. As the oxygen increases these results are:—

<i>An increase in—</i>	Per Cent.
Volatile constituents of the coal of ..	26—40
Specific gravity of the gas.....	0.35—0.49
Illuminating power	132—101 (litres per 1 candle).
Carbonic acid.....	Per Cent. 1.40—3.13
Carbonic oxide.....	6.50—0.12
Methane.....	34—37
Heavy hydrocarbons of the fatty series	2.50—4.80
Tar.....	3.09—5.06
Gas liquor.....	4.05—0.10

A decrease in—

Hydrogen	55—42
Coke.....	71.5—57.8
Temperature, obtained by burning the coke in the retort furnaces = 1,330°—1,220°.	

St. Claire-Deville also investigated the other heavy hydrocarbons not belonging to the aromatic series, and found ethylene, propylene and acetylene—the first of these in large quantities. He also examined the illuminating constituents of the gas, and found that, of the total illuminating power of the gas, the heavy hydrocarbons of the fatty series produced 34.2 per cent.; the aromatic hydrocarbons containing 52 per cent. of benzene (down to -22°) 15.9 per cent.; while the aromatic hydrocarbons containing 92 per cent. of benzene (-22°—70°) produced 49.2 per cent.

In the experiments to test the influence of the temperature of distillation upon the formation of aromatic hydrocarbons in gas, it was found that the amount of these increased considerably as the heat rose from dull red to bright red, whilst those of the fatty series did not vary appreciably. Consequently gas obtained at the higher temperature is richer in pure benzene than that obtained at the lower temperature. The investigation into the amount of the hydrocarbons of the aromatic and of the fatty series in the gas showed that in the different stages of the distillation the former rose steadily from the beginning, attained its maximum amount in the second hour, and then sank slowly, whereas the latter was high during the first hour and then fell rapidly till the fourth hour.—E. E. B.

PATENTS.

Improvements in Mantles for Incandescent Lighting and Heating. R. D. Bowman, London. Eng. Pat. 17,866, December 6, 1888. 6d.

FIBROUS material is saturated with "a strong solution of the soluble salts of refractory materials such as the chlorides or

sulphates of calcium, zirconium, magnesium," &c. This material is wound round a parallel mandril and afterwards coated with the oxides of the above metals. On withdrawal of the mandril it may be replaced "by a core of whiting and saturated solution of magnesium sulphate or chloride." —D. A. S.

Improvements in the Purification of Gases. E. Solvay, Brussels, Belgium. Eng. Pat. 18,573, December 19, 1888. 8d.

This is a device for filtering gases from suspended dust or vapour in the vesicular state. The gases are caused to pass through a layer of sand or suitable granular or fibrous substance.—D. A. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

A Methyl-furfural and the Corresponding Methyl-pyromucic Acid. H. B. Heill. Ber. 22, 607—608.

ABOUT 12 years ago the author drew attention to the large quantity of furfural (furfural) that is produced by distilling wood at a low temperature (Ber. 10, 936). A fractionation was effected by the use of Hempel's head-tube, so that constant boiling oils were obtained. After repeated fractionation there was obtained in the portion distilling below 205°, besides one boiling at 160°—165°,—that containing the furfural, viz., the fraction boiling at 180°—185°, and also a smaller portion boiling at 185°—190°, whilst those fractions boiling respectively at 165°—180° and 190°—205° became continually smaller on redistillation. After continued fractionation at length a fraction boiling at 184°—186° was obtained, and this chiefly composed the fraction which distilled between 180°—190°. The oil thus obtained gave a marked aldehyde reaction with magenta-sulphurous acid, reduced silver oxide easily on warming, and gave, with sodium bisulphite, a beautiful crystalline compound. The aldehyde recovered from the bisulphite compound boiled constantly at 186.5°—187° (mercurial column in the vapour) under pressure of 756 mm. Since these properties left little doubt that the compound was a methyl-furfural, it was converted into the corresponding acid. This proved to be very similar to pyromucic acid, but it melted at 108°—109°, and dissolved with more ease in water than that acid, also with more ease in benzene and in chloroform. It proved to be methyl-pyromucic acid, and consequently the mother substance was undoubtedly methyl-furfural. The oil boiling at 186.5°—187° proved to be soluble in

30 parts of cold water, and the aqueous solution yielded with ammonia a beautifully crystalline compound melting at $86-87^{\circ}$. With phenylhydrazine methyl-furfural gives a liquid hydrazone, and yields with resorcinol and hydrochloric acid an orange-red, whilst with pyrogallol and hydrochloric acid, a carmine-red condensation product. Acetate of aniline paper is only coloured yellow by its aqueous solution, but later on a deep orange-red colour is developed. The author is examining the methyl-pyroneic acid with a view to elucidating the structure of the methyl-furfural.

On Fucosol. Maquenne. *Compt. Rend.* **109**, 571—573.

THIS product, which is obtained by distilling certain *algæ* with dilute sulphuric acid, was described by Stenhouse (*Proc. Roy. Soc.* **20**, 80) as isomeric with furfural (furfural). The author has prepared this substance from *Fucus vesiculosus*, obtaining about 1 per cent. on the dried *algæ*, and finds that by careful rectification it may be separated into two portions, one boiling at $162^{\circ}-163^{\circ}$, forming about nine-tenths of the whole, and the other, the remaining tenth, boiling at $185^{\circ}-187^{\circ}$.

The former of these is found to be identical with furfural, and the latter to be methyl-furfural, agreeing in all its properties with methyl-furfural as obtained by Heill (*Ber.* **22**, 607, see previous abstract) from wood tar.—A. L. S.

On Formation of Higher Aromatic Hydrocarbons. E. von Boyen. *Chem. Zeit.* **13**, 905.

THE author (this *Journal*, 1889, 273) showed the formation of picene in the distillation of residual paraffin. This, however, is probably derived from hydrocarbons contained therein of high specific gravity and high boiling point.

The author recently observed the formation of picene during the distillation of the last distillate of neutral tar oils containing no paraffin. The distillate freed from creosote by means of alkali and distilled with superheated steam, yielded a viscous oil boiling over 360° , sp. gr. 0.935, of a clear yellow colour which soon darkened. In a few days abundance of yellow granular picene separated; a clear viscous lubricating oil was obtained by refining with acid and alkali.

This oil, containing the true picene former, was treated as in Kellé's process for obtaining retene by heating with 5 per cent. of sulphur (at $200^{\circ}-250^{\circ}$), a strong evolution of sulphuretted hydrogen taking place. The product gave on distillation a viscous, dark-coloured oil of disagreeable odour; in 24 hours picene crystals separated. Thus picene is formed from per- or polyhydrides contained in the neutral tar oils of highest gravity and boiling point by oxidation (either with sulphur or oxygen of the air) at the boiling temperature.

Hard and soft paraffin carefully freed from every trace of oil no longer gave the smallest trace of picene on distilling.

—D. A. S.

Paraffins in Coal-Tar Oils. W. W. Staveley. *Chem. Zeit.* **13**, 1108.

AFTER the distillation of coal tar in large tar stills is complete, and no more heavy anthracene oils flow from the condensers, the author has observed that a small quantity of water together with an oil, lighter than water, drops from the condenser. By the distillation of 20 tons of coal tar several gallons of this oil were obtained. The water accompanying it was blood-red and contained sulphocyanides. The oil when submitted to fractional distillation in Le Bel's apparatus yielded oils distilling at the following temperatures, and having the following specific gravities:—

Boiling Point.	Specific Gravity at 15° C.
$50^{\circ}-55$	0.802
$55-75$	0.815
$75-80$	0.834
$80-81$	0.843

In some tar works during the distillation, injurious fumes are given off which are passed through water contained in receivers and then burnt. In these receivers the author has found large crystals of sulphur and also collected light oils, which when treated with fuming sulphuric acid and subjected to fractional distillation, yielded:—

—	Specific Gravity at 15° .	Boiling Point.
cc.		$^{\circ}$
43	0.763	$55-75$
40	0.732	$75-85$
35	0.726	$85-92$
40	0.725	$92-107$
35	0.731	$107-143$
193		

The author believes that these light oils are present in all portions of the distillate from coal tar, and even from pitch. He considers that they are formed by the dissociation of the vapours during distillation. From anthracene oil (sp. gr. 1.060 and 1.140) the author obtained by fractional distillation—

1.20 per cent. by volume of water containing sulphocyanides.

0.33 per cent. of 40—90 benzene (sp. gr. = 0.874).

0.60 per cent. of 90—160 solvent naphtha.

0.70 per cent. of naphtha (sp. gr. = 0.935).—E. E. B.

On c-Methylpyrrolines. M. Dénstedt and A. Lehne. *Ber.* **22**, 1918—1920. (Compare *Ber.* **19**, 2199; *J. Chem. Soc.* 1886, 1043; and *Ber.* **21**, 3439; *J. Chem. Soc.* 1889, 400.)

CIAMICIAN and Silber (*Ber.* **19**, 1408; *J. Chem. Soc.* 1886, 719) describe the action of acetic anhydride on *c*-methylpyrroline boiling at $140^{\circ}-153^{\circ}$. Their results are usually in unison with those of the authors, but in this case the authors find two isomeric *c*-methylpyrrolines, one boiling $142^{\circ}-143^{\circ}$, the other $147^{\circ}-148^{\circ}$.

For this research these were prepared pure by boiling the corresponding animal oil pyrroline fraction $140^{\circ}-153^{\circ}$ with caustic potash and extracting with ether. This was repeated and the resulting oil fractionated carefully into the fractions $142^{\circ}-143^{\circ}$ and $147^{\circ}-148^{\circ}$.

The best method of identifying homologous pyrrolines is by condensation of benzaldehyde with the *c*-acetylpyrrolines to pyrroleimnamyl ketones.

The very crystallisable nature of these compounds and their greater solubility in warm than in cold alcohol enables them to be easily obtained in the pure state.

Both isomeric *c*-methyl pyrrolines were thus treated, one part being heated in a closed tube with two to three parts of acetic anhydride and one part of sodium acetate for three to four hours at 190° ; the product taken up with warm water and subjected to a sharp current of steam. The resinous mass is mixed with animal charcoal and dilute alcohol, boiled with water, the cooled filtrate shaken several times with ether, and the ether residue distilled. Water and acetic acid come over first, and the thermometer thereafter rises rapidly to the constant boiling point of the particular acetyl compound. If it solidifies, separate the crystals and purify the crystals obtained by means of water and dilute alcohol or by redistillation.

Thus the product (if the simultaneously formed *c*-acetyl-*c*-methyl pyrroline be disregarded) is *c*-acetyl-*c*-methyl pyrroline boiling at 240° and melting $85^{\circ}-86^{\circ}$ theoretically as from $147^{\circ}-148^{\circ}$ *a*-methylpyrroline. The research was undertaken solely in hope of getting the same compound. For further identification this was boiled with benzaldehyde and very dilute caustic potash. The condensation succeeded very easily, and a yellow crystalline mass separated in a few minutes from the boiling liquid, the melting point being 193° , and when recrystallised from boiling alcohol this was

confirmed. It precipitated on cooling as sulphur-yellow firm needles. Analysis gave $C_{11}H_{13}NO$ *α*-methylpyrrylcinnamyl ketone, or—

On treating 142'-143 β -methylpyrroline as above, the chief product is an oil boiling at 230°-235°, solidifying in a freezing mixture but liquefying at 25°. By condensation with benzaldehyde the product crystallised in clear yellow plates melting at 156-157°, giving on analysis $C_{11}H_{13}NO$ as above.

Thus it will be seen that the dimethylindole produced (Ber. **21**, 3440) is manifestly not a pure product.—D. A. S.

On *c*-Dimethylpyrrolines. M. Demstedt. Ber. 22, 1920—1924.

ALTHOUGH theoretically there should be four α -dimethylpyrrolines, only two have been known till now, namely the α - α' -dimethylpyrroline of Kuorr (Ber. **18**, 1158) and of Paul (Ber. **18**, 2254; this Journal, 1885, 739), and secondly, the α - β' -dimethylpyrroline of Kuorr (Ann. Chem. Pharm. **236**, 317).

Claunician and Weidel (Ber. **13**, 78; J. Chem. Soc. 1880, 403) isolated a *c*-dimethylpyrroline from Dippel's oil identical with the first of those mentioned above, the boiling points and reactions being the same.

The author (Ber. **21**, 3429) showed that from *n*-isopropylpyrroline both *c*-methylpyrrolines could be obtained. To confirm the view that the α and β (α' and β' hydrogen) in the respective pyrrolines is not replaced by an alkyl group, the following research was undertaken:—

From α - β -dimethylpyrroline the condensation product α - β' -dimethylpyrrolylcinnamyl ketone was obtained in yellow shining plates, giving on analysis $C_{13}H_{15}NO$. Its constitution is—

On passing dry hydrochloric acid gas into an ethereal solution of the α - β' -dimethylpyrroline obtained by Knorr's method, needle-shaped crystals were obtained and a brown liquid. The latter was solidified, the ether decanted, and the residue on solution in water gave yellow flocculent precipitates, with platinum chloride and picric acid, both of which were unstable. The salt is a double one of di- or trimethylpyrroline. This compound is also unstable if set free from hydrochloric acid solution by alkali. On distilling with steam it is partly reconverted to α - β' -methylpyrroline, and only near the close of the distillation it distils more slowly, giving yellowish crystalline plates, melting at 45° — 50° , soluble in hydrochloric acid and giving the above reactions. The greater part of the base remains behind in the flask as a dark yellow resinous mass, soluble in ether, but on evaporation of the ether, it is not volatile, and chars on heating. On exposure to air it deliquesces, and becomes in a few hours a dark-coloured resinous mass. Thus no indole compound can be obtained from the aqueous solution of the chloride. On allowing it to stand with dilute sulphuric acid, in two days the colour is dark red, and finally it becomes a brownish-black resinous mass. The acid liquid gives on distillation only traces of α - β' -dimethylpyrroline. Thus also no indole-like body occurs in the distilled product. The resinous mass shaken with ether gives a red amorphous substance on evaporation. This is soluble in dilute HCl. Indoles, of course, though soluble in concentrated HCl, are reprecipitated on adding water.

Dimethylpyrroline from Dippel's Oil.—The author and Zimmerman (Ber. 20, 857), by treating the dimethylpyrroline from Dippel's oil, boiling at 165°, with HCl gas in ethereal solution, obtained an indole. This salt was not completely soluble in water, but the solution, on standing with dilute sulphuric acid for a day, became a brownish-black resinous mass, while the insoluble part was unchanged. By distilling with steam, a clear yellow oil, with the characteristic odour, was obtained, and which distinctly gave all the essential indole reactions. The distillate, shaken with ether, dried with caustic alkali, distilled (on evaporation of the ether) at 283°, corresponded on analysis

to tetramethylindole, $C_{12}H_{15}N$. It dissolved in concentrated hydrochloric acid, and was reprecipitated with water. The picrate was obtained in lustrous garnet-red needles, melting at 100° . The dihydroquinoline was obtained as an oil giving the characteristic odour and reactions, becoming rosened on exposure to air, dissolving in dilute hydrochloric acid and being precipitated from concentrated hydrochloric acid by ferric chloride as the characteristic golden yellow double salt, and giving with mercuric chloride and picric acid yellow precipitates.

This conversion of the dimethylpyrroline, boiling at 165°, from Dippel's oil, renders it probable that both α - α' - and α - β' -dimethylpyrrolines are contained.

The formation of tetramethylindole from tetramethyldipyrroline is as follows :—

Showing α - β 3,4 tetramethylindole or Pr. 2,3 B. 3,4. tetramethylindole.—D. A. S.

On the c-Dimethylpyrrolines contained in Dippel's Oil.
M. Dennstedt, Ber. **22**, 1924—1929. (Compare Ber. **14**,
934; **20**, 1370; **13**, 78; **19**, 1408, 2195; J. Chem. Soc.
1880, 403; and this Journal, 1886, 236.)

In addition to the evidence evinced by the foregoing communication, the author has found another circumstance pointing to the presence of α - β -dimethylpyrroline in Dippel's oil.

On acting on pyrroline and its homologues with acetic anhydride, the acetyl group replaces easily the methine hydrogen; as a rule only two hydrogen atoms at most are replaced in this way. And Ciamician has by a series of careful and laborious experiments shown that only the carbon next the nitrogen enters with the acetyl group into the compound. On treating with acetic anhydride and sodium acetate in a sealed tube at 190°, taking up the product with warm water and distilling, an *n*-acetylpyrroline comes over. The residue in the flask is shaken with ether, and the ethereal residue distilled, the thermometer eventually rises to 250°, the entire mixture distilling at 250°—260°. The product, a yellow-coloured viscous oil, has no longer the *n*-acetylpyrroline smell, but rather that of *c*-acetylpyrroline. It cannot, however, be solidified in a freezing mixture.

The *silver salt*, $\text{AgC}_5\text{H}_{10}\text{NO}$, was prepared as a white crystalline precipitate, darkening on exposure to light.

The *Dimethylpyrryl-cinnamyl ketone*, $C_{15}H_{14}NO$, crystallises from boiling alcohol in yellow plates or needles, melting at 166° .

Thus the existence of α - β -dimethylpyrroline in animal oil is probably proved, which does not of course exclude α - α' -dimethylpyrroline and the 171° boiling α - β' - and the yet unknown β - β -dimethylpyrroline, which seem worth seeking for.

The author and Zimmerman (Ber. **19**, 200) collected the 170°—171° pyrroline fraction and the 155 fraction, from the latter of which they supposed β - β -dimethylpyrroline could be obtained. The following research disproved this.

The 154°–156° fraction was carefully obtained, but proved to be a mixture of 117°–148° α -methylpyrroline and of 165° dimethylpyrroline.

The *c*-acetyl- α -methylpyrroline melted at 85°–86°, the respective cinnamyl ketones at 193° and 166°.

The 171°—172° fraction gave on analysis figures equal to trimethylpyrroline, $C_7H_{11}N$.

The *cinnamyl ketone* crystallised in clear yellow plates, melting at 142° , analysis gave $C_{16}H_{17}NO$, trimethylpyrrol-cinnamyl ketone. The author admits the evidence of trimethylpyrroline in the 170° – 172° fraction is, however, not so clear as that of Ciamician and himself (Ber. **14**, 1001), when from the higher boiling point pyrrolines, the fractions 181° – 182° , 186° – 190° , and 190° – 193° gave a similar $C_7H_{11}N$, and further a *c*-isopropylcinnamyl ketone of the same melting point, 142° was obtained, isomeric with the above compound, but not identical.

Dr. Fock examined the respective crystals, and submitted a report showing the compound in question was in rhombic prisms, the angles measuring $74^{\circ} 52'$, while the angle of crystals of *c*-isopropylcinnamylpyrroline measured 70° , a marked difference of $4^{\circ} 52'$, and establishing the individuality of each ketone.

The author concludes with reference to the imperfect nature of the chain of evidence, owing to the impurity of the original substance.—D. A. S.

IV.—COLOURING MATTERS AND DYES.

On the Action of Diamines on Diacetones. A. Combes. Compt. Rend. **103**, 1252–1255.

REFERRING to his previous investigations on the action of the fatty and aromatic diamines on diacetones, of the type of acetylacetone, and the conversion of these products into quinoline derivatives, the author continues his work on these bodies. The action of ethylene diamine, *m*-phenylene diamine, *m*-cresylene diamine, and benzidine on acetylacetone have been studied.

On mixing one molecule of ethylene diamine and two molecules of acetylacetone a strong reaction takes place, and the mixture becomes hot, with elimination of water and formation of a white crystalline mass which melts at 111° C. Distilled in vacuo it yields a body having the following formula:—

The hydrogen atoms of the radicle $\text{CO} - \text{CH}_2 - \text{C} = \text{N}$, which behaves as an acid, can be replaced by metals, for instance by copper, yielding the compound $C_{12}H_{13}N_2O_2Cu$. Mineral acids in an aqueous solution split up the compound into acetylacetone and ethylene diamine, but by the action of hydrochloric acid in alcoholic solution, a dihydrochloride may be obtained.

The action of *m*-cresylene diamine (m. p. 99°) on acetylacetone and the subsequent treatment with sulphuric acid did not yield phenanthroline as anticipated, but amido-trimethylquinoline, melting at 191° .

In this case only one molecule of acetylacetone acts upon one molecule of the diamine—

Platino and mercurio double chlorides and chromate of the quinoline base were prepared.

From the amido-quinolines a new class of colouring matters has been prepared.—O. J. S.

On Piperazines. C. A. Bischoff. Ber. **22**, 1774–1777. REBUFFAT describes an acid which, according to him, is—

This formula, however, the author asserts belongs to a body obtained from piperazine. Abenius prepared another compound to which he ascribes the same constitution. Comparative studies have, however, shown that Rebuffat's acid is—

whilst Abenius's acid is—

The author further proposes to represent the position of the carbon atoms in the following way:—

and to call a methylene-group, in which two hydrogens are replaced by oxygen, an *Ac*-group. For instance:—

Diphenyl- α - β -diacipiperazine

Diphenyl- α - δ -diacipiperazine

Diphenyl- α - γ -diacipiperazine

—A. L.

On Hydrated Piazines of the Aromatic Series. C. A. Bischoff. Ber. **22**, 1777–1783.

DIPHENYLPYPERAZINE was first obtained by Hofmann by the action of ethylenbromide on aniline. The yield is, however, very poor. The author improved the method by using equivalent molecules of ethylenbromide and aniline, and adding so much dry sodium carbonate or acetate as is necessary to fix the hydrobromic acid produced in this reaction. The yield was 80 per cent. The melting point of the pure base is 163.5° C. Its constitution is—

Nitrous acid forms a nitroso product, which on reduction yields a diamido compound—

Diazo compounds combine with diphenylpiperazine and form colouring matters. The product formed by coupling diazo-benzene sulphonic acid with it is a yellow powder, dyeing wool and silk a pure yellow. The diazo compound of α -naphthylamine sulphonic acid is a tetrazo colour which dyes wool and silk a claret red.

If *p*-diamidodiphenylpiperazine be diazotised and conjugated with naphthylamine and naphthol-sulphonic acids, colouring matters are obtained which dye unmordanted cotton directly. The combination with naphtholdisulphonic acid (*R*-salt) forms a beautiful blue violet.

By the action of benzyltrichloride or diphenylpiperazine a green colouring matter similar to Malachite green was obtained.

Diorthotolylpiperazine—

melts at 174° C., and crystallises in needles from alcohol.

Diparatolylpiperazine forms prisms from benzene, melting at 187°—188° C.

Di- α -naphthylpiperazine—

forms prisms from chloroform, melting at 265° C.

Di- β -naphthylaminepiperazine had not so far been sufficiently purified for analysis.

Diparamethylhydroxydiphenylpiperazine—

obtained from paranisidine and ethylenebromide, melting point 233° C.

Dipara-ethylhydroxydiphenylpiperazine melts at 218° C. —A. L.

On Mono-acipiperazines. C. A. Bischoff and O. Nastvogel. Ber. 22, 1783—1786.

By the action of monochloroacetic acid on ethylenediphenyl diamine diphenylmono-acipiperazine was obtained—

It was necessary to add as much sodium acetate as is required to neutralise the hydrochloric acid formed by the reaction in order to obtain a good result. The action takes place at 160°—170° C. The substance melts at 148° C., and is soluble in most solvents with the exception of water.

Mono-acetylthylenediphenyldiamine—

melting at 128° C., and *Diphenylpiperazine*, were obtained as by-products.

By the action of one molecule of acetic anhydride on ethylenediphenyldiamine at 120°—130° C., *Mono-acetylthylenediphenyldiamine* (m. pt. = 128°), *acetanilide*, *diphenylpiperazine*, and *diacetylthylenediphenyldiamine*—

melting at 158° C., were formed.

Diparatolylmono-acipiperazine—

melting at 168.5° C., was prepared like the analogous phenyl compound. —A. L.

α - γ -Diacipiperazines. C. A. Bischoff and O. Nastvogel. Ber. 22, 1786—1792.

100 grms. of monochloroacetic acid, 120 grms. of sodium acetate in crystals, and 100 grms. of orthotoluidine were mixed, and heated on the water-bath until all was melted. Then 120 cc. of water were added and the mixture heated until the layer of oil ceased to increase, and a drop solidified on cooling. The tolylglycine, $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{COOH}$, melts at 149°—150° C. When heated in a retort to 140°—150° C. in a current of hydrogen until water ceases to be formed, no evolution of carbonic acid was perceptible. The temperature is then to be increased to 220° C. A light yellow mass is formed, which when mixed with ether is changed into a white powder. By dissolving it in chloroform and precipitating with alcohol the piperazine was obtained in a pure state. Orthoditolyl- α - γ -diacipiperazine—

melts at 160° C.

Para-ethylhydroxyphenylglycine—

is obtained from phenetidine hydrochloride and monochloroacetic acid in aqueous solution. It melts at 163° C. If heated rapidly it decomposes with much more considerable evolution of carbonic acid than if heated slowly. The following products are formed on heating this compound.

Paraethylhydroxymethylaniline, $\text{C}_2\text{H}_5 \cdot \text{O} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CH}_3$.

Diparethyldiethoxyphenyl- α - γ -diacipiperazine—

melting at 265° C.

Glycolyldi-ethylhydroxyanilide—

and an acid, probably—

A method is given for the separation of these substances, for which the original must be consulted. —A. L.

Some Homologues of Diphenyl- α - γ -diacipiperazine.

O. Nastvogel. Ber. 22, 1792—1795.

Alpha-anilidopropionic ethylether—

obtained by the action of alphas-bromopropionic ether on aniline. Its boiling point is 272° C.

Alpha-anilidopropionic anilide—

Melting point = 126° C.

Diphenyl- α - γ -dimethyl- β - δ -diacipiperazine—

melts at 180°—181° C., and was prepared by the action of acetic anhydride on alpha-anilidopropionic acid. A second isomeride, more easily soluble in ether, and melting at 147°—148° C., was obtained, the constitution of which has yet to be ascertained.

Alpha-anilidobutyric ethylether—

It boils at 278° C.

Alpha-anilidobutyric acid was prepared by saponifying the ether. It melts at 139°—140° C.

Diphenyl- α - γ -diethyl- β - δ -diacipiperazine—

was prepared like the analogous compound before described. It melts at 260° C.—A. L.

On Diphenyl- α - γ - and α - δ -diacipiperazine. A. Hausdörfer. Ber. 22, 1795—1804.

On heating 2 mols. of aniline with 1 mol. of chloracetic acid on a saltwater-bath, the following products were isolated:—

Phenylglycine.

Phenylimidodiacetic acid $\text{C}_6\text{H}_5\cdot\text{N}:(\text{CH}_2\cdot\text{CO}\cdot\text{OH})_2$. The latter melts and decomposes at 150°—155° C.

An acid, $\text{C}_6\text{H}_5\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{N}(\text{C}_6\text{H}_5)\cdot\text{CH}_2\cdot\text{COOH}$, melting at 211°—213° C.

Phenylglycine anilide, melting at 111·5° C.; and

Diphenyl- α - γ -diacipiperazine—

melting at 263° C.

If equal quantities of aniline, chloracetic acid, and dehydrated sodium acetate be heated in the oil bath with inverted condenser at 110°—120° C. for half an hour, and for 3—4 hours at 140°—150° without the inverted condenser:—

Acetylphenylglycine—

m.pt. = 192°—193° C., an acid $\text{C}_{16}\text{H}_{16}\text{N}_2\text{O}_3$ melting at 211°—213° C., and identical with the one above described; *Phenylglycine anilide*, m.p. 111·5° C.; and *Diphenyl- α - γ -diacipiperazine* are obtained.

If equal molecules of aniline and chloracetic acid be heated with ordinary sodium acetate *Phenylglycine* and *Phenyl-imido-diacetic acid* are obtained. By heating the latter gradually with the molecular proportion of aniline to 170°—180° C., *Phenyl-imido-diacetic acid mono-anilide* is formed:—

(m.pt. = 218° C.).

Molecular weights of phenylglycine anilide and chloracetic ether heated with dehydrated sodium acetate produce phenyl-imido-diacetic anilide ethylether—

melting at 121°—122° C.

Diphenyl- α - δ -diacipiperazine—

was obtained from phenylglycine anilide, chloracetic ether, and sodium ethylate.

Needles, melting at 152°—153° C.

Some more derivatives: Bromoacetylphenylglycine and Phenylglycine phenylglycine—

are described.—A. L.

α - β -Diacipiperazines and some abnormal Reactions in the Formation of Piperazines. C. A. Bischoff and O. Nastvogel. Ber. 22, 1804—1808.

Diacipiperazines of the general formula—

were obtainable by the action of oxalic acid on the secondary bases $\text{XXH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NH}\cdot\text{X}$. Thus:—

Diphenyl- α - β -diacipiperazine—

was obtained by the action of oxalic acid on ethylenediphenyldiamine at 200° C., and formed colourless plates melting at 258° C.

The homologous body—

Diorthotolyl- α - β -diacipiperazine—

($\text{CH}_3:\text{N}$ in both nuclei = 1:2). It melts at 183·5°—184° C.

By the action of oxalic acid on paratolylglycine toluidide, diparatolyl-diacipiperazine was obtained amongst other products—

Oxalic acid acting on malonyldianilide produces more complicated substances. Malonic ethylether forms with ethylenediphenyldiamine diphenylpiperazine.

Monochloracetic acid combines with α -naphthylamine when mixed at the ordinary temperature, and forms an addition product melting at 90° C. When heated an amorphous body was obtained with the approximate formula—

α -naphthylglycine, $\text{C}_{10}\text{H}_7\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, is formed by thoroughly mixing the base, monochloracetic acid, and sodium acetate and heating to 100° C. It crystallises from alcohol, and melts at 198°—199° C. When heated in an atmosphere of carbonic acid to 230° C. an anhydride—

is formed, melting at 268°—269° C.—A. L.

On some Derivatives and Reactions of Tetramethyldiamidobenzophenone. M. Nathansohn and P. Müller. Ber. 22, 1875—1901.

Dibenzoyldimethyldiamidobenzophenone—

Equal parts of tetramethylbenzophenone and benzoylchloride were heated in the oil-bath to 190° C. The colour of the mixture changed through blue and green into dark red. Methylchloride escaped abundantly as a gas. After three hours the reaction appeared to be finished. The red mass was powdered, the excess of benzoylchloride removed by washing with sodium carbonate solution, and the residue was crystallised from alcohol. Light-brown plates were obtained, melting at 102° C. Excess of benzoylchloride produced the same body. Attempts at saponification proved fruitless. The production of the corresponding acetyl-compounds by the action of acetylchloride was not successful.

Tetramethyldiamidobenzophenone methyl iodide—

The ketone was heated for four hours with an excess of methyl iodide and methyl alcohol. The product of the reaction when crystallised from alcohol yielded thin light yellow crystalline scales melting at 105° C., with difficulty soluble in cold alcohol and cold water, but easily dissolved by these solvents when hot. On heating this methyl iodide-compound to 150°, methyl iodide distils over and the original ketone remains.

Reduction of the Ketone by Sodium amalgam.—*Tetramethyldiamidodiphenylcarbinol* $[(CH_3)_2N.C_6H_4]_2CH.OH$.—This carbinol crystallises in colourless prisms from ether and benzene, and melts at 96° C. Soluble with a blue colour in hot alcohol and glacial acetic acid, to a colourless liquid in benzene and ether. The hydrochloride, the platinum double salt, and the pterate are described.

Tetramethyldiamidodiphenylcarbinol methyl iodide—
 $CH[C_6H_4N(CH_3)_2]_2OI$

crystallises from hot alcohol in colourless plates, melting at 195° C., and decomposing at 240° C., methyl iodide being evolved. It is little soluble in cold, but abundantly in hot alcohol and water. Its preparation is the same as that of the corresponding ketone compound.

Tetramethyldiamidodiphenylmethane—
 $CH_2[C_6H_4.N(CH_3)_2]_2$

was obtained by distilling the ketone with 10 times its weight of zinc dust in an atmosphere of hydrogen. The distillate melted after purification and crystallisation at 90° C.

Tetramethyldiamidotetrabromobenzophenone—
 $CO[C_6H_2Br_2N(CH_3)_2]_2$

was prepared by treating the glacial acetic acid solution of the ketone with bromine. It melts after purification at 172° C., and is easily soluble in hot alcohol, but with difficulty in benzene and ether.

Tetramethyldiamidonitrobenzophenone—
 $(CH_3)_2N.(NO_2)C_6H_3.CO.C_6H_4.N(CH_3)_2$

This compound was obtained by adding to a solution of the ketone in concentrated sulphuric acid the molecular proportion of sodium nitrate. After heating for a few hours on the water-bath the mixture was poured (after cooling) into water containing ammonia; a yellow precipitate was formed. This, after recrystallisation, melted at 144° C. The compound is easily soluble in hot alcohol and benzene, with difficulty in cold alcohol and benzene and in ether.

By reducing this compound with stannous chloride and hydrochloric acid—

Tetramethyldiamidobenzophenone—
 $CO \begin{cases} C_6H_3NH_2.N(CH_3)_2 \\ C_6H_4.N(CH_3)_2 \end{cases}$

was obtained, melting at 82° C., soluble in boiling alcohol and benzene. The pterate and platinum double salt were prepared.

Condensation products of Tetramethyldiamidodiphenylcarbinol—

$[(CH_3)_2N.C_6H_4]_2CH.C_6H_4.NH_2$

Tetramethyltriamidotriphenylmethane—

This base was prepared according to the method of the Badische Anilin und Soda Fabrik. Recrystallised after purification from alcohol, it forms small white needles melting at 65° C., soluble in alcohol, ether, and benzene. The hydrochloric acid salt, the platinum double salt, and pterate are described. Its benzoyl compound—

$[(CH_3)_2N.C_6H_4]_2CH.C_6H_4.NH(C_7H_5O)$

was prepared by heating it with benzoic anhydride at 150° C. It forms small plates, nearly colourless, melting at 128° C., soluble in hot alcohol and benzene, with difficulty soluble in

ether. The methyl iodide compound, $CH[C_6H_4.N(CH_3)_2]_2I$, was obtained in the usual way, and melts at 172° C. It is soluble in alcohol and hot water, but nearly insoluble in ether and benzene.

Victoria blue B. was prepared by mixing 10 parts of tetramethyldiamidobenzophenone, nine parts of α -phenyl-naphthylamine, and seven parts of phosphorus oxychloride. A reaction takes place, which is finished by gradually heating to 110° C., and keeping up this temperature for 15 minutes. The colouring matter was purified in the usual way, and finally crystallised from a mixture of benzene and alcohol. It is easily soluble in hot water and alcohol, with difficulty in benzene, and very little in ether. Its formula is probably either—

Caustic soda precipitates the free base as a black substance melting at 95° C., which could not be crystallised. Its formula is $[(CH_3)_2N.C_6H_4]_2C(OH).C_{10}H_6.NH.C_6H_5$. The platinum double salt and pterate were prepared in the usual way. On reducing the Victoria blue solution with zinc dust and hydrochloric acid, the *leuco compound* was obtained. On addition of excess of caustic soda a light blue flocculent precipitate, $[(CH_3)_2N.C_6H_4]_2CH.C_{10}H_6.NHC_6H_5$, is formed, melting at 125° C., which could not be crystallised. Its pterate and platinum double salt are described.

Victoria blue IV. R. is a condensation product of tetramethyldiamidobenzophenone with methylphenyl- α -naphthylamine. Its preparation is the same as that of the above-described compound. Its formula is $C_{34}H_{34}N_3Cl$. The free base was obtained by precipitation with sodium carbonate as a black substance which, after redissolving and precipitation, acquired finally a brick-red colour. It melted at 77° C. It is with difficulty soluble in benzene, easily in alcohol. The leuco-base was prepared in the same way as before described. It could not be crystallised, though soluble in alcohol and ether. It is sparingly soluble in benzene.

Victoria blue B. was treated for six hours with concentrated hydrochloric acid at 230°–250° C. On opening the tube a gas, methylchloride, escaped. The contents of the tube consisted of a dark-brown liquid and a black resinous substance. The liquid was diluted with water, and then caustic soda added. A light grey precipitate was formed, from which, by treatment with steam, dimethylaniline was separated. The solid residue was purified by repeated solution in cumene, and precipitation with petroleum spirit. Its formula is $C_{23}H_{18}N_2O$, and its constitution is expressed by either the formula $NH_2C_6H_4.CO.C_{10}H_6(NH)C_6H_5$ or $NH_2C_6H_4.CO.C_6H_4(NH)C_{10}H_7$. It melts at 92° C.

Victoria blue B. was further distilled by itself, with soda lime and with zinc dust in an atmosphere of hydrogen. In all cases dimethylaniline and a dark yellow oil boiling at 330°–335° C. were formed. The latter product is probably naphthylphenylamine. This compound is described as a white body melting at 60° C., and forming an acetyl compound melting at 114°–115° C. The authors succeeded in preparing the same acetyl derivative from the substance they obtained, which must, therefore, be considered as identical with phenyl- α -naphthylamine.—A. L.

Syntheses in the Oxazine Series. L. Knorr.

PATENTS.

Improvements in the Production of Green and Bluish-Green Colouring Matters. O. Imray, London. From the "Farbwerke vormals Meister, Lucius, and Brüning," Höchst, Germany. Eng. Pat. 14,822, October 15, 1888. 8d.

This is an extension of the Eng. Pat. 12,796 of 1888 (this Journal, 1889, 701), and describes the sulphonation of *m*-amido-leuco bases of the general formula—

and their subsequent oxidation into colouring matters. The same colouring matters are obtained by sulphonating the corresponding carbinols—

The following examples are given of the two methods. 30 kilos. of *m*-amidotetra-ethylamidotriphenyl methane are dissolved in 150 kilos. of sulphuric acid containing 20 per cent. of SO_3 . The temperature of the melt is raised to 90° – 100° until a sample dissolves to a clear solution in a 3 per cent. solution of ammonia. The whole is then converted into the calcium or sodium salt. In the case of compounds like *m*-amido-dibenzylidimethyldiamidotriphenyl methane (*i.e.*, with benzyl or phenyl, &c. in the amido group)—

the sulphonation is performed at 60° , and continued until a sample dissolves easily in water and gives a violet solution with dilute ammonia. The oxidation is effected by means of the peroxides of manganese, lead or barium, together with a mineral acid. The colouring matters obtained are copper-red powders with a metallic lustre, easily soluble in water. Excess of a mineral acid turns the solution green. Cold caustic soda or boiling dilute ammonia, or soda, does not destroy the colour, and the blue solution only turns violet on boiling with caustic soda. Wool and silk are dyed in an acid-bath a bluish-green shade, and the shades are very fast. The carbinols are sulphonated as follows, and then yield the same dyestuffs. 20 kilos. of *m*-amido-tetra-ethylamidotriphenyl carbinol are dissolved in 100 kilos. of monohydrate and heated to 70° – 80° , until soluble in ammonia with a pure blue colour. The melt is then converted into the calcium or sodium salt.—T. A. L.

The Manufacture or Production of a New Sulphone or Diethyl Sulphone Methyl Ethyl Methane. B. Willcox, London. From the "Farbenfabriken vormals Friedrich Bayer and Co.," Elberfeld, Germany. Eng. Pat. 16,333, November 10, 1888. 6d.

The three following methods are given for the production of the new sulphone which is a substance melting at 76° , crystallising from water in shining laminae. It is slightly soluble in cold water, but more readily in hot water, alcohol, ether or benzene. It is odourless and has a slightly bitter taste.

1. Methyl ethyl ketone is added to the calculated quantity of ethyl mercaptan and dry hydrochloric acid gas passed through the mixture. After standing some hours it is poured into water, the oil which separates dried over calcium chloride and rectified. It boils without decomposition at 198° – 203° , and is converted into the sulphone by oxidation with permanganate mixed with a small quantity of acid. When the permanganate is decolourised the solution is boiled down and filtered, when the sulphone crystallises out on cooling.

2. Dry hydrochloric acid gas is passed through a mixture in molecular proportions of acetaldehyde and ethylsulphhydrate. The condensation product boils at 186° – 188° , and is converted by oxidation into diethylsulphone methyl

methane. This crystallises in shining prisms melting at 75.5° , and is readily soluble in water and other solvents. Seven parts of the product are dissolved in 20 parts of water, 2.5 parts of solid caustic soda and 5 parts of ethyl iodide are then added, and the whole boiled for an hour with an inverted condenser. On cooling the solution, diethylsulphone methyl ethyl methane separates out.

3. Propionic aldehyde in equivalent quantity may be employed in place of the acetic aldehyde mentioned in (2). The condensation product is an unpleasantly smelling oil boiling at 190° – 200° . The diethylsulphone ethyl methane therefrom melts at 77° , and is converted into diethylsulphone ethylmethyl methane as described above, methyl iodide being used in place of the ethyl iodide there mentioned. (This Journal, 1889, 610.)—T. A. L.

A New Manufacture of Dyestuffs. C. D. Abel, London. From the "Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 17,333, November 28, 1888. 6d.

By heating two molecules of *m*-xylydine or ψ -cumidine with two molecules of sulphur, sulphuretted hydrogen is given off and bases containing sulphur are obtained which can be diazotised and combined to form dyestuffs with phenol and its homologues, resorcinol, resorcinol ethers, orcinol, naphthol, dihydroxy-naphthalene, phenylene diamine, toluylene diamine, chrysoidines, Bismarck Brown, naphthylamine and its alkyl derivatives and their sulphonic or carboxylic acids. As some of these combinations are scarcely soluble in water the patent describes the sulphonation of the sulphur bases and subsequent diazotisation and combination with amines or phenols. The quantities given for the preparation of the sulphur bases are: 40 kilos. of *m*-xylydine are heated with 10 kilos. of sulphur so long as sulphuretted hydrogen is given off. The melt is allowed to cool slightly and is then poured into sulphuric acid diluted with an equal bulk of water. The sulphate of the new base separates in yellow flakes. 20 kilos. of this are dissolved in 125 kilos. of hydrochloric acid of 12° B. and poured into 1,000 litres of water. 14 kilos. of sodium nitrite in 50 litres of water are then added and the whole poured into an alkaline solution of α -naphthol disulphonic acid. The solution is then boiled and the dyestuff precipitated by means of salt. The colouring matter dyes unmordanted cotton a red shade.

These dyestuffs are higher homologues of the primuline series (A. G. Green, this Journal, 1889, 383). (See also P. Jacobson, Ber. 22, 330–335; L. Gattermann, this Journal, 1889, 275 and 608; W. Pfützing and L. Gattermann, this Journal, 1889, 608; R. Anschütz and G. Schultz, Ber. 22, 580–586.)—T. A. L.

Manufacture of Bluish-Black Colouring Matters. S. Pitt, Sutton. From L. Casella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 18,425, December 17, 1888. 6d.

According to Eng. Pat. 9214 of 1885 (this Journal, 1886, 427), the patentees have a process for preparing azo dyestuffs of the formula—

The present invention describes the substitution of other naphthol and naphthylamine mono- and disulphonic acids and also of dihydroxynaphthalenes and their sulphonic acids for the naphthylamine and naphthol sulphonic acids known at the time of the patent 9214. (1.) In place of the naphthylamine sulphonic acids previously used the following are employed: β -naphthylamine sulphonic acid F, Eng. Pat. 12,908 of 1886 (this Journal, 1887, 725), β -naphthol- δ -sulphonic acid, Eng. Pat. 8265 of 1887 (this Journal, 1888, 431), or the amido acids obtained by heating with ammonia the naphthol disulphonic acid of Ger. Pat. 38,281 or the α -naphthylamine- δ -sulphonic acid of Ger. Pats. 40,571 and 45,776. (2.) For the naphthol sulphonic acid it is proposed to use instead naphthol sulphonic acid F, Eng. Pat. 12,908, naphthol mono- and disulphonic acids S, Ger.

Pat. 40,571, naphthol sulphonic acid, Ger. Pat. 38,281, or 6-naphthol-5-disulphonic acid, Eng. Pat. 8265. (3.) The naphthols can also be replaced by dihydroxynaphthalenes and their sulphonic acids (Griess, Ber. **13**, 1959). Ger. Pats. 41,931, 40,893, and 12,261. The tetrazo derivatives mentioned in Eng. Pat. 9214 can also be combined with amines alone and give dyestuffs.—T. A. L.

Production of a New Violet Dye or Colouring Matter. T. R. Shillito, London. From J. R. Geigy and Co., Basel, Switzerland. Eng. Pat. 2941, February 19, 1889. 4d.

TWENTY kilos. of gallamide and 30 kilos. of nitroso-dimethylaniline hydrochloride are heated in a solution of acetic acid. The colouring matter separates in small greenish crystals. It dissolves in water and alkalis with a violet, and in acids with a red colour. For printing purposes it is converted into the sodium bisulphite compound and in dyeing as well as in printing requires a chromium or other mordant.—T. A. L.

Improvements in the Manufacture of Mixed Azo Colours. H. H. Leigh, London. From R. G. Williams, Albany, U.S.A. Eng. Pat. 12,767, August 13, 1889. 6d.

WHEN one molecule of a tetrazo-compound is combined with one molecule of a naphthylamine or its sulphonic acid, an insoluble intermediate compound is obtained. A new class of these intermediate bodies is obtained by combining one molecule of a naphthalene-azo-naphthylamine or sulphonic acids of the same with one molecule of a tetrazo-compound, and reacting on them with another molecule of an amine or a phenol. 25 lb. of sodium naphthienate are dissolved in 50 galls. of water, and 30 lb. of hydrochloric acid of 22° B. are added. The mixture is cooled with ice and diazotised with 7 lb. of sodium nitrite in 35 lb. of water. 25 lb. of sodium naphthionate and 15 lb. of sodium acetate in 20 galls. of water are then added, and the reaction is complete when the whole forms a clear bright scarlet solution. This product is allowed to react on tetrazo-ditolyl (from 32 lb. of tolidine sulphate and 14 lb. of sodium nitrite) in presence of sodium acetate. When combined 25 lb. of sodium naphthionate in 60 galls. of water are added. The colour is formed very slowly and the reaction is complete when the dye tests show no improvement. The whole is then boiled, sufficient caustic soda added to convert the dyestuff into its sodium salt, precipitated with salt, filter-pressed, and dried. It dyes unmordanted cotton a bright red in an alkaline or soap bath, producing shades similar to Benzopurpurin 4B. The formula of the compound is—

The several constituents can be varied according to well-known methods.—T. A. L.

Improvements in the Manufacture of Indigo by the Application of Electricity. F. Hughes, London. From E. J. McDonald, Champaran, Bengal. Eng. Pat. 13,636, August 29, 1889. 8d.

A PROCESS for passing an electrical current through an indigo vat during the beating process, by which it is claimed that the yield and colour of the indigo are increased to an appreciable extent. The specification contains a drawing of the vat.—T. A. L.

Manufacture of New Derivatives of Tannin and Catechin and of Colouring Matters obtained therefrom. J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran, Bâle, Switzerland. Eng. Pat. 15,360, September 30, 1889. 4d.

By reacting with the nitroso derivatives of the tertiary aromatic amines on tannins, catechol ("catechin") and gallic acid, colouring matters have been obtained to which

the name *Gallocyanines* was given. Their preparation is described in the specification No. 4899, 1881. The present invention describes the preparation of new gallocyanines by reacting with the nitroso derivatives of tertiary aromatic amines on the products obtained by condensing tannin and "catechin" with primary aromatic amines. The preparation of "gallonaphthylamide" is described. One part of tannin is dissolved in three parts of fused naphthylamine and the melt gradually raised to 150°–180°. A slight ebullition indicates the end of the reaction. The mass is then allowed to cool, and whilst still hot is run into petroleum spirit or other solvent when the gallonaphthylamide remains undissolved. Colouring matters are obtained herefrom by the action of nitrosodimethylaniline hydrochloride as mentioned above. The products are scarcely soluble in ordinary solvents, and have to be employed as bisulphite compounds, when they dye mordanted fibres violet shades.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENTS.

An Improved Process and Composition for Extracting Oil from and Cleaning Cotton-Waste. W. Mitchell and S. Picard, London. Eng. Pat. 17,628, December 3, 1888. 6d.

See under XII., page 991.

Improvements in Washing Wool and in Treating and Utilising the Washings. H. W. Langbeck, Loughton. Eng. Pat. 66, January 2, 1889. 6d.

See under XII., page 991.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Dyeing of Cotton-Valvet. E. Lindinger, Wollen und Leinen-Industrie, 1889, 9, 721.

THE goods are first singed and then boiled with a 0.5 or 1 per cent. solution of soda; after rinsing they are ready for dyeing.

White.—The goods are further treated in the jigger with bleaching solution, soured and washed.

Pure White is obtained by bleaching as above, and afterwards passing the goods through a weak soap-bath containing a little Methyl violet or a red shade of Soluble blue.

Pale Grey is dyed in several ways. Böhm's silver-grey paste is applied with alum and acetic acid. A more usual plan consists in mordanting with gall-nuts or tannic acid, fixing with copperas and dyeing with Methylene blue and a little alum. With stronger baths sumae- or logwood-extract is also added, *Medium* and *Dark Greys* being obtained. Dark shades of grey are also obtained by grounding the cloth with Caehon de Laval, rinsing, dyeing with Benzoazurin and passing through a bath of copper sulphate.

Pink.—Fine shades are produced with Rhodamine and alum on cotton mordanted with tannic acid and an antimony salt. Safranin in an alum bath, and Rose bengale or Ploxine in a borax bath, also give nice shades. A fast pink is dyed with K. Ochler's Fast pink G.

Bright Red is dyed with Brilliant congo in a potash-soap bath. A very fiery shade is obtained with Crocein scarlet in an alum bath, but the dye is not fixed. Magenta dyed on the tannic acid mordant yields a bluer shade of red.

Bordeaux.—The cloth is dyed with Benzopurpurin, Brilliant congo, or Diamine red, and, for a full red tone, topped with Safranin or Magenta, or with Diamine blue, Violet black or Benzoazurin for a darker shade. Scarcely so fast are the shades obtained by dyeing with Magenta and Bismarek brown or Chrysoidine on cotton mordanted with tannic acid and antimony, and saddening with Neutral blue, logwood, or Methyl violet.

Dark Bordeaux is obtained by grounding either with Cachou de Laval, catechu and bichrome, sumae and iron or logwood, and an alumina or tin mordant, rinsing, and dyeing either with Brilliant congo and Diamine blue, followed by a topping with Magenta, or with Magenta, Bismarek brown, Neutral blue or logwood, after mordanting with tannic acid, if some form of that body has not been already applied. Of these dyestuffs, those of the substantive class alone yield shades fast to rubbing.

Buff is dyed with Brahma orange or with Chrysamine R. in a soda-soap bath.

Orange is obtained with Brahma orange, Toluylene orange, or Mikado orange in an alkaline bath.

Pale Brown.—A ground colour is dyed with Cachou de Laval or Catechu, the cloth being further dyed with a mixture of brown and blue dyestuffs of the substantive class, such as Cotton brown A and Benzoazurin 3 G. The shade is considerably brightened by subsequently dyeing with Bismarek brown or Auramine. **Dark Browns** are obtained in a similar manner on a darker ground. The darker the shade the greater the necessity for topping with Bismarek brown.

Yellow.—A delicate shade is obtained with Auramine in an alum bath. Chrysamine in a sodium phosphate bath yields a *Chrome Yellow*.

Olive.—The cloth is grounded with sumae and bark, fixed with copperas and alum, and dyed with Auramine, Bismarek brown and Methylene blue or a basic green.

Green is dyed (in an alum bath) with a basic green dyestuff on cotton mordanted with tannic acid, shading being effected with Methylene blue or Auramine.

Dark Greens are dyed in the same way as the light greens after bottoming the cloth with sumac and bark, fixed with copperas and alum.

Pale Blue is dyed with Methylene blue in an alum bath.

Darker Blues are obtained with Victoria blue or a mixture of Methylene blue and violet on cloth mordanted with tannic acid or previously dyed in an alkaline bath with Benzoazurin G.

Navy Blue is produced by dyeing with Benzo-black-blue or Violet black in an alkaline bath, and topping with Methylene blue or violet.

Mauve.—A pure Methyl violet such as Poirrier's mauve 250 N should be used. The finest shade is obtained by preparing with oleine (in the proportion of 1 to 20) or resin-soap, drying, fixing with alum and then dyeing. Gall-nuts or tannic acid can be used to mordant only for darker shades. Dark shades are dyed on a tannin-antimony mordant, brighter ones on a tannin-tin mordant saddened with logwood or Neutral violet.

Prune is obtained by bottoming with Cachou de Laval, then mordanting with tannic acid or sumae, fixing with an antimony salt, and dyeing with a basic violet. A very fast prune is dyed with Violet on cloth previously dyed with Violet black.

All the dyeing operations are conducted in the dye-jigger. —E. B.

A New Chrome Mordant Process. G. Saget. Monit. Scient. 1889, 983.

HITHERTO chromic acid has been reduced on the woven fabric by Koechlin's hyposulphite of soda process. The author finds that the reduction can also be effected by hydrosulphurous acid.

Cloth treated with potassium bichromate and dipped into calcic hydrosulphite becomes at once green, and the chromic oxide then attracts the colouring matter.

On the large scale the goods are padded with a mixture of 100 grms. of sodium bichromate, 900 grms. of water, and 100 cc. of a 10 per cent. solution of tragacanth, dried in the dark, and then passed for a minute through a calcium hydrosulphite bath at 40° C. The bath is prepared by adding to 80 litres of water and 6 kilos. of caustic lime a solution of zinc hydrosulphite which has been obtained by the action of 4 kilos. of zinc dust on 40 litres of sodium bisulphite of 30°. The hydrosulphite acts slowly in the cold, but immediately at 40° C.—W. M.

PATENTS.

Improvements in Apparatus for Printing Textile and other Fabrics. J. and A. S. Young, Ramsbottom. Eng. Pat. 18,263, December 14, 1888. 6d.

This invention relates to the construction of a "duplex" printing machine. The cloth to be printed passes downwards between two "transfer" rollers covered with india-rubber or an elastic composition. The pairs of engraved copper rollers are mounted in the same plane and at opposite sides of the "transfer" rollers. These "transfer" rollers receive the colour from the engraved rollers, and deliver it to the cloth as it comes into contact with them. Suitable arrangement is made for washing the transfer rollers after they have given their impression so that they are caused to present a clean surface to the engraved rollers after each revolution. Any convenient number of colours may be printed.—E. B.

An Improved Process of, and Apparatus for Dyeing Cotton-Yarn. H. Recker, Zittau, Germany. Eng. Pat. 18,780, December 22, 1888. 8d.

This is a continuous process for dyeing cotton warps aniline black, and finishing the same.

The warps are passed through a tank of boiling water, squeezed by a pair of rollers, and passed through a bath of aniline hydrochloride till thoroughly saturated, then they are again squeezed and dipped into a solution of potassium chromate. They next pass in a zig-zag fashion over a system of rollers contained in a tower of an inverted U shape, in which they are oxidised for about 45 seconds by hot air, which enters at the bottom, and leaves the top of the tower through a discharge pipe. After the black has been oxidised in this manner, the yarn is washed, dressed, dried and beamed, the whole of the operations being conducted continuously as is shown in the drawing which accompanies the specification.—E. B.

Improvements in and connected with Vats or Apparatus for Dyeing, Washing, Bleaching, Scouring, or Mordanting Fibrous Materials. F. A. Blair, Galashiels. Eng. Pat. 2743, February 16, 1889. 8d.

At a little distance above the bottom of the vat there is placed horizontally a partition which is raised in the middle in the form of a cone. At the upper part of the cone there is fixed a vertical pipe into which is fitted an upper telescopic pipe, closed at the top, but with perforations at or near the same. The horizontal partition is also perforated. Two steam-pipes are placed beneath the horizontal partition and cone. One of the steam-pipes is perforated, the other terminates in a jet-nozzle directed up the central vertical pipe. The fibrous material to be operated upon is placed in the vessel around the central pipe, or it may be placed, instead, in a cage of which the partition cone and the central pipe form part and which can be lowered into or raised out of the vat.

The central steam-jet, when used alone, causes the liquid in the vessel to pass up the central pipe and become sprayed out at the top, whence it percolates down through the fibrous materials. The other steam-pipe is used for heating purposes and may be replaced by a steam-jacket or an external fire. Drawings of different modifications are attached to the specification.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

New Method of Preparing Nitrites of the Alkalis. G. A. Le Roy. *Compt. Rend.* **108**, 1251—1252.

THIS method is based on the reaction which ensues when barium sulphide is heated with an alkaline nitrate, barium sulphate and the nitrite of the alkali being formed, according to the following equation:—

The finely powdered barium sulphide is carefully mixed with the nitrate and heated to redness in an iron dish, stirring the mixture well. As the reaction takes place rapidly, it is well to add some barium sulphate in order to avoid too much decomposition. The melt is treated with water and the nitrite separated by filtration.—O. J. S.

PATENTS.

Improvements in the Manufacture of Chlorine. T. Parker and A. E. Robinson, Wolverhampton. *Eng. Pat.* 17,367, November 29, 1888. *4d.*

Tetrachlorides of iron and zinc obtained in the galvanising and pickling of iron are electrolysed, the chlorine evolved being collected and utilised in any known way. The electrodes may be of carbon or platinum, or the negative electrode may be of the metal forming the base of the salt electrolysed. The chloride solution, which may contain from 10 to 50 per cent. of chloride, is, if acid, first neutralised, preferably by an alkali.—S. G. R.

Improvements in Generating Carbonic Acid Gas. F. Foster, Hoxton. *Eng. Pat.* 17,569, December 1, 1888. *8d.*

THE generating vessel is made in two portions, an upper and a lower, which are in communication by means of a pipe closed by a valve. Passing through both parts is a stirrer. In the upper vessel is placed the mixture of whitening and water or other material from which the carbon dioxide is to be evolved. After thorough mixing this is run into the lower vessel, where there is an inlet syphon pipe for the acid and an exit tube for the carbon dioxide. The gas is washed and passed into a gas-holder, and in order that the spent liquors may be run out of the lower portion of the generator without the introduction of air, a branch pipe connects this with the gas-holder, so that carbon dioxide may be passed back again in the required quantity. (This *Journal*, 1888, 749.)—S. G. R.

Improvements in the Manufacture of Phosphorus. T. Parker and A. E. Robinson. Wolverhampton. *Eng. Pat.* 17,719, December 5, 1888. *4d.*

THE inventors take meta- and ortho-phosphoric acids or their salts and mix these with rather more than the theoretical quantity of carbonaceous matter, such as crushed coke. The mass is placed in an electric furnace and the resulting vapours of phosphorus condensed in water or in some other of the ordinary ways.—S. G. R.

Improvements in obtaining Chlorine. A. Campbell, London, and W. Boyd, Glasgow. *Eng. Pat.* 18,956, December 11, 1888. *4d.*

INSTEAD of passing hydrochloric acid into water or water containing manganese peroxide in suspension, it is passed into a solution of manganese sulphate, to which peroxide of manganese has been added. "The quantity of peroxide taken is sufficient, not only to cause the evolution of about one-third of the chlorine, as in the ordinary process, but also, with the aid of sulphuric acid which is added at this stage, to cause the evolution of a further large proportion of chlorine." The solutions which contain gradually increasing amounts of the sulphate, owing to frequent

additions of peroxide, are concentrated, and the separating manganese sulphate fished out. This is dissolved in water and treated with ammonium carbonate, the resulting carbonate of manganese being converted into peroxide by known methods.—S. G. R.

Improvements in the Concentration of Sulphuric Acid, and in the Apparatus employed therefor. G. Veitch, Crieff. *Eng. Pat.* 7901, May 11, 1889. *8d.*

THE glass retorts used are flat-bottomed, and made either of Bohemian or best English glass. They are arranged one above another on a stepped terrace placed within a fire flue and so connected by means of suitable tubes that the acid, which is fed in at the upper end in a constant stream, travels through the whole series and passes out, highly concentrated, from the lowest. The flue is tapered, the fires being placed at the lowest and widest end, and narrowing upwards. All the retorts can be easily seen and hence a breakage can be at once remedied. The necks of the retorts pass into a flue and are kept covered by asbestos millboard to shield them from draughts. The specification is illustrated by drawings.—S. G. R.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

New Recipes for Sèvres Porcelain. H. Hauhart, Sprechsaal, **22**, 368.

THE new porcelain at Sèvres is made of a body and glaze similar to those discovered by Salvétat at Sèvres in 1855. The porcelain contains:—

	Parts by Weight.
Silica	64—71
Al ₂ O ₃	29—23
KNaCO ₃	7—6

Salvétat's figures were almost the same:—

	China Porcelain.	Sèvres.	Sèvres.
	Parts by Weight.	Parts by Weight.	Parts by Weight.
SiO ₂	69	70	67
Al ₂ O ₃	23	26	26
K ₂ O	3	4.5	3
Na ₂ CO ₃	3

Salvétat made use of a glaze containing a high percentage of lime to increase its durability, whereas Lauth (the recent director at Sèvres) prefers the same amount of lime as is found in Chinese glazes:—

	Chinese Glaze.	Lauth's Glaze.	Salvétat's Glaze.
SiO ₂	68	66.5	51.5
Al ₂ O ₃	12	14	10
CaO	14	15.5	32
KNaO	6	3.6	5

The new porcelain, compared with the hard porcelains produced by the author, admits of more extensive decoration by means of coloured high temperature glazes.—E. E. B.

Defective Tin Glazes. Sprechsaal, 22, 370.

WHEN the white enamel cracks on drying and does not become smooth when re-baked, the contraction on drying must be diminished by fritting the materials strongly and melting them. If the enamel do not melt sufficiently easily it must be mixed with more lead oxide.—E. E. B.

Porcelain Pastes and Glazes for Table Services. Sprechsaal, 22, 477.

Alumina Lustres. Sprechsaal, 22, 577.

If vitrifiable colours be mixed with lustres the colours of the surface glaze acquire a very characteristic enamel-like appearance. They can be applied in a thick pasty condition, but are fired in the usual manner.

For this purpose alumina lustres is specially suited as, like lead, zinc and bismuth lustres, it is colourless and iridescent and allows the colour on the under surface to be visible through it. The alumina lustre is prepared by adding a solution of resin soap to a warm solution of alum. The alumina resinate thus produced is dried on a porous plate, and this, dissolved in oil of turpentine, constitutes the lustre.

—E. E. B.

Refractory Clays from Mähren. Hecht. Centralbl. f. Glasindustr. u. Keramik, 4, 212.

THE following samples of clays and argillaceous slates were obtained from Briesen in Mähren and were found to be abnormally refractory. They consisted of 99.7 to 93.7 per cent. of hydrated silicate of alumina, $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$; 0 to 2.8 per cent. of quartz, and 0.3 to 3.5 per cent. of felspar. They were markedly basic in character and their compositions were:—

—	a.	b.	c.	d.	e.
SiO_2	45.61	44.87	43.48	46.13	73.42

Preparation of Lustrous Metallic Surfaces on Glass and Glazed Ceramic Ware. S. Reich and Co. Deutsche Töpfer- u. Ziegler-Zeit. 20, 330.

AN aqueous solution of silver nitrate is mixed with a paste which when heated in a muffle at a low temperature will not fuse to the glass or porcelain, but can be readily detached from it. Suitable pastes may be made from chalk, earth, lamp-black, sulphur, madder lake, manganese dioxide, and oxide of iron. During the heating in the muffle the silver passes from the paste to the surface of the glass or porcelain, the paste is then carefully removed and the article heated gently for a few minutes in a reducing atmosphere, preferably in carbonic oxide. An adherent lustrous metallic coating is produced which in transmitted light appears light yellow to dark green white, while the lustre varies in appearance from that of silver to greenish gold. Three parts of paste are used for one part of silver nitrate. Chloride or sulphide of silver may also be used, the former imparting a greenish and the latter a yellow colour like the nitrate.—E. E. B.

Application of Colours under Glazes. Thonwaaren Ind. 1889, 3, 155.

FOR specially valuable designs and painting, colours under glazes should be applied mixed with oil. This involves, however, a special treatment of the article to enable the painted parts to take the glaze subsequently. For ordinary ware the colour can be applied mixed with a little gum tragacanth, gum arabic, or even glycerol, so that the colour may adhere to the body of the article sufficiently firm to avoid being washed away when the glaze is applied.

—E. E. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Efflorescence of Salts from Clay. Thonind.-Zeit. 13, 422.

THE mould-like crust which is often found on red bricks after they are burnt is produced in the process of drying and is due to the efflorescence of sulphate of lime or sulphate of magnesia. The efflorescence in the form of wart-shaped crystals can only be noticed on the unburnt bricks by means of a lens, and consequently usually escape detection at this stage.

Even in continuous kilns in which the fuel gases are more completely cooled than in the other systems the efflorescence takes place. The steam, sulphurous acid, sulphuric acid, and ammonium sulphate—when coal is used as fuel—play upon the surface of the bricks and form compounds which creep to the surface. The defect can only be remedied by carefully maintaining the temperature of each freshly charged chamber at 40° – 60° C.—E. E. B.

X.—METALLURGY.

Progress of Metallurgical Science in the West. R. Pearce. Eng. and Min. J. 48, 268–269.

THE author describes the process of copper smelting as carried out at the Argo works, and mentions that in former years, before care was taken in the assortment of ores, it frequently happened that the first matte contained a large quantity of lead in place of iron. An analysis of such a matte is as follows:—

	Per Cent.
Copper	32.03
Lead	26.60
Iron	9.50
Zinc	4.29
Silver	1.92
Gold	0.05
Sulphur	21.70
Insoluble residue, &c.	3.58
	<u>99.67</u>

Two analyses are given, showing the difference in composition of the upper and lower portions of a large tap of about seven tons of this matte. The former was of a very close texture, while the latter was crystalline and vesicular, the section of the mass being about 12 in.

	Upper Portion.	Lower Portion.
	Per Cent.	Per Cent.
Copper	38.6	31.0
Lead	18.9	37.1
	Oz. per Ton.	Oz. per Ton.
Silver	543	760
Gold	8.4	13

The objection to a matte so rich in lead lies in the fact that a still richer and a more fusible compound is formed which works its way into the hearth of the furnace. It is found in crystalline plates, and corresponds closely to the formula $5\text{Cu}_2\text{S} + 4\text{PbS} + \text{Fe}_2\text{S}_3$, and contains 2.5 per cent. of silver. At present the amount of lead in the first matte is nearly always under 10 per cent.

The first matte is worked into white metal containing 700 to 800 oz. of silver per ton, 10 oz. of gold, and 60 per cent. of copper, which metal is then treated for silver. It is crushed and passed through a six-mesh sieve, roasted for 24 hours, then ground fine and passed through a 60-mesh sieve, and again roasted to convert the silver into sulphate for extraction by the Ziervogel process. The presence of foreign metals interferes with the working of this process. Thus, arsenic, antimony and bismuth form insoluble compounds with silver, in consequence of which the quantity of the latter in the residues is increased. The residues from a fairly good matte contain about 40 oz. of silver, 10 oz. of gold per ton, and 55 per cent. of copper as oxide. They are worked up with pyrites into a rich matte, which is then

partly worked with the production of bottoms containing the gold and silver. The following is an analysis of bottoms:—

	Per Cent.
Copper	60.04
Lead	33.61
Arsenic	0.44
Bismuth	0.40
Iron	0.08
Zinc	0.15
Gold	0.54
Silver	1.35
Sulphur	1.68
	<u>98.29</u>

The power of the copper bottoms to remove the gold and silver from the matte is increased by the presence of the above impurities.

The silver which is obtained by precipitation with copper after the Ziervogel treatment generally contains an amount of cuprous oxide, together with some small scales of copper. These are removed by prolonged boiling with water containing a little sulphuric acid, into which air is injected by a small steam jet, after which the silver is melted into bars of an average fineness of 999.

The author states that at Montana the calciners are being replaced with great success, owing to the expense of labour and fuel, by capacious revolving cylinders, and again, from the long period the process of Bessemerising copper mattes has been in use, he believes its success is assured.—A. W.

The Manufacture of Aluminium from Cryolite. P. P. Bedson. British Association, Section B., Newcastle Meeting, 1889.

AFTER enumerating the principles of the various methods of obtaining aluminium the author proceeds to describe Netto's process as carried out by the Alliance Aluminium Company at Wallsend. On the large scale 200 lb. of cryolite are melted with the same weight of salt in a reverberatory furnace. When the fusion is complete, which is in about an hour and a half, the molten mass is run into a previously warmed iron converter, where it is subjected to the action of 40 lb. of sodium. The latter is added and allowed to act in portions of 5 lb. at a time, and each portion as it is introduced is forced under the surface of the fused material by means of a "dipper," consisting essentially of a slightly concave circular sheet of iron studded with holes. The first dipping is attended with violent action and the production of white fumes consisting chiefly of sodium fluoride, which, however, decrease as the further additions of sodium are made. When the operation is complete the bulk of the slag is poured off, and the last portion together with the aluminium is run into an iron vessel. The separation of the bulk of the slag in this way is essential, as otherwise the aluminium would redissolve in the slag during cooling. With a pure cryolite about 10 lb. of practically pure aluminium would be obtained from this charge, and the slags produced would contain:—

	Per Cent.
Sodium fluoride	about 40
" chloride	43
Cryolite	15
Metallic aluminium	0.75

A difficulty attending the use of cryolite is the presence of impurities, which vary in amount from 1 to 3 per cent., and consist chiefly of iron and silicon compounds. Advantage, however, is taken of the fact that these compounds are reduced by the sodium before the cryolite. With this view the dipping operation is divided into two, one-third of the sodium being used in the first and the remainder in the second, with the result that a metal containing 98 to 99 per cent. of aluminium is obtained from the second operation. The best quality of aluminium is obtained by "double dipping" in clay crucibles instead of in the iron converter. The metal obtained by "single dipping" averages from 95 to 97 per cent., while first metal from the "double dipping" process contains from 90 to 95 per cent. of aluminium.

An important factor in this manufacture is the regeneration of cryolite from the sodium fluoride of the slag by heating the latter with aluminium sulphate (this Journal, 1889, 713). Previous to this operation the 0.75 per cent. of aluminium in the slag may be removed as aluminium bronze by melting with metallic copper.

The sodium is manufactured by pouring fused caustic soda in a regulated stream over heated charcoal, the arrangement and apparatus being such that the carbonate of soda which is formed, together with the undecomposed caustic, drains from the charcoal into the bottom of the retort, whence it is removed. By this means the decomposition takes place at a lower temperature, which enables cast-iron retorts to be used instead of those of steel or wrought iron. The mixed carbonate and caustic is known as soda slag, and is sold to paper manufacturers and others, or may be recausticised. The following are the amounts of the materials necessary for the production of one part by weight of sodium:—

10 parts of caustic soda.
1.2 " cast iron for the retorts.
12 " coke.
1.5 " charcoal for reduction.

This quantity produces nine parts of soda slag containing about 60 per cent. of Na_2O .—A. W.

The Robert-Bessemer Steel Process. F. L. Garrison. Iron and Steel Institute, Paris meeting.

THIS paper contains a description of and some results obtained with the Robert modification of the Bessemer converter. This modification differs from the ordinary converter in having one side flat, while the tuyeres pass horizontally through this side some distance from the base. The tuyeres are likewise arranged obliquely to the central vertical axis, so that when the apparatus is at work the blast enters the metal obliquely and only a few inches below its surface, with the result that a rotary motion is given to the bath. The average pressure of the blast is about 4 lb., and the height of metal above the tuyeres only from 10 to 15 centimetres. The blow is conducted in three successive stages of tilting; the first stage lasts from seven to eight minutes, and is carried on with only a small height of metal above the tuyeres; the second stage, with the tuyeres deeper, lasts three to four minutes, and the final about two minutes. Ferro-manganese is then added. The converters are small, not exceeding three tons in capacity.

General analyses are given of the metals used and produced both by the acid and basic treatments; there are also tables showing the mechanical tests of some samples of metal produced by this process, but only average analyses are given with the latter.

The author, in his concluding remarks, states that the idea of raised tuyeres is not new, though when Bessemer blew air into the metal near the surface he obtained an abnormal amount of slag and brown smoke with a large loss of iron. The loss of iron in the present instance is stated by the inventor to be only about 12 per cent. under normal conditions, and from 13 to 18 per cent. with a basic lining. Finally, the author finds it difficult to believe that a complete and uniform circulation of a bath of such a heavy metal can be maintained with only 4 lb. of blast, though he has seen most excellent material produced in this converter.

—A. W.

On the Influence of Sulphur in Zinc Smelting. A. Voigt. Zeits. f. angew. Chem. 1889, 571—573.

IN calculating the waste which occurs in zinc smelting, sulphur is accredited with playing an important part. Now it is true that excessive loss of zinc occurs when furnace products, roasted blends, and ores poor in zinc, are employed, but the assertion that the presence of sulphur is the cause of this is not based on experiment. B. Kerl states ("Grundriss der Metallhüttenkunde," 1881, 436) that one atom of sulphur (= 32) holds back one atom of zinc (= 65), and that the sulphur in the roasted material is present as sulphide or sulphate. The author has also detected the presence of traces of free sulphur. Now the sulphates present in roasted blends mainly consist of calcium sulphate and a little lead sulphate, only traces of zinc sulphate being found. The roasted material contains on an average 7 per cent. of sulphur, of this 0.5 to 1.3 is present as sulphide; the rest as sulphate. Now this could account for a loss of about 14 per cent. of zinc which ought, however, to be found in the residual ash of the smelting as zinc sulphide. This is, however, not the case, for on extracting these residues with caustic alkali it is found that most of the zinc is present as oxide, only a very small portion being present as sulphide. The rest of the sulphur found is present as calcium and iron sulphides.

The author has carried out a number of analyses on average monthly samples of the residues from the smelting of blends and blast-furnace products, especially determining:—

A. The total amount of zinc.

- (1.) Zinc present as oxide (extracted by means of soda lye).
- (2.) Zinc present as sulphide (by difference).

B. Total amount of sulphur.

- (1.) Sulphides soluble in concentrated acetic acid.
- (2.) Sulphides soluble in hydrochloric acid.
- (3.) Sulphur present as sulphates (determined in only one or two cases).

No. of Sample.	Total Zinc.	Zinc extracted by NaOH.	Difference.	Total Sulphur.	Soluble in Acetic Acid.	Difference.	Sulphur present as Sulphates.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
I.	3.66	2.4	1.26	3.91	0.91	3.00	..
II.	3.33	2.10	1.23	4.52	0.21
III.	3.12	1.99	1.13	4.49
IV.	4.17	2.86	1.31	3.88	0.86	2.87	0.15
V.	5.33	3.21	2.12	3.41	0.79	2.62	..
VI.	5.20	3.75	1.45	3.67	0.77	2.90	..

In II. and III. the sulphur compounds soluble in acetic acid were not determined as the residues to be tested had been contaminated.

The results it will be seen do not bear out the contention that one atom of sulphur holds back one atom of zinc. Most of the sulphur seems to be combined with iron (and possibly with manganese) and with calcium. It cannot be asserted that the sulphur in the blends is particularly harmful, for the analyses of a residue from the smelting of

a calamine containing 1.09 per cent. (but not as zinc sulphide), with a reduction cinder containing 1.23 per cent. of sulphur, gave the following results: 2.50 per cent. of zinc, of which 1.98 per cent. was present as oxide and 0.52 per cent. as sulphide; 2.65 per cent. of sulphur, 0.86 per cent. of which was present as calcium sulphide. These results do not differ much from those obtained above. There is no reason therefore to look upon the sulphur in the blends as exerting a specially harmful influence.

Many calamines contain more or less gypsum and traces of zinc sulphide (Schwefelkies), e.g., calamine samples contained 0.52—0.91—4.7 per cent. of sulphur.

The blast-furnace products, too, contain from 1.5 to 3.0 per cent. of sulphur when they are used for smelting purposes, e.g., samples of the latter contain 1.9—2.5—1.55—2.97 per cent. of sulphur.

Finally the reduction cinder contains sulphur, e.g., 1.21—0.98—1.15 per cent.

Blende is more difficult to smelt than calamine, but this can be due to other causes than the fact that it contains more sulphur.

Temperature no doubt plays an important part, and it therefore seems important to take into account what influence the acidity or basicity of the minerals present exerts on the reduction of the temperature at which they melt and form a good slag. Further, the author adduces evidence to show that the reduction cinders from different sources cause a greater or less loss when employed with the same material, so that it would be useful to carry out investigations on the quantitative effect of cinders.

—F. W. T. K.

Fusing Point of Blast-Furnace Slags. P. Gredt. Stahl. u. Eisen. 1889, 9.

THE results of these experiments are of importance for both the iron and pottery industries. For the economical working of a blast furnace the melting point of the slags which are formed is of consequence, as these ought to melt in the furnace at the same temperature as the iron. If they melt at a lower temperature they will combine with some of the iron, and if at a higher temperature a waste of fuel takes place. The formation of a suitable slag must therefore be carefully regulated by the addition of various gangues and fluxes in definite proportions. The slags obtained from a blast furnace in good working order consist almost entirely of silica, alumina, lime and magnesia, together with small quantities of alkalis and iron.

The author obtained the requisite materials as pure as possible, and made them up with pure dextrin into tetrahedra resembling Seger's cones. Two series of slags were prepared in this manner:—In Series I. the amount of silica was kept constant and the proportions of lime and alumina varied from no lime to no alumina, whilst in Series II. the cone with the lowest melting point in Series I. (No. 11) was taken as the basis and the lime in it gradually replaced by magnesia. In this manner the temperature of formation of slags containing silica, lime, magnesia and alumina in every proportion was ascertained. From such experimental data a slag can be compounded to melt at any desired temperature.

—E. E. B.

PATENTS.

Improvements in the Hardening and Tempering of Steel. H. W. Wallis, London. Eng. Pat. 14,332, October 5, 1888. 4d.

INSTEAD of using a bath of oil or water, &c., the patentee employs a bath of sodium or potassium, or an alloy of sodium and potassium. The sodium or potassium, or the alloy, is melted and heated to the temperature which is most suitable to the degree of temper or hardness to be given to the articles.—T. L. B.

Improvements in the Dipping Process for Depositing Metals upon Iron and Steel. A. Lévy, Paris, France. Eng. Pat. 15,698, October 31, 1888. 6d.

FOR *bronzing*, an ammoniacal solution of any salt of copper is poured into a clear solution of a tin salt containing a mineral or organic acid. The clear solution obtained constitutes the *bronzing bath*. It is used cold, and gives a deposit very adherent, sufficiently thick, and not spoiling in any way the polish of the object it covers.

A good yellow bronze may also be obtained by first tinning the objects in a boiling solution of salt of tin

containing oxalic acid, and then placing them "in a red copper bath of ordinary composition," but rather poor in copper.

Before *gilding* and *silvering* it is necessary to coat the objects with copper as described; they may then be dipped in well-known gilding or silvering baths. The same results may be obtained by previously nickeling instead of coppering.

Nickeling is carried out by first coppering or tinning, as above described, and then placing in a bath of simple or complex nickel salt, and more especially of chloride of nickel, to which is added sal-ammoniac and sea salt. The higher the temperature of the nickel bath the better and more rapid are the results; at the boil less than a minute is necessary to obtain a sufficiently thick deposit of nickel.

Besides the process itself the invention consists of the general method dependent upon the contact of two metals, iron and copper, or iron and tin, for example, which contact serves to effect, without the aid of an external current, the deposit of a third metal—not a substitution of a third for one of the others. Thus *gilding* and *silvering* may be effected by nickeling and then dipping in the gilding and silvering baths.

Deposits of *cobalt* and *aluminium* may be obtained in exactly the same way as nickeling is performed. Eight claims are made.—T. L. B.

Improvement in the Treatment of Quartzose or Siliceous and Sulphuretted Ores containing Gold, Silver, or Copper. H. B. Fulton, Kirkintilloch. Eng. Pat. 16,499, November 14, 1888. 8d.

INSTEAD of treating the ores in two operations, first calcining them and then melting with fluxes, the whole process is performed in one operation, and after it has been commenced the use of fuel is entirely dispensed with. The ores must be added in the proportions necessary to effect (1) combustion; (2) the formation of a metallic regulus; and (3) the formation of a fusible slag. The smelting is performed in a blast furnace preferably closed at the top, fuel being used at first to raise it to the required temperature before adding the charge, which must contain sufficient sulphide to render the addition of more fuel unnecessary. Superheated air is used for the blast.—E. E. B.

An Improved Method of Coating Iron or Steel Plates with Copper and other Comparatively Non-oxidisable Metals. G. Prout and D. Murray, London. Eng. Pat. 17,269, November 27, 1888. 4d.

THE iron or steel plate is heated to a temperature of 2,000° F. or thereabouts, and the surface then sprinkled with borax, rosin, or other suitable flux; the requisite quantity of copper in the molten state is then brought on to the plate, which is then passed between rolls heated to a temperature somewhat below the melting point of the coating metal. The rolling is continued until the coating metal undergoes solidification. Any suitable furnace may be employed for heating the plates or for melting the copper; the rolls may be heated by means of a gas flame. Other metals of a comparatively non-oxidisable character, and adapted for being rolled, may be welded in a similar manner to an iron or steel back, the flux and temperature being suitably varied according to the object to be accomplished.—T. L. B.

An Improved Mode and Manner of Preparing Materials for carrying out the Operations of Smelting and the like. R. Middleton, Leeds. Eng. Pat. 17,373, November 29, 1888. 6d.

THE invention consists in using up (1) small fuel, such as coke and coal dust; (2) small, or dust-like ores; (3) small, or dust-like fluxes; and (4) in thoroughly intermixing among the various particles such other useful materials as may be desired. The material having been brought to a suitable size and condition for passing through compressing machinery is then mixed in the following proportions, say, ore, 48 per cent.; enriching ore, or other agent, 8 per cent.,

fluxing agent, 13 per cent.; fuel, 25 per cent.; pitch, 6 per cent.; the proportions varying according to the nature of the ore, the quality of the materials, the temperature and volume of the blast, and the purpose for which the metal is required. The compound is now made into blocks by compression under a pressure of not less than two tons per square inch, and then stacked.—E. S.

Improvements relating to the Treatment of Nickel and Cobalt. H. H. Lake, London. From P. Manhes, Lyons, France. Eng. Pat. 17,406, November 29, 1888. 6d.

THE impure nickel or cobalt is cast into any suitable form, preferably that of very thin plates, and then heated until the surface of the metal is oxidised. Upon melting the partially-oxidised metal with suitable fluxes metallic nickel or cobalt is obtained, the oxygen combining with the other metals to form oxides which are absorbed by the flux.

—E. E. B.

Improved Method of Extracting Nickel and Cobalt from Ores or Compounds and Apparatus therefor. H. H. Lake, London. From P. Manhes, Lyons, France. Eng. Pat. 17,410, November 29, 1888. 8d.

THE ores are melted and the liquid matte or crude metal poured into a converter previously heated to redness. This is placed in a vertical position and air blown in from the bottom. The combustion of the impurities in the ore causes great elevation of temperature, which is kept up by throwing coke on to the fused mass. As the temperature tends to get lower the converter is inclined so as to allow the air to enter at a higher level. Drawings are given of a converter which will allow the air to enter at any desired height. The metal obtained by the process requires to be purified. (See Eng. Pat. 17,406 of 1888, preceding abstract.)—E. E. B.

Improvements in Methods of and Apparatus for Separating Ores or Metals from Associated Gangue. B. J. B. Mills, London. From T. A. Edison, Llewellyn Park, U.S.A. Eng. Pat. 17,614, December 3, 1888. 8d.

THE finely pulverised ore is made to fall from a hopper, through slots or holes in its base, in fine streams and in its descent is subjected to the action of a gentle air current and a magnet placed at the side of the falling material. The ore falls into an apparatus consisting of various compartments so arranged that the lighter particles are blown into one compartment, and the magnetic particles of ore, being altered in their line of fall by the magnet, fall into another. Non-magnetic iron ores are made magnetic by heating to a white heat, or by partial reduction with carbon monoxide. To separate gold from its ores by this apparatus, the finely powdered ore is subjected to the action of a solution of an iron salt with the electric current, whereby the gold particles become coated with iron, which renders them magnetic. The ore is then dried and submitted to the action of the magnetic separator. Drawings of the apparatus are given.

—A. W.

Improvements in the Method of and Apparatus for Effecting the Separation of Iron or Iron Ores by Mechanical Means from Associated Gangue. B. J. B. Mills, London. From T. A. Edison, Llewellyn Park, U.S.A. Eng. Pat. 17,614A, December 3, 1888. 6d.

LOLITHIC iron ores cannot be concentrated by the magnetic separator of the previous patent (Eng. Pat. 17,614), because when the material is heated to render it magnetic the gangue hardens and cakes on the tablets of richer ore. The separation is effected by crushing the ore through rollers, cleaning the tablets by revolving them in a cylinder with lumps of a harder substance, such as quartz, and passing the mixture through a revolving inclined cylindrical screen of a given fineness. The rich tablets, being of about one size and larger than the particles of gangue, are thus separated from the latter.—A. W.

Improvements in the Method of and Apparatus for Extracting Gold from its Ore by Amalgamation. B. J. B. Mills, London. From T. A. Edison, Llewellyn Park, U.S.A. Eng. Pat. 17,614B, December 3, 1888. 6d.

TO recover the gold from low grade sulphide ores the material is pulverised, concentrated by "vamping," and then treated with weak nitric acid preferably mixed with a little nitrate of mercury. By this means the fine particles of gold which would not previously amalgamate become cleaned and coated with a layer of mercury. The liquor is drawn off, the ore either dried by centrifugal action or washed with water, and the gold then extracted by any convenient amalgamation process.—A. W.

Improvements in the Application of Sulphide of Silver to Metallic Surfaces, applicable to Jewellery and the like. E. A. Billant, Paris, France. Eng. Pat. 17,786, December 5, 1888. 4d.

THE metallic article is placed in a mould into which molten sulphide of silver is then poured, and by this means a firmly adherent coating of silver sulphide is obtained. The whole operation is performed in a reducing atmosphere.—E. E. B.

Improvements in the Preparation and Treatment of Bromine for the Extraction of Gold from Ore or for other Purposes. M. H. Simpson, London. Eng. Pat. 17,930, December 7, 1888. 6d.

THE invention refers more especially to the use of bromine for the extraction of gold in the wet way from materials such as pyrites, tailings obtained in ordinary gold-washing processes, and the like. An alkali, caustic soda by preference, is saturated with bromine forming a hypobromate; this on evaporation forms a powdery material which can be readily transported. Acid sodium sulphate is also prepared. The material to be treated is placed in barrels, moistened with hypobromate solution, and the acid sulphate solution added in proper quantity. Bromine is thus liberated, which then acts on the gold. If necessary a carbonate can be added, and the solvent action of the bromine on the gold increased by the pressure set up from the formation of carbon dioxide.

—S. G. R.

An Improved Method of Coating Iron or Steel with Copper and other Comparatively Non-oxidisable Metals. G. Prout and D. Murray, London. Eng. Pat. 18,218, December 13, 1888. 6d.

TREATS of the coating or facing of iron or steel rods, tubes, castings, forgings and other bodies.

Iron bars are heated to a temperature of about 2,000° F. and sprinkled with borax, rosin, or other suitable flux. They are then plunged into, or passed through, a bath of molten copper or other coating metal, after which they are rolled between heated rolls, as in Eng. Pat. 17,269 of 1888 (see page 987), or in some equivalent apparatus until the coating has solidified, and a smooth finished surface has been obtained. Iron or steel rods, tubes and similar products may be coated in a like manner. Bodies of irregular form such as castings may be coated by heating, as above, sprinkling the surface with flux, and then plunging into a bath of the molten coating metal. Certain of these objects may then be subjected to the action of a press. In coating iron or steel rolls a mould may be made and the roll, heated as before, introduced as a core; the surrounding space is then filled with the coating metal. In lining cylinders, the cylinder is heated, a core introduced and the intervening space filled with the lining metal. The internal surfaces of tubes may be coated by rotating the heated tube, which is at an inclination, and running the molten metal through it. For coating internal surfaces in general the vessels are heated to the necessary temperature and a sufficiency of molten metal is introduced.—T. L. B.

Improvements in Cleaning Tin, Terne, or other Metal Plates, and Apparatus therefor. T. Summers, Gloucester. Eng. Pat. 18,632, December 20, 1888. 8d.

HITHERTO the process of cleaning tin-plate, &c., after tinning, has been carried out by hand. The present invention accomplishes the operation by mechanical means and so permits of hand labour at this stage of the manufacture being dispensed with. The machine consists of two casings each enclosing a pair of vertical revolving shafts; the shafts carry a number of radial wings or vanes, and a central slot is cut in each side of each casing for the ingress and egress of the plate to be cleaned. The casings are filled with bran or equivalent material, and this is agitated by the vanes carried by the revolving shafts. The tin-plate to be cleaned is pushed through the first slot and between the first pair of revolving shafts and is then carried forward, and at the same time cleaned by the action of the bran. Upon leaving the first casing it enters and passes through the second casing, where it undergoes still further cleaning. If friction rollers be used the passage of the plate can be more easily regulated, and it may also be made to travel in the opposite direction to the particles of bran, the cleaning action being intensified thereby. For conducting the plate from the tinning bath to the cleaner a reciprocating carrier is employed worked by a cam, crank or eccentric mounted in the machine. Bran forced from the machine is picked up by elevators and returned to the proper casing. Four drawings are given.

—T. L. B.

Improvements in Apparatus for Use in Decomposing Chemical Compounds, Metallic Salts, and Desulphurising Ores. P. H. Adams and O. T. X. Adams, Chicago, U.S.A. Eng. Pat. 10,991, July 8, 1889. 8d.

Improvements in Apparatus for Use in Decomposing Chemical Compounds, Metallic Salts, and Desulphurising Ores. P. H. Adams, and O. T. X. Adams, Chicago, U.S.A. Eng. Pat. 11,020, July 9, 1889. 8d.

THE object of the patentees is the construction of an improved apparatus for mechanically decomposing chemical compounds and metallic salts, and desulphurising ores or their resulting material, by the action of centrifugal force, when the substances are in a molten condition. (See also following abstract.)—E. S.

Improvements relating to Apparatus for Smelting and otherwise Treating Ores. P. H. Adams and O. T. X. Adams, Chicago, U.S.A. Eng. Pat. 11,021, July 9, 1889. 8d.

THIS patent relates to the process of subjecting molten furnace products to the action of centrifugal force. Drawings of the plant are given from which the essential point appears to be to place the centrifugal machines at a lower level than and near to the furnaces so that the fused materials may be run direct from one to the other through covered conduits.

—A. W.

Improvements relating to the Treatment of Ores containing Lead, Zinc, and other Metals. F. L. Bartlett, Portland, U.S.A. Eng. Pat. 12,322, August 2, 1889. 6d.

COMPLEX ores containing sulphides of zinc, lead, copper, silver, &c., are mixed with an excess of sulphur in the form of iron sulphide, and then with two-thirds by weight of a flaming fuel such as petroleum or bituminous coal. The whole is then burnt on a shallow hearth. The zinc and lead are given off in the form of fume, while the other metals remain behind with part of the sulphur. It is maintained that by thus having an excess of sulphur present the zinc in volatilising does not carry with it any silver, and further that the non-volatile metals are entirely freed from zinc. Again, no sulphuric acid is formed, as it "is destroyed by the action of the hydrocarbon flame and the air which is admitted for this purpose."—A. W.

Improvements in Extracting Metals from Alkaline Solution, Scrap, or Waste Materials. N. M. E. Tenison-Woods, London. Eng. Pat. 13,013, August 17, 1889. 4d.

STRONG alkaline "solutions of oxides of tin and other metals soluble in an alkaline medium, such as zinc, cadmium, lead, and tungsten" are placed in iron vessels (any lead present in the form of plumbate being first removed by the addition of an alkaline sulphate). An iron cage containing scrap zinc, preferably in the form of pieces of refuse galvanised iron from old pails, roofing, &c., is immersed in the liquid which is heated to nearly 100° C. Electric communication is then made between the side of the iron vessel and the zinc in the cage. Nascent hydrogen is liberated on the inner side of the vessel with separation of metallic tin whilst zinc is dissolved from the scraps, leaving metallic iron in a saleable form if galvanised iron has been employed. The zinc is recovered from the solution by passing carbonic acid through it, when bicarbonate of zinc is precipitated. The solution is then re-causticised and used over again.—E. E. B.

Method or Process for obtaining Aluminium. H. J. Allison, London. From "The Great Western Aluminium Smelting and Refining Co.," Denver, U.S.A. Eng. Pat. 13,839, September 3, 1889. 4d.

THE principle of this patent is to act on the aluminium compound with a substance whose elements readily dissociate, yielding one element which has a greater affinity for the element with which the aluminium is combined than the aluminium itself has, liberating also another element which has no affinity for aluminium. Thus fluoride of aluminium or cryolite is fused and acted on in a crucible or other suitable appliance with the sulphide, hydride, "carbohydride," or nitride of silicon or boron, whereby any of these latter compounds dissociate, the silicon or boron combining with the fluorine and releasing metallic aluminium. Alloys can be produced by performing the operation on the surface of the molten metal with which it is desired to alloy the aluminium.

—A. W.

Improvements in and Apparatus for the Manufacture of Soft Back Steel. M. A. Howell, jun., London. Eng. Pat. 14,473, September 13, 1889. 4d.

THE invention relates to the manufacture of plates or flat bars of steel, having one side highly carbonised, and the opposite side practically free from carbon. Such steel is less liable to break or crack while hardening and is more tenacious when in use where great rotary force or heavy blows or strains are required.

Plates or flat bars of soft steel or fine iron in pairs of equal size are placed back to back with a film of clay or other refractory material interlaid between them. They are then clamped or wired together and the several pairs placed "in a receptacle or flask stratified between layers of granulated charcoal." The flask, furnished at one end with an inlet tube and cock, and at the other end with an outlet cock, is placed horizontally in a muffle. When the heat of the furnace has raised the temperature of the flask to a low red heat a current of hydrocarbon vapour is driven over the plates, and when the heat reaches the cherry-red stage the flow of the gas is diminished and the operation continued until the metal has taken up enough carbon.

Finally the cocks are closed, the flask disconnected and allowed to cool in an atmosphere of hydrocarbon. When cool the receptacle is opened and the plates are taken out and forged, hardened and tempered in the usual way.

—T. L. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Occlusion of Gas in the Electrolysis of Copper Sulphate.
A. Soret. *Compt. Rend.* **108**, 1298—1300.

THE author concludes that electrolytic copper contains only two occluded gases, hydrogen and carbon dioxide, that the former is most abundant, often five-sixths of the whole, especially when the electrolyte is acid; and that when the deposit is not tenacious, it is due to excess of carbon dioxide, which may amount to nine-tenths of the occluded gases when the bath is neutral.—J. M. H. M.

Note on the Development of Voltaic Electricity by Atmospheric Oxidation of Combustible Gases and other Substances. C. R. A. Wright and C. Thompson. *Proc. Roy. Soc.* **46**, 372—376.

THE battery described by Mond and Langer (this Journal, 1889, 550), consisting of a number of plates of porous material coated with platinum black and impregnated with dilute sulphuric acid, and fed with hydrogen and air, though improved in design, is substantially identical in principle with the batteries previously described by Wright and Thompson (*Proc. Roy. Soc.* **44**, 182). The conclusions then arrived at as to the practicability of a battery of the form shown in the figure, consisting of a number of prepared

plates arranged so as to form a series of chambers alternately closed in and filled with hydrogen and open to the air, the connexions being made as indicated, were—(1.) Various causes, such as leakage of gases from one chamber to another, prevented the electromotive force of a battery of n doubly-coated plates from reaching quite as high as n times that obtainable from a single cell. In no case was an electromotive force as high as one volt per cell obtained, even when the currents were very small. With currents of magnitude sufficient to be measured readily with a silver voltammeter, the highest value was only 0.6 to 0.7 volt per cell. (2.) Nevertheless the results were sufficiently encouraging to show that if expense of construction were of no object, then, by employing large plates, currents comparable with those derived from ordinary small primary batteries could be readily produced. (3.) The economical production of powerful currents by the direct oxidation of combustible gases is questionable, chiefly on account of the first cost of the appliances necessary. Generally the same remark applies to all other forms of cell in which oxidation is effected by means of an "aeration plate," whether the energy be due either to the oxidation of a metal (like zinc or aluminium) or to the oxidation of fluids, such as a solution of Schützenberger's sodium hydrosulphite or ammoniacal cuprous oxide. Although they have not yet succeeded in effecting in this way the oxidation of alcohol, petroleum, coal, and such like forms of comparatively cheap sources of energy, yet they do not regard such actions as impracticable.

In the paper "On a New Form of Gas Battery," by Mond and Langer (read before the Royal Society, June 20th, 1889),

experimental results are given which corroborate the previous work of Wright. (See *Proc. Phys. Soc.* **4**, 101; *Phil. Mag.* **77**, 169.)—W. W. H. G.

PATENTS.

Improvements relating to the Separation of Lead from Silver and from other Substances associated therewith. A. Arche, Vienna, Austria. Eng. Pat., 16,821, November 19, 1888. 4d.

CRUDE lead cast into any suitable form, preferably that of very thin plates, is placed in a bath containing lead nitrate (1.5 per cent.) and nitric acid (5 per cent.). An electric current is then passed through the bath, when pure lead is deposited in the form of crystals on the positive electrodes, whilst the silver and other metals are deposited as a black slime on the negative electrodes.—E. E. B.

Improvements in the Manufacture of Chlorine. T. Parke and A. E. Robinson, Wolverhampton. Eng. Pat. 17,367 November 29, 1888. 4d.

See under VII., page 983.

Improvements in the Extraction of Metals from Ores and Slags, and the Débris from Smelting Works and other Manufacturing Works. J. Shears, London. Eng. Pat. 9821, June 14, 1889. 4d.

REFUSE tin slags are finely powdered and fused with caustic alkali. After treating the melt with boiling water, the clear solution, containing alkaline stannate, silicate and tungstate is heated in an iron vessel. On passing an electric current through it, pure metallic tin is deposited on the sides of the iron vessel.—E. E. B.

Improved Composition adapted to Electric Insulators and other Articles and Uses in the Arts and Manufactures. F. Marquard, New York, U.S.A. Eng. Pat. 12,046, July 30, 1889. 6d.

See under XIII., page 992.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On the Testing of Machine Lubricating Oils. O. Bach. *Chem. Zeit.* **13**, 905—906.

THE present methods of testing the gumming or oxidation of above oils take a long time (several days) by the usual processes.

The author uses the process of Fresenius (*Chem. Zeit.* **4**, 238), with slight modifications.

The oil is heated for 10 hours with oxygen in a sealed tube (about 100 to 125 cc. capacity) in an air-bath; the point of the tube is then broken under a measured volume of water, and from the difference in volume the absorption is calculated. The presence of excess of oxygen after the experiment should be proved with a glowing splinter of wood.

The author gives, amongst others, the following absorptions, 1 grm. of oil being taken in each case:—

	Oxygen Absorbed, cc.
Mineral oils	0.1 to 0.7
" (0.865)	4.8
Lubricating grease	21.8
Cod oil (0.963)	76.3
Roast oil	181.0
Olive oil	144.0
Rape oil	166.0
Cotton-seed oil	111.0
Mineral oil (0.865) with 10 per cent. of cod oil ..	9.4
Oleo-naphtha " " ..	8.6

The admixture of rosin oil or vegetable oils to mineral oils can thus be detected on account of the low oxygen absorption of the latter. Further, the oxygenated oil has only a slight or no acid reaction in the case of mineral oil and a strongly acid reaction in that of rosin oil.—D. A. S.

PATENTS.

Improvements in the Means and Apparatus for Extracting Fat and other Soluble Substances from Materials containing them. M. Bauer, London. From J. Merz, Farnov, Austria. Eng. Pat. 9352, August 5, 1885. Amended July 24, 1889. 8d.

THE emendations are concerned in a clearer description of the invention. (Compare title of original specification, this Journal, 1886, 432.)—O. H.

An Improved Manufacture of Oleaginous Material from Hydrocarbons, applicable for Saponification and other Purposes. H. R. von Dahmen, Vienna, Austria. Eng. Pat. 14,692, October 12, 1888. 4d.

HYDROCARBONS, such as heavy mineral oils, are mixed with from 15 to 25 per cent. of "elain," or oleic acid, or other fatty acids; the mixture is then heated to 60° C., and subjected for half an hour to the action of sulphuretted hydrogen gas, after which it is neutralised with from 1 to 5 per cent. of calcined carbonate of soda; it is then ready for saponification by the usual methods.—W. L. C.

An Improved Process and Composition for extracting Oil from and cleaning Cotton Waste. W. Michell and S. Picard, London. Eng. Pat. 17,628, December 3, 1888. 6d.

THE waste is subjected to hydraulic pressure to extract most of the oil, and then agitated in a bath of boiling water to which is added a solution containing caustic potash and soda, pearl ash, soda crystals, lime, ammonia, cyanide of potassium, borax, turpentine and "benzoline."—W. L. C.

Improved Antiseptic Washing and Cleansing Compounds. J. Ascoug, Handsworth. Eng. Pat. 18,260, December 20, 1888. 4d.

BORAX, a mixture of boracic acid and sodium carbonate, or some other boron compound, is either sprinkled into melted paraffin wax or similar substance, or, if the smell of such be objectionable, the boron compound may be incorporated with any dry or granulated saponaceous compound.

—W. L. C.

Improvements in Apparatus to be Employed in the Manufacture of Soap. G. T. Bishop, London. Eng. Pat. 19,015, December 29, 1888. 6d.

A CYLINDRICAL vessel is heated underneath by a gas burner or otherwise, and within it are plungers carried by concentric or symmetrically arranged rods which alternately approach and recede from each other, for the purpose of thoroughly incorporating the contents. A drawing is given.—W. L. C.

Improvements in Washing Wool and in Treating and Utilising the Washings. H. W. Langbeck, Loughton. Eng. Pat. 66, January 2, 1889. 6d.

THE wool is twice soaked in warm water, not exceeding 110° F., then pressed and dried by centrifugal action. The solution thus obtained yields on evaporation impure potash salts, which may or may not be treated with mineral acids. The wool is then scoured with soap-lye to remove the whole of the fat and the remaining dirt. The emulsion thus obtained is concentrated and treated with dilute alcohol; by this means the soap is removed from the wool-fat and dirt. From the former the spirit is recovered by distillation, while the fat and dirt are separated from each other by a

solvent or by hot pressure. The preliminary soaking in water may be dispensed with, in which case the wool-washings are concentrated and treated with mineral acid, to liberate the fatty acids, or with salt to precipitate the soap and fat together.—W. L. C.

Process for Producing Hard Soap from Vegetable or Animal Fats, a Mixture thereof, and Caustic Alkaline Solutions, without employing Carbonate of Alkalis or Chloride of Sodium. H. Schuster, Leudsiel, Germany. Eng. Pat. 11,660, July 22, 1889. 4d.

A GIVEN weight of the fat to be saponified is mixed with an equal weight of a solution of pure caustic alkali, of not less specific gravity than 35° B. Slow "intermissive" heating is applied to this and the mass becomes spontaneously superheated. In a few hours complete saponification is effected.—W. L. C.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

Australian and Tasmanian Sandarach. J. H. Maiden. Proc. Roy. Soc. Tasmania, August 1889.

THE following is a list of resins of different species of Australian pines.

Resins of *Callitris cupressiformis* ("Oyster Bay pine" of Tasmania), *Callitris calcarata* ("Murray-," "Black-," "Red-," "Scrub-," "Cypress pine"), *Callitris columellaris* ("Cypress pine"), *Callitris verrucosa* ("Mountain Cypress pine"). All these resins have an excellent appearance as regards colour and brilliancy. They are almost completely soluble in rectified spirit, while light petroleum spirit dissolves a very considerable quantity. They possess a pleasant aromatic odour, similar to that emitted by ordinary sandarach. When the trees are wounded these resins exude in an almost colourless transparent condition and have a high refractive power. They soften slightly in boiling water and feel gritty to the teeth.—J. W. L.

Analyses of Black Wax for Polishing. F. M. Horn. Chem. Zeit. 13, 831.

THE author received from a Vienna cabinet-maker samples of soft and hard wax for analysis. These when dissolved in turpentine were used as polishes to invest any article with a brown (natural colour), hard, non-sticky, dull glassy surface. They gave on testing:—

	Soft Wax.	Hard Wax.
Melting point.....	68·2°	80·4°
Acid equivalent.....	0·0	0·6
Saponification equivalent	0·0	14·5

The melting point was taken by Pohl's method (Wiener Akademie, Ber. 6, 587). The soft wax was identified as crude cerasin. The high melting point and the above equivalents of the hard wax excluded beeswax, rosin (colophony), and Japan wax, while they pointed to Carnauba wax. Moreover, on heating, its characteristic odour was smelt. According to Valenta the average saponification equivalent of Carnauba wax is 94·8 and the acid equivalent 4·0. The percentage of Carnauba wax in the hard wax is therefore:—

$$\frac{13·9 \times 100}{94·8} = 14·7 \text{ per cent. and } \frac{0·6 \times 100}{4} = 15 \text{ per cent.}$$

or cerasin 85 per cent., Carnauba wax 15 per cent.—D. A. S.

PATENTS.

Improvements in the Manufacture of Material to be Used as a Substitute for Gutta-Percha, Rubber, or Oiled Tissues for Surgical Bandages, Sheeting, and other Purposes. H. A. Schlessinger, London. Eng. Pat. 13,917, September 27, 1888. 6d.

WHEN required for use as a surgical dressing the new material is prepared as follows:—paper made from long, pure, manilla fibre is saturated, in any convenient and expeditious way, with an emulsion of gelatin to which soap may be added. After the excess of the emulsion has been removed by pressure through rollers, the gelatin is fixed by immersion in a bath containing chrome alum, bichromate and an aluminous salt; it is then dried, and afterwards washed with water to remove the excess of the fixing salt. Glycerin either by itself, or as an emulsion with petroleum jelly and mixed, if desired, with an antiseptic, is then applied to the surface, the whole subjected to warmth and the excess of fatty matter removed; the result is a finished material valuable for the above purposes. A common variety, which may be used as a substitute for vegetable parchment, is produced by treating nuzised paper with an emulsion of rosin soap, fatty matter and glue, fixing, rinsing, and drying, as before—C. C. H.

Improvements in the Manufacture of India-Rubber Waterproof Garments. G. C. Mandleberg, H. L. Rothband, and S. L. Mandleberg, Manchester. Eng. Pat. 16,543, November 14, 1888. 8d.

THE india-rubber after dry kneading is soaked for 24 hours in deodorised petroleum naphtha at about "76 degrees of Baum's hydrometer," left in a closed vessel for other 24 hours, stirred occasionally, then passed through rollers, spread on the fabric at a temperature of about 80° F., and the product vulcanised.

The seams of the garments are cemented together by a solution of rubber in the solvent mentioned above, and the finished articles kept at 80° F. until they cease to smell. They may be scented with some volatile perfume.

Deodorised coal-tar naphtha may be substituted for the petroleum product, the chief requirement which either has to satisfy, being that of leaving no smell on evaporation.

An apparatus for preparing and preserving the cementing solution is illustrated and described. It consists of a vessel with an air-tight cap through which passes a vertical shaft furnished with blades for mixing the rubber and its solvent, which are introduced through suitable openings in the side, also covered by caps. By the use of this device waste of the solvent by evaporation is avoided.—B. B.

Improvements in the Manufacture of certain Classes of India-Rubber Goods. J. Caillet, Paris, France. Eng. Pat. 17,417, November 29, 1888. 4d.

INDIA-RUBBER goods of which the surface is exposed to mechanical wear are furnished with a protective coating of some intrinsically hard material such as emery. Taking the case of moulded goods as typical, the patentee coats the interior of the mould with glue or similar adhesive matter, then sprinkles ground emery upon the surface thus prepared, charges the mould with the preparation of india-rubber and vulcanises in the usual way; the heat incidental to the last process causes "the glue to be dissipated," and the article when withdrawn from the mould is found charged as to its exterior with particles of emery. Such a coating is also alleged to afford protection against the heat of the sun.

—B. B.

Improvements in the Preparation of Barytes for Use as a Pigment. M. Williams, Liverpool. Eng. Pat. 382, January 9, 1889. 4d.

BARium sulphate alone or mixed with chalk, pipeclay, alum, alumina, "oyster shell white" calcined bones, "Paris white," whiting, "lime oxides or other metallic substances," is dyed or stained with any suitable colouring matter in its

appropriate solvent; the latter may, if volatile, be recovered by distillation. The pigment thus obtained can be mixed with other pigments or paints to which it has been the custom to add uncoloured barium sulphate without causing the deterioration of their appearance which follows the use of the latter.—B. B.

Improved Composition adapted to Electric Insulators and other Articles and Uses in the Arts and Manufactures.

F. Marquard, New York, U.S.A. Eng. Pat. 12,046, July 30, 1889. 6d.

TEN to 20 lb. of rosewood sawdust, 20 lb. of wood pulp, 1 lb. of extract of logwood, $\frac{1}{2}$ lb. of potassium bichromate, $\frac{1}{2}$ lb. of sulphate of iron, 4 lb. of animal glue, $2\frac{1}{2}$ to 5 lb. of an albuminous substance such as bullock's blood, and any desired quantity of vegetable fibre (suitable to the purpose intended), such as flax, hemp or cotton, are mixed together to a uniform plastic mass and moulded into such articles as the various insulating parts of electric lighting, signalling, and telephone apparatus, picture frames, mouldings, &c., put away to dry and then subjected to a heavy finishing pressure at a temperature of about 300° F. The patentee uses rosewood sawdust because of a resinous oil it contains, which helps in forming a cohesive composition, while bullock's blood is used as a cheap source of albumen and also as a colouring material, logwood and sulphate of iron for the same purpose, and potassium bichromate to render the albumen and gelatin insoluble.

The composition is said to be black, insoluble, hard, a non-conductor of electricity, capable of being cut, worked, and turned, and of taking a high polish.

The proportions may be varied, and all the ingredients need not be used at once.—B. B.

A New or Improved Process for Waterproofing Materials or Fabrics and the like. J. Grunhut, South Shields, E. Gonty and F. B. Gonty, Leicester. Eng. Pat. 14,316, September 11, 1889. 4d.

THE fabric to be waterproofed is treated with a mixture of mineral oil, paraffin wax, and spermaceti; "benzole" may be substituted for the mineral oil, "whale fish bones or any other fish bones" for the spermaceti, and vaselin or stearin for the paraffin wax. A suitable mixture—although others may be used—consists of 4 pints of mineral oil, 1 lb. of paraffin wax, and 3 lb. of spermaceti.—B. B.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

Lime in Tanning Materials. M. Petrowitsch. Zeits. Anal. Chem. 28, 606—607.

A SAMPLE of valonia meal was found to contain 6.36 per cent. of ash containing 0.46 per cent. of lime, whilst an analysis of pure valonia gave 2.55 per cent. of ash with 0.24 per cent. of lime. The former caused large blue-black spots to appear on the tanned leather. It was also found to contain small pieces of the acorns of valonia, and little stones that appeared to be silicates. An analysis of gall-nut meal gave 3.10 per cent. of ash with 0.23 per cent. of lime.—C. A. K.

The Present Condition of the so-called Mineral-Tanning Industry. F. Knapp. Chem. Zeit. 13, 907, 996—997, 1027—1028 and 1058—1059.

A GOOD tanning material should fulfil the following conditions:—

1. It should prevent the skin from drying to a horny mass, by keeping its fibres separate.

2. It should possess a strong affinity for the raw skin, and should be absorbed in large quantity.

3. It should, when dried, be of a pliable and elastic nature, in order that it may not injuriously influence these qualities in the finished leather.

Chromic acid and its salts employed as tanning materials fulfil the first of the above conditions very perfectly, but the second and third very badly indeed. Chrome-tanned leather contains from 4—6 per cent. of chromium calculated as potassium bichromate. In the so-called iron tanning, a basic sulphate of iron is employed. It contains one molecule of Fe_2O_3 to two molecules of SO_3 . It forms with water a reddish-yellow solution, which dries down to a clear varnish. The fibre of the hides is not injured in the least by this compound. It is rapidly absorbed by raw skin, which retains it very well; heavy hides only require 4—6 days to be completely tanned. 100 parts of dry hide absorb 67 parts of iron salt from a solution of 25° B., and 177 parts from a solution of 33° B. The dry leather, therefore, contains 41 per cent. and 61 per cent. respectively of tanning salt. Leather made by this process is, however, not at all pliant, and is very liable to crack. Various plans have been suggested to obviate this difficulty. It was recommended to steep the hides in soap solution after removal from the iron bath. The iron soap formed is a very soft, pliant substance, and it was imagined that thus pliability would be restored to the leather. Practically the process is of little use. Iron and blood together have been used with success in St. Petersburg and in Brunswick. The hides are first steeped in the iron solution for 2—4 days, and then for a similar period in blood. The finished leather contains from 38—44 per cent. of the tanning material, and is at least equal in pliability and durability to ordinary leather. The saving in price of material, quite apart from any consideration of the time required for tanning, is from 40—60 per cent. Lately a new substance has been discovered to be used in conjunction with iron. Its nature has not been divulged, because it will probably be made the subject of a patent. Experiments with it have not as yet advanced beyond the laboratory stage. It possesses a great advantage over blood, in so far that it may be employed mixed with the iron salt. The mixed tanning material is rapidly absorbed by the skin, to which it imparts an agreeable brown colour. The finished leather contains about 43 per cent. of tanning materials, and is equal in pliability to leather prepared with tannin. This method is to be highly recommended because of its cheapness and speed of working. The leather obtained by it is full-bodied and takes grease well. From certain data the author calculates that by this method a saving of at least 90 per cent. in the prime cost of the tanning materials is made, compared with the ordinary tanning method.—H. T. P.

XV.—AGRICULTURE, MANURES, Etc.

Physiology of Tannin. Grundlinien zu einer Physiologie des Gerbstoffs, a Monograph. G. Krauss, Leipzig. 1889.

TWENTY-ONE experiments are given, comprising several hundreds of tannin determinations. In these are included the determinations of the amount of tannin in leaves under the various conditions of light, shade, and darkness, leading to the conclusion that light and CO_2 are essential agents in the formation of tannin in leaves. It was found that the outer leaves of a plant exposed to direct sunlight contain more tannin than the inner leaves. Only green leaves are capable of producing tannin. It is not correct to assume that tannin is a product of the assimilation of chlorophyll, for there are to be found leaves without number which assimilate tannin, though not producing it. For example, the leaves of oak, willow, and alder, though assimilating the elements of tannin in dull weather, do not develop that glucoside. The tannin produced in the leaves passes into the branches and roots, and no experimental evidence exists to show that tannin which has once passed into the rhizome undergoes further change; there is rather an increase of tannin in the rhizome through a production in the dark. As

to the use of tannin in nature, the author inclines to the opinion that its purpose is to protect the leaves producing it, either from being eaten, or from rotting, &c.

Leaves which have fallen contain as much tannin as during their best period of growth; this fact is taken to show that the leaf-tannin is of no value to the plant. The value must therefore be confined to the leaf.

During germination in the dark of seeds containing tannin (as those of oak and horse-chestnut), there is no falling off, but an increase in the amount of tannin.

XVI.—SUGAR, STARCH, GUM, Etc.

Improvements in Sugar Refining. E. O. Lippmann. Chem. Zeit. 13, 993—996.

IMPROVEMENTS in this branch of sugar manufacture are of comparatively recent date. The most important improvements are those of Steffen and Seyfert. These two improved methods are based on the principle of separating the molasses as completely as possible from the cane-sugar crystals. Seyfert's method consists in washing the moist sugar crystals in the centrifugal machine with paraffin oil of 220°—250° boiling point. By this means the molasses are almost completely removed from the cane-sugar crystals; but the purified sugar is not directly fit for consumption, because the oil imparts to it a disagreeable odour. This smell is completely removed by redissolving the sugar and boiling the solution. Solid sugar may be refined by feeding it into the centrifugal machine, either dry or mixed with paraffin oil, previously thickened by dissolving in it solid paraffin. It is then washed with oil as before. The following numbers are given: 100 parts of raw sugar, containing 95.8 per cent. of cane sugar, yielded by the old method, 65.24 per cent. of white sugar, 28 per cent. of after-products, and 6 per cent. of molasses. By the new method, 86.22 per cent., 4.85 per cent., and 8.25 per cent. respectively of these products were obtained; so that instead of 25 per cent. only 4 per cent. of the sugar needed further purification. The clear profit on 100 kilos. of raw sugar was 1.26 to 1.70 marks.

In Steffen's method a more or less pure sugar syrup is employed to effect the separation of the molasses from the sugar crystals. For this purpose the raw sugar or the molasses containing in suspension sugar crystals, is placed in a thin layer at the bottom of a tank, holding about 400—500 kilos., and washed with 16—32 portions of syrup of increasing purity, suction being applied by means of an air-pump. The process requires about 12—16 hours or more, much depending on the quality and evenness of grain of the raw material. An experiment with raw sugar yielded the following results:—1,000 kilos. of raw sugar, polarising 95 per cent. and containing 2.5 per cent. of water and 2.5 per cent. of non-sugars, were washed with 380 kilos. of pure syrup containing 66 per cent. of cane sugar. After making allowance for the sugar contained in the syrup, there were finally obtained 870 kilos. of pure sugar. Of this 71 per cent. = 618 kilos. existed in the dry state, and 28 per cent. = 244 kilos. in the shape of syrup of practically the same degree of purity as the syrup used for washing. In the working of this process it is of importance that the grain of the raw sugar should be as uniform as possible. The saving in cost of production of sugar by this method varies from 1 to 1.5 marks per 100 kilos. of raw sugar employed. The cost of the plant for a factory of average size is stated to be 300,000 marks.—H. T. P.

On Raffinose. Berthelot. Compt. Rend. 109, 548—550.

RAFFINOSE is commonly described as crystallising with five molecules of water. The author, however, obtained another hydrate when crystallising it from dilute alcohol, having a composition corresponding to the formula $\text{C}_{18}\text{H}_{32}\text{O}_{16} \cdot 6\text{H}_2\text{O}$. Under the influence of a good beer yeast raffinose ferments completely, but the author has observed that when a weak

ferment is used, such as some varieties of bakers' yeast, the fermentation stops at the end of 48 hours and proceeds no further even after several weeks. The amount of carbon dioxide, alcohol and remaining sugar are such as would be produced if raffinose were decomposed into a saccharose and a glucose which ferments, or two glucoses which remain unfermented. The unfermented sugar from 100 parts of raffinose possesses a reducing power corresponding to 35.7 parts of glucose.—A. L. S.

Estimation of Salts in Raw Sugar by means of its Electrical Conductivity. Zeits. f. Zuckerind. **39**, 638.

THIS process, which has been recommended by Reichert, has been carefully tested by Landolt, who finds that in its present form it is not sufficiently reliable, while the difficulties involved are so great that it will still require much work before the process can be put on a satisfactory basis.

—W. M.

Occurrence of Raffinose in Factory Products and the Cause of its Presence. Zeits. f. Zuckerind. **39**, 647.

LIPPMANN has made careful analyses of factory products from good normal beets, to confirm his former statement (this Journal, 1889, 632) that raffinose exists in the beets themselves, and agrees with Herzfeld's hypothesis that raffinose is due to a "vegetation process." Herzfeld regards it as still an open question whether raffinose is produced during processes in the factory, for instance, by diffusion at high temperatures, or exists as such in the beet, but he regards the latter supposition as more probable from physiological considerations of the plant life. He also says that the well-known pointed crystals are not characteristic of sugar containing raffinose, as the raffinose is frequently found in the syrup adhering to the crystals, and further that even when containing as much as 4—5 per cent. of raffinose the crystals exhibit no abnormal appearance.—W. M.

Manufacture of Invert Sugar. Zeits. f. Zuckerind. **39**, 738, 740, and 745.

AT the suggestion of Herzfeld, Tummeley and Vier have tried the inversion of cane sugar in aqueous solutions by means of sulphurous acid and carbonic acid under pressure. Tummeley found that sulphurous acid worked well. On a large scale it will be found best to use a solution containing 30 per cent. of sugar, invert it by boiling for half an hour with 1 per cent. of acid in wooden or earthenware vessels, remove the excess of sulphurous acid by boiling, and then dissolve cane sugar in the liquid until the desired degree of concentration has been attained. The small quantity of sulphuric acid derived from the sulphurous acid can be neutralised by the addition of sodium tartrate; the sulphurous acid expelled by boiling can be condensed and used again. Tummeley found that the inversion of a solution containing 16 per cent. of sugar together with 1 or $\frac{1}{2}$ per cent. of acid was complete in 15 minutes.

Vier tested the inversion of sugar with carbonic acid under pressure to check the accuracy of Lippmann's results. He was only able to effect a very slight amount of inversion after heating to 100° a solution containing 20 per cent. of sugar for four hours with carbonic acid under a pressure of nine atmospheres, and the same result was obtained by heating to 65° under a pressure of 13 atmospheres. He concluded that Lippmann had worked with very dilute solutions under special conditions, and had drawn erroneous conclusions as to the inversion of more concentrated solutions.

—E. E. B.

Oxidation of Maltose. E. Fischer and J. Meyer. Ber. **22**, 1941—1943.

WHEN maltose is dissolved in water and acted on by bromine in the cold for one or two days, it is oxidised to an acid which the authors have named *Maltobionic acid*. This may be obtained in a pure state from the above solution by precipitating with basic lead acetate, having first of all

removed the hydrobromic acid and excess of bromine. The precipitate is well washed and the lead removed by sulphuretted hydrogen. The clear solution is evaporated in a vacuum, extracted several times with hot alcohol and the extract precipitated with ether.

An almost colourless syrup is thus obtained, which has a strongly acid reaction. It is easily soluble in water, difficultly in alcohol and insoluble in ether. It does not reduce Fehling's solution, and is very similar to lactobionic acid (this Journal, 1889, 297). The salts are all easily soluble in water but do not crystallise readily; the calcium salt has a composition represented by $(C_{12}H_{22}O_{12})_2Ca$.

On heating maltobionic acid with five times its weight of 5 per cent. sulphuric acid, neutralising with barium carbonate and filtering, a solution is obtained which when evaporated to a syrup and extracted with alcohol leaves barium gluconate; the alcoholic extract contains dextrose which crystallises on concentration, the reaction taking place according to the equation—

The production of maltobionic acid shows that maltose contains an aldehyde group, and the general similarity of the products with those obtained from lactose shows that these two sugars are similarly constituted. The authors consider that maltobionic and lactobionic acids are comparable with arabic acid, which undergoes a somewhat similar decomposition when treated with dilute sulphuric acid.

—A. L. S.

The Reduction of Acids of the Sugar Group. E. Fischer. Ber. **22**, 2204—2205.

THE reduction of the carboxyl group contained in organic acids has hitherto not been effected. The author finds that this reduction is most easily performed in the case of acids of the sugar group. Gluconic acid, in cold aqueous solution, is rapidly converted by sodium amalgam into a reducing sugar, which is probably dextrose. Mannic acid (obtained by Hirschberger and the author by the action of bromine on mannose) yields mannose. Arabic, mannic, and rhamnosic acids, as well as the polybasic acids of the sugar series, are also reduced by sodium amalgam. On the other hand, glyceric, tartaric, and malic acids are not affected. It would seem that the reducibility of an acid is in some way connected with its power of forming a lactone.

—H. T. P.

On Pentacetyl Galactose and Dextrose. E. Erwig and W. Koenigs. Ber. **22**, 2207—2213.

PENTACETYL galactose is obtained similarly to the corresponding dextrose compound (this Journal, 1889, 718) by heating galactose with acetic anhydride and sodium acetate; the product of the reaction is evaporated repeatedly with alcohol until the excess of acetic anhydride and acid is expelled, and then extracted with alcohol. Pentacetyl galactose crystallises from the alcoholic extract in well-defined rhombic crystals. It is different from the gummy pentacetyl galactose described by Fudakowsky (Ber. **11**, 1071), and is therefore distinguished by the name of *crystalline* pentacetyl galactose. Its melting point is 142°. It is more insoluble than the corresponding dextrose compound in cold alcohol; it is fairly easily soluble in hot alcohol, ether and boiling water.

This compound and the corresponding one of dextrose react very similarly with reagents. They easily reduce Fehling's solution on warming; are completely saponified on boiling with dilute sulphuric acid with regeneration of the original carbohydrides; not easily decomposed on boiling with water; do not form phenylhydrazine or similar compounds, and are not attacked by phosphorus pentachloride or oxidised by bromine water. Potassium permanganate or bichromate slowly oxidises them to carbon dioxide and water, but without producing appreciable amounts of fatty acids.

The authors consider that all these reactions tend to indicate that these acetyl derivatives do not contain an aldehyde group, and they discuss their constitutional formulae.

As octaacetyldiglucose is decomposed when warmed with acetic anhydride and zinc chloride with production of pentaacetyldextrose; experiments were made to determine whether octaacetylmaltose undergoes a similar decomposition, but this compound was found to be unacted upon under these conditions. Cane sugar and inulin are quickly inverted when heated with 0.5–1 per cent. zinc chloride solution, and although starch when heated for eight hours with a 5 per cent. solution does not yield bodies which reduce Fehling's solution, yet it is probable that the above decomposition of octaacetyldiglucose is accompanied by simultaneous inversion.—A. L. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

On the Possibility of communicating the Bouquet of a High Class Wine to an Ordinary Wine by Changing the Ferment. A. Rommier. Compt. Rend. 108, 1322–1324.

STARTING from Pasteur's observation that beer fermented with wine yeast smells of wine, the author has succeeded on the small scale in communicating the bouquet of the wines of Champagne, Côte d'Or, and Burgundy to the *vin ordinaire* of the South of France, a poor wine almost without bouquet and containing about 8 per cent. of alcohol. Three lots of the grapes, separated from the stalks, were watered with a small quantity of yeast cultivated from the respective sources above mentioned, then crushed, and the must from each introduced into a large flask with two tubulures, one furnished with a delivery tube dipping under water to conduct away the carbon dioxide, and the other with a tap for withdrawing the fermented juice. A fourth flask contained the juice of the same grapes grown under glass, and therefore containing (according to Pasteur) none of the natural yeast spores; this lot was sown with champagne yeast. The first three fermented in 10 days, the last in 13, at a temperature of 22–28° C. On the third day of fermentation, enough sugar was added to each to raise the percentage of alcohol from 8 to 13 per cent. After fermentation the four samples were drawn off and cleared in well-filled flasks and then bottled; each had a pronounced bouquet of the wine from which the respective cultivation of yeast was obtained.—J. M. H. M.

On the Alcoholic Fermentation of Honey and the Preparation of Mead (Hydromel). G. Gastine. Compt. Rend. 109, 479–482.

SOLUTIONS of honey in many cases undergo alcoholic fermentation very slowly even under the most favourable conditions of dilution, &c. The author finds that the cause of this is that honey does not contain sufficient quantities of nitrogenous and mineral substances for the free growth of yeast; for when ammonium salts and the sulphates and phosphates of potassium, magnesium and calcium are added in suitable proportion to honey which has been sown with yeast, it ferments very readily. The author considers that when the preparation of mead has been successfully accomplished, it has been due to the accidental introduction of the above nitrogenous and mineral substances.—A. L. S.

On the Occurrence of Sulphurous Acid in Beer. F. Pfeifer. Zeits. f. d. gesammte Brauw. 1889, 12, 345.

THE presence of sulphurous acid in beer has generally been attributed to the use of "sulphured" hops; the author, however, finds that only a very small proportion, if any, of the sulphurous acid is due to the hops, but that it is a product of fermentation, and in a fermenting liquid the amount of sulphurous acid increases as the fermentation continues.

—E. E. B.

PATENTS.

Means by which Alcoholic Liquors may be Rendered more Wholesome. E. A. B. Beaumont, Brighton. Eng. Pat. 11,965, October 18, 1888. 4d.

THIS is a proposal to convert beer, porter, wine, spirit, liqueur, &c., into medicines by adding suitable quantities of *Cascara sagrada* or *Rhamnus frangula*.—A. L. S.

Improvements in Treating or Seasoning New and Purifying Old or Foul Casks, Vats, Backs, or other Vessels. H. Hill, Camberwell. Eng. Pat. 15,440, October 26, 1888. 4d.

A SOLUTION containing an alkaline gallate or tannate is used for this purpose. It is prepared either from gallic or tannic acid or some vegetable substance containing them, such as oak and other barks, galls, hops, &c.

A stock solution is prepared of one part of the acid to six of water, or an extract of one of the above vegetable substances of a specific gravity 1.150, combined with one-tenth of its weight of sodium or potassium carbonate.

For use this is diluted with 200–250 parts of water for beer, rather less for wine or spirit casks, and applied hot. The cask is kept hot by means of steam blown in occasionally for two to four days. In the case of foul casks this treatment has to be repeated one or more times.

After emptying and rinsing, the process is completed either by treatment with a solution of chloride of lime (1 oz. to 36 gallons) followed by a solution of calcium bisulphite (sp. gr. 1.030); or with a solution of potassium or sodium permanganate (1 to 250 of water); or with a solution of zinc chloride (1 to 150 of water).—A. L. S.

Improvements in the Purification of Alcohols. C. Philippart, Paris, France. Eng. Pat. 15,794, November 1, 1888. 6d.

IN this invention the well-known property of bisulphites, of combining with aldehydes and ketones to produce compounds insoluble in alcohol, is made use of in order to effect the removal of these substances from alcohol residues and rectified spirit. Any of the common bisulphites may be made use of, or the base may be added first and then a sufficient quantity of sulphurous acid to form the bisulphite. The two products may be separated either by decantation, filtration or distillation. The compounds with the bisulphite may be readily decomposed, either by converting the bisulphite into a normal sulphite by adding sufficient of a powerful base, or by oxidising the sulphite to sulphate, or by replacing the sulphurous acid by a more powerful acid.

—A. L. S.

A New or Improved Non-Alcoholic Beverage. M. H. Beaufoy and J. Cartwright, London. Eng. Pat. 17,914, December 7, 1888. 4d.

THIS beverage may be manufactured as follows:—A sweet wort prepared in the ordinary way from malt is boiled for a short time with an extract of hops, obtained by boiling hops with water. When this is cold, a little burnt sugar is added to colour it and a sufficient quantity of a strong solution of sulphurous acid to prevent fermentation. The mixture is fined with isinglass, and when bright bottled off and aerated as in the manufacture of mineral waters.

—A. L. S.

Improvements relating to the Separation of Mixtures of Ethyl Alcohol and Water from Fusel Oil and other Impurities, and to Apparatus therefor. I. Traube, Hanover, Germany. Eng. Pat. 17,972, December 8, 1888. 8d.

THIS process depends on the fact that mixtures of ethyl alcohol and water may be separated from their impurities by the formation of strata in the liquid, which may be caused by the introduction of certain salts (this Journal, 1889, 812). Among those which may be used are potassium and sodium carbonates, potassium and sodium hydroxides, sodium phosphate, the sulphates ammonium, sodium,

magnesium and zinc, and potassium and ammonium alums. The patentee finds that the success of the process depends on the concentration and temperature of the solutions, on the number of strata which are produced and the special mode in which the same is carried into effect.

The apparatus consists of a series of settling vessels, the upper portion of each being narrower than the body of the vessel; they are fitted with heating coils and suitable connecting pipes which are shown in detail in the drawing accompanying the specification. The vessels are partly filled with an aqueous solution of sp. gr. 1.2 of one of the above mentioned salts (potassium carbonate is found most suitable), which is heated to 40°–78° C. Raw spirit containing 80 per cent. of alcohol is added to the first vessel until an upper stratum of liquid is formed of $\frac{2}{20}$ to $\frac{1}{10}$ of the total volume. If spirit of another strength be used, the strength of the salt solution must be so arranged that the same proportion of water, alcohol, and salt exists in the resulting mixture. The upper stratum being very impure is run off into a special reservoir; a second stratum is then produced in the same manner as the first by adding a further quantity of spirit, the second stratum is used to produce a first stratum in the second vessel, and which when formed is run off into the reservoir containing the first stratum from the first vessel. A third stratum is produced in the first vessel in the same manner as before, this is used to produce a second stratum in the second vessel which is then used to produce a first stratum in the third vessel. These operations are continued until the lower stratum in the first vessel has become sufficiently pure, when it is run into the still; the first vessel is then filled with fresh salt solution and becomes the last of the series.

—A. L. S.

Improvements in the Treatment of Ground Malt for Brewing Purposes, and in Apparatus therefor. H. A. Birrell, Cardiff. Eng. Pat. 18,286, December 14, 1888. 8d.

This invention has for its object the restoration of certain properties, imparted to malt during kiln-drying, which have been lost owing to long storage. This is effected by passing the products of combustion of anthracite coal, cooled to a temperature of 150° F. or thereabouts, through the ground malt when in the hopper over the mash tun. For this purpose the hopper, as commonly used, is fitted with an inner casing of some perforated material, leaving a space between them. Into this space the products of combustion from a furnace burning anthracite coal are forced by a fan, and, passing through the perforated casing, diffuse through the ground malt. It is claimed that this is superior to the method for "retorrefying grist" by hot air at 150° F., as in this case the air is not sterilised by heating to the temperature, whereas in the former case the passage of the air through the fire effectually sterilises it. Drawings of the apparatus are given in the specification.—A. L. S.

Improvements in the Treatment of Alcohols and Alcoholic Liquors for the Purpose of improving their Quality. C. Philippart, Paris, France. Eng. Pat. 18,422, December 17, 1888. 6d.

THE inventor claims that the quality of alcohol, wine, liqueurs, &c. is improved by treatment with oxygen. He gives four alternative methods: (1) passing a continuous current of oxygen or air through the liquid under treatment; (2) passing a continuous stream of ozonised oxygen or air through the same; (3) the addition of oxygenated water or some easily decomposed peroxide ("lead, manganese, &c."); (4) the addition of some stable peroxide which may be decomposed by some suitable reagent producing an insoluble salt, e.g., barium peroxide and carbonic acid.

—A. L. S.

Apparatus for mixing Water with Malt for Supply to Mash Tuns. D. R. J. J. G. Morel, Pas-de-Calais, France. Eng. Pat. 13,451, August 26, 1889. 6d.

THE apparatus is to be fixed over the mash tun and consists of two concentric tubes, the walls of the inner one being pierced with holes. The annular space between the tubes

is in communication with the supply of mashing water, and the inner tube is placed under the mouth of the malt hopper. When the malt is falling through the inner tube, the water is turned on into the outer one, and, issuing in jets through the perforations above mentioned, mixes with the malt.—A. L. S.

Improvements in or relating to the Manufacture of Beer, Ale, Porter, and the like. L. Frisch, Chicago, U.S.A. Eng. Pat. 14,642, September 17, 1889. 8d.

THIS is an improved mashing process when raw grain is employed. By following out the details here given, the inventor states that a better yield may be obtained than by any other known method.

The cereal is mashed with water at about 30° R. in a closed boiler, and steam led in until the temperature rises to about 119° R., the whole being kept well stirred by suitable gear; after standing a short time, the steam is allowed to blow off, and the pressure in the boiler further diminished by a vacuum-pump until the temperature falls to about 59° R. A quantity of malt, containing sufficient diastase to convert the whole of the starch in the cereal, is mashed at about 38° R. and run into the liquid in the boiler, the whole being stirred until most of the starch contained in the liquid has disappeared; the temperature is then raised to about 70° R. by injecting steam, when the whole is led into a large mash tub containing a mash of two-thirds of the remaining quantity of malt to be used for the brew. After complete mixture the remaining one-third of the malt is added, and the mashing finished as usual. Drawings illustrating the method are given in the specification.

—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

The Decomposition of Food, and its Prevention. W. Hempel. Dingl. Polyt. J. 274, 82–95.

FROM a series of experiments, the author concludes that the three essentials for the perfect preservation of meat are cold, dryness and oxygen. Meat suspended over concentrated sulphuric acid, the drying being further hastened by good ventilation, kept perfectly for five months. Ozone also has a remarkable preservative effect on meat. Meat placed in a well ventilated vessel in which the silent discharge took place continually for 14 days, not only kept during that time, but was perfectly good nine months afterwards, having been exposed simply to the fresh air during the interval. In order to secure the above-named conditions, the author recommends meat safes to be made according to the principle laid down in the sketch, Fig. 1. In this the ice, used as a cooling

Fig. 1.

agent, is kept in a separate compartment, and does not, therefore, make the air damp at all. The safe is ventilated by means of the openings *a, a, b, b*. In the openings *b, b*, are placed frames containing shallow dishes of concentrated sulphuric acid *c, c*, Fig. 2. The air becomes dry and cold as

Fig. 2.

soon as it enters the safe from above, and being consequently denser, circulates downwards and passes out at *a, a*.

Where much larger safes are required, the air is dried by simply cooling it. Such an arrangement is shown in Fig. 3,

Fig. 3.

in the upper part of which a coil of piping is situated. The fresh air enters at *a*, and being cooled deposits its moisture in the tray *C*, and passes by *b* and *c* into the safe. This is not cooled specially, the cooled dry air maintaining a sufficiently low temperature. After the air passes by *c* into the lower part of the safe, it comes into contact with the moist meat, and, as it takes up moisture, its density is again lowered and the direction of the current changed into an upward one, the air passing out at *d*. Fig. 4 shows the section of another safe on the same principle.

Fig. 4.

A is the space for the meat; *B* the ice compartment; *C* the tray for collecting the water from the melting ice; *D, D*, the ventilators; *K* the tap for drawing off the water. The author finds that of gases, besides ozone, the vapours of nitric acid, nitrous acid, chlorine and chlorous acid, have a wonderfully preservative effect on meat when allowed, in small quantity, to pass with the dry cold air over it. Such meat, after exposure for some days to air containing these vapours, was hung up exposed to the ordinary atmosphere for months, after which it was perfectly sound, though dried up very much.—J. W. L.

PATENTS.

Improvements in the Preparation and Treatment of Extract of Tea. G. Christopher and R. W. Leftwich, London. Eng. Pat. 14,877, October 16, 1888. 6d.

EXTRACT of tea may be prepared by evaporating an infusion of tea to dryness in a vacuum pan. Finely ground, this is mixed with such proportion of dry powdered gelatin that when dissolved in boiling water little or no deposit occurs, nor is the liquid glutinous in character. Such a preparation obviates the injurious effect of tannin on the digestive organs. Lozenges of the mixture of gelatin and extract of tea mixed with powdered sugar may be prepared by well-known methods. If the tea from which the extract is made contain a large quantity of tannin, this may be removed by the addition, at a temperature of 150° F., of a smaller quantity of gelatin than is requisite to keep the resulting tannate of gelatin wholly in solution. Evaporation to dryness is then effected, water added and the whole digested at 135° F.; the plastic tannate of gelatin is removed by filtration, or otherwise, and washed. The extract and washings are finally evaporated to dryness, for use as first described.—C. C. H.

An Improved Preparation to be used as a Substitute for or in Combination with Coffee. E. Edwards, London. From I. Lapeyrère, Mlle de la Réunion, France. Eng. Pat. 14,945, October 17, 1888. 6d.

For the inert or somewhat injurious substances, *e.g.*, chicory, usually mixed with coffee, the patentee substitutes a substance, similar to coffee in composition, known as *Mussaenda-Borbonica*. This may be roasted with the raw coffee berries, and mixed in any proportion with, or entirely substitute, the coffee. The infusion is prepared in the manner coffee is usually prepared.—C. C. H.

Improvements in and relating to the Manufacture of Milk-Powder and Effervescent Beverages. W. Gerbel, Rorschach, Switzerland. Eng. Pat. 1301, January 22, 1889. 6d.

The milk is heated to 100° or 105° F., rennet or tartaric acid added, and the curd so formed separated from the whey in any convenient manner. The curd is finely chopped or minced, and, upon a hearth or in an oven, dried at a temperature of 110° to 120° F. for a period of six hours, during which time it is frequently turned or stirred. After cooling for a similar period it is again heated and cooled, this process being repeated three or four times. It is then ground finely for use. The whey, after separation from the casein, is freed from whey cheese by heat and the addition of tartaric acid, the cheese being added to the casein before its treatment as above described. It is then filtered, mixed with enough grape, cane or milk sugar to generate sufficient carbonic acid gas to give an agreeable flavour, or it may be saturated with carbonic acid gas, as in the production of aerated beverages, and bottled.

—C. C. H.

Improvements in Bread Fermentation. A. B. Lennox, T. Field, and W. Brown, London. Eng. Pat. 11,225, May 3, 1889. 4d.

In place of part of the potatoes ordinarily employed to promote a vigorous fermentation in the yeast used in the making

of bread-stuffs, the patentees use a special form of malt sugar, which they call "Fermentol." In this way they claim the production of a lighter and better bread, with a saving of 25 per cent. of yeast and 50 per cent. of the potatoes usually employed.—C. C. H.

(B)—SANITARY CHEMISTRY.

On Purification of Effluent Water as carried out at the Establishment of W. Spindler at Spindlersfeld. C. F. Göhring. Chem. Zeit. **13**, 851.

ABOUT 10,000 cubic metres (over 2,200,000 gallons) of effluent water from dye and bleach works, sewage, &c., are treated daily in the above establishment. It is first treated by decomposition of the soapy water for recovery of the fat. The water is purified so far by settling in enormous reservoirs, the reactions occurring in the heterogeneous mixture. The coarser filth is thus separated and contains a mixture of iron oxide, tannin, colouring matter, fatty acid, salts, &c. The water, however, is still far from pure, and develops fungi. The average daily analysis of such is: temperature, 20°; colour, blue-black; reaction, acid; smell, like dyewood extract; suspended matter, tannate of iron, extractive, textile fibre, &c. On filtration, brownish-black and containing in 100,000 parts—

Total solids.....	88.0
Fixed residue.....	53.0
Volatile residue.....	35.0
Lime.....	6.52
Magnesia.....	0.81
Ferric oxide and alumina.....	4.42
Sulphuric acid.....	12.67
Chlorine.....	5.11
Nitric acid.....	1.72
Nitrous acid.....	None
Ammonia.....	0.23

The water roughly filtered through gratings is pumped into a lesser mixing basin and treated with milk of lime and magnesium chloride solution, pumped thence to larger settling basins, from which after a time the water is run off. The purification thus effected and that due to the oxygen absorbed during an aëration effected by mechanical means produce a satisfactory result.

Analysis shows temperature 12°; colour, clear reddish; reaction, neutral; smell, none; suspended matter, none.

In 100,000 parts—

Total solids.....	66.01
Fixed residue.....	54.00
Volatile residue.....	12.01
Lime.....	15.72
Magnesia.....	1.04
Ferric oxide and alumina.....	0.17
Sulphuric acid.....	11.84
Chlorine.....	6.55
Nitric and nitrous acids.....	None
Ammonia.....	None
Total hardness.....	17.01
Permanent hardness.....	16.08
Temporary hardness.....	0.21
Oxygen absorbed.....	9.72

Thus the greater part of the ferric oxide and all of the deleterious organic matter has been removed; the water, moreover, no longer develops fungi.

The fatty sludge has a specific gravity of 0.850, and contains moisture 10 per cent., fatty acids 53 per cent., mineral acids, tannin, colouring matter, fibre, &c. This is eventually pressed in a steam press for recovery of the fat.

The sludge from the settlers is dark green with moisture 81 per cent.; combustible and volatile residue, 11.8; ash, 7.2; the latter containing lime, 22.4; magnesium, 10.3; peroxide of iron and alumina, 15 per cent.—D. A. S.

Investigations into the Efficiency of the Sand-Filters in use at the Zurich Public Waterworks. A. Bertschinger. Vierteljahrsschr. d. naturforsch. Ges. in Zürich, **34**, Pt. 2.

SINCE 1886 Zurich has been supplied daily with 20,000 cubic metres of water derived from the lake at a distance of 200 metres from the shore, and conveyed through iron pipes to the filters. These are five in number, two of which are arched over, and the others uncovered; each has a filtering surface of 672 sq. metres. The filtering material rests on a brick grating and consists of the following layers commencing from the bottom: 5—15 cm. of coarse gravel, 10 cm. of garden gravel, 15 cm. of coarse sand and 80 cm. of fine sand. The rate of filtration is regulated separately in each filter.

As soon as the diminution in pressure of the water, due to the resistance of the filter, is 60 to 80 cm., the filter is cleaned by allowing the water to run off and removing the top layer of sand to a depth of 2 cm. as this is found to contain the whole of the mud. The filter is then filled up with filtered water from below and washed by allowing this to overflow. After filtration has recommenced the first portion of the filtrate is rejected. The covered filters require to be cleaned once in 77 days, and the uncovered once in 48 days. As soon as the layer of fine sand has been reduced to a thickness of 50 cm. fresh sand is substituted or more added until the depth is again 80 cm.

Chemical and bacteriological examinations of the water before and after filtration show that:—

1. The sand filtration materially improves the chemical purity of the water.

2. Under normal conditions the filtered water is free from germs, although a few are taken up again in the later stages of the filtration and also after it.

3. The rate of filtration (at least between 3 and 12 cubic metres of water per sq. metre of filtering surface in 24 hours) has no influence on the purity of filtered water, all spores being removed by the uppermost layer of sand.

4. After cleaning the filter, the water which first passes through it is not in a normal condition, but contains many germs, an efficient layer of scum not having had time to collect on the sand though the chemical purity of the filtered water is unaffected.

5. When the filters have not been used for some time the water which first passes through them contains many more bacteria than usual owing to their rapid multiplication in the stagnant water, but the chemical purity of the water is again not materially different from the normal filtered water.

6. No difference exists between the water from the covered and from the uncovered filters, either as regards chemical purity or freedom from bacteria.

Numbers 3 and 6 of the above results are new and of great importance, for the former shows that water can be filtered much more rapidly than has hitherto been supposed (at Berlin the maximum rate of filtration allowed has been 3 metres daily). Further, the belief that open filters remove micro-organisms from water much more completely than covered filters is thus shown to be erroneous.—E. E. B.

The Examination of Potable Waters. H. Fleck. Zeits. f. angew. Chem. 1889, 580.

ACCORDING to the author the following points are essential in a good potable water:—

1. It must be clear, colourless, and odourless. Any sediment from the water may only contain very few micro-organisms. 2. It must give a colourless residue on evaporation. Even if colouration be due to the presence of iron and manganese compounds the water must be looked upon as impure. 3. On being kept for eight days in a closed vessel it must not show brown or green organisms. 4. It should not require more than 2 mgrms. of oxygen per litre, for oxidation. 5. It should not contain more than 0.1 mgrm. of ammonia per litre, and should not become cloudy on being boiled with alkaline silver solution. 6. It should not contain more than 20 mgrms. of chlorine and 10 mgrms. of nitric acid if the amount of ammonia present exceed the above-mentioned limit. 7. It must not contain a trace of nitrons

acid. 8. It may not contain phosphoric acid. 9. It should not show more than 30° (German) of hardness.

In examining the water for sewage contamination, 1 to 2 litres of the water should be evaporated to dryness with a little tartaric acid, the residue extracted with absolute alcohol, the solution evaporated to dryness and the residue moistened with potash lye. If contaminated with organic matter a distinct odour of faeces will be detected.

—F. W. T. K.

Water Filtration. C. Piefke. Zeits. f. angew. Chem. 1889, 580—586.

The conclusions arrived at are briefly as follows:—The purification of water when filtered through sand must not be looked upon as due to absorption or oxidation of the organic matter in it, but to the fact that the sand acts as a mechanical filter and holds back suspended matter and bacteria, which latter exert a fermentative action on the organic impurities in the water. This will explain why fresh sterilised sand exerts no filtering action on the water, whereas a sand filter which has been in use for some time and has got somewhat dirty, especially in the upper layers, purifies the water, providing the rate of filtration be not too rapid for the particular class of sand and the quality of the water undergoing filtration. The upper sand layers retain inorganic sediment, if not too fine, and bacteria; these latter feed on the organic materials in the water, and the products of fermentation and unfermentable matter alone pass through. The deeper layers of sand hinder the passage of sediment and of bacteria, which latter are perhaps somewhat more easily held back owing to their slightly viscous nature, and provided the flow of water through the sand is not too rapid, they are not easily washed away again. Of course, after a certain period, deeper and deeper layers of the filter get more and more contaminated. It is important, therefore, to see that the lower layers of a sand filter, the filtering action of which is more of a mechanical nature, consist of clean sand to start with which should not be allowed to get too contaminated.

There seems very good reason to believe that such organic matter as is left after filtration is innocuous, in so far as it represents fermented material and is, therefore, not liable to further fermentation or putrefaction. The point of greatest importance which has to be noticed is that the rate of filtration should be sufficiently slow for the quality of water to be filtered. The richer in micro-organisms the water is, the slower the filtration should be. If the rate of filtration be carefully attended to, the question of the thickness of sand becomes a point of minor importance, for, with a moderate rate of flow, a layer 0·7 m. thick was found to act all but as efficiently as one 1·4 m. thick, which latter was practically as effective as one 2·1 m. thick, the water moving at the same rate. A rate of flow of 0·1 m. an hour should not be exceeded unless absolutely necessary. With impure waters the rate of flow should be much less.

The "rate of filtration" is measured by the height of the column of water which sinks through the bed of sand in an hour. To determine from this "rate of filtration" what the rate of flow is in the sand itself it is necessary to know the volume percentage of the pores in the sand, *e.g.*, with a "rate of filtration" of 100 mm. an hour and a sand, the volume percentage of which is 25 per cent., the "rate of flow" in the sand itself will be $4 \times 100 = 400$ mm. an hour.

—F. W. T. K.

People Poisoned in 1888.

THE Registrar-General reports that, of the 701 people who were poisoned in 1888, 377 were males and 324 females. Of the males, 260 were in the accidental and 117 in the suicidal class. The former included 172 females, and the latter 151 females. It may be said that one out of nearly every five men, and one out of nearly every four women who commit suicide resort to poison.

The following are the particulars of the poisons which were used with fatal effect, and the frequency with which they were used:—

	Accidental.	Suicides.
Arsenic.....	5	5
Mercury.....	4	1
Lead.....	106	1
Sulphate of copper.....	1	..
Antimony.....	1	..
Bichromate of potash.....	2	..
Iodine.....	1	..
Chloride of zinc.....	2	..
Ammonia.....	5	4
Phosphorus.....	9	11
Sulphuric acid.....	5	6
Nitric acid.....	2	4
Hydrochloric acid.....	6	14
Oxalic acid.....	3	19
Carbolic acid.....	37	64
Acetic acid.....	1	..
Benzoline.....	1	..
Camphorated oil.....	1	..
Opium, laudanum, morphia.....	35	61
Bateman's pectoral drops.....	1	..
Cough elixir.....	1	..
Chlorodyne.....	10	1
Alcohol.....	6	..
Parazoline.....	1	..
Narcotic.....	3	3
Chloral.....	1	2
Colchicum.....	1	..
Belladonna.....	6	2
Prussic acid and oil of almonds.....	2	20
Hemlock.....	2	..
Colocynth.....	1	..
Aconite.....	4	..
Thorn apple.....	1	..
Yew leaves.....	1	..
Fungi.....	2	..
Strychnia, nux vomica.....	4	17

Salts of lemons.....	..	1

	Acci- dental.	Suicides.
Corrosive acid	4
Paraffin	1
Turpentine	1
Cyanide of potassium	10
Vermine killer.....	..	21
Dynamite.....	..	1
Kinds not stated.....	20	44

By lead-poisoning is meant the disorder which workers in lead factories suffer from. The number was slightly higher than in the year preceding. The principal feature of the above returns is the remarkable increase in the number of deaths from carbolic acid. This is by no means a new fact, for the rate at which people were dying from this poison in the summer of 1888 caused at the time considerable public alarm and an agitation to have the sale of the acid restricted. The figures before us show that the actual number of deaths was 101, as compared with 52 in the year before. With this exception the figures on the list are much similar to the average. Oxalic acid is lower in the suicide class, vermine-killer higher by six, and strychnine by five. Opiates are 10 higher in the same class, and mineral acids on the whole lower. Chlorodyne caused a few more accidental deaths.

PATENT.

Improvements in the Treatment of Towns' Refuse and other Putrescible Matters. A. Bobrownicki, London. Eng. Pat. 13,761, September 24, 1888. 6d.

EXCRETA or domestic refuse as collected by the "Pail System," wet sewage, sludge and the like, are treated by this process in order to render them innocuous and also to partially dry them. The substances named are subjected, in a variety of ways described in the specification, to the action of the products of combustion of fuel or of the distillation of coal, tar, resin and other fuels and hydrocarbons. When the putrescible matter is possibly infected with the germs of cholera, small-pox, or other such diseases, the temperature of the gaseous bodies effecting the treatment may with advantage be as high as 200° C. to 300° C. The injection of the vapours may be effected by means of a fan or blower.—C. C. H.

(C)—DISINFECTANTS.

PATENTS.

Improvements in Disinfectants and Compounds for the Supply of Sulphur Dioxide for other Purposes. J. E. Reynolds, Dublin. Eng. Pat. 15,676, October 31, 1888. 4d.

THE patentee styles the disinfectants prepared as hereafter described "Thiocamf Disinfectants." Camphor is treated with cooled sulphurous anhydride in a suitable vessel, e.g., a Woulfe's bottle, and the liquid resulting saturated with from 30 to 35 per cent. of its weight of sulphurous anhydride. With this may be mixed various disinfectants, e.g., benzoic and salicylic acids, boracic anhydride or mercuric chloride, oil of eucalyptus, nitrobenzene, phenols, &c. Such a mixture when exposed on a large surface, preferably over a vessel containing hot water, gives off large volumes of powerful disinfectant vapours; the residue is useful for cleansing woodwork.—C. C. H.

Improvements in Apparatus for Distributing Disinfectants. T. Rowan, Weston-super-Mare, and L. Hakeman, London. Eng. Pat. 15,925, November 3, 1888. 8d.

THE accompanying figure shows the construction of the improved apparatus. The stop-cock A is attached to a

Fig. 1.

water-main, and from the end of pipe at C the water issues in jets which impinge on each other and so form a fine spray or mist. The vessel G contains the disinfectant in a liquid form, which is displaced therefrom by a regulated fall of water from tap B; the drops of disinfectant displaced meet

Fig. 2.

the jets issuing at C in the basket b and thus become intimately mixed therewith and well diffused. This form of apparatus is adapted for the disinfection of sewers, and for this purpose is fixed at a convenient distance above the sewer in the manholes usually provided as shown in Fig. 2.

—C. C. H.

Improvements in the Preparation of Antiseptics, Disinfectants, and Sanitary and Bleaching Reagents. C. T. Kingzett, London. Eng. Pat. 15,994, November 3, 1888. 4d.

THE bisulphates of potassium and sodium act as powerful antiseptics and preservatives. If employed in the solid form as powder, crystals or tablets, they are impregnated with five or ten per cent. by weight of "Sanitas oil" or other

similar antiseptic. If used as a solution, five to ten per cent, by weight is dissolved in solutions of hydrogen peroxide capable of yielding five to ten times their volume of oxygen on decomposition. The proportions above given may be varied.—C. C. H.

An Improved Compound or Composition for Developing Ozonised Oxygen. J. E. P. Meyer, Golden, Colorado, U.S.A. Eng. Pat. 16,463, November 13, 1888. 6d.

The patentee's object is a simple mode of preparing ozone in sick-rooms. Dry powdered barium permanganate and sodium bisulphate are intimately mixed in the proportion of 25 per cent. by weight of the former to 16 per cent. of the latter, and an inert body such as barium sulphate may be added to give bulk. If sufficient water be added to a portion of such mixture so as to form a thick syrup, ozonised oxygen will be evolved.—C. C. H.

Preserving Shell Fish for Bait, and Utilising the Shells thereof. J. Hunter, Greenock. Eng. Pat. 16,660, November 16, 1888. 4d.

The fish are removed from the shells, and steeped in an aqueous solution of boracic acid and glycerin. The shells are ground, dissolved in acid, and used as a manure.—C. C. H.

An Improved Antiseptic Compound for Preserving Perishable Articles. W. H. Daniels, Chicago, U.S.A. Eng. Pat. 2858, February 18, 1889. 4d.

This specification describes improvements upon Eng. Pat. 17,843 of 1888. The compound there described consisted of a mixture of sugar, saffraas, sulphur, cinnamon, and potassium nitrate in proportions specified. The improved compound contains sugar and saffraas in about one-fourth the proportion formerly given: Sulphur, 16 oz.; sugar, 1 oz.; saffraas, 1 oz.; cinnamon, 2 oz.; and potassium nitrate, 2 oz. are mixed and ground together so as to form a homogeneous mass. The perishable articles are submitted to the fumes of a portion of the compound ignited in a closed chamber. —C. C. H.

Improvements in Sanitary and Antiseptic Preparations or Compounds. R. Hannan, Glasgow. Eng. Pat. 5984, April 8, 1889. 4d.

Common borax and boracic acid are mixed together in a finely divided state, preferably in the proportion so that when heated at 212° F., and evaporated to dryness, a "quadriborate of soda" will be formed. One part of this is intimately mixed in a grinding mill with 40 parts of a soluble salicylate, preferably sodium salicylate, and an aromatic substance, e.g., camphor, or oil of lavender added. The compound so produced is highly antiseptic in character, and may be used for the preservation of animal food substances and for surgical dressings. Whilst possessing high antiseptic properties it is non-poisonous.—C. C. H.

An Improved Manufacture of Absorbent Fabric. M. Chotzen and O. Silbermann, Breslau, Germany. Eng. Pat. 12,367, August 3, 1889. 4d.

COMPRESSED wadding, impregnated with any antiseptic substance, is enclosed between two sheets of gauze affixed thereto by roller pressure. Flannel, muslin, or thin sheets of paper may be used instead of wadding and gauze. The fabric so prepared is adapted for surgical purposes.—C. C. H.

XIX.—PAPER, PASTEBOARD, Etc.

On Colloid Cellulose, Soluble and Insoluble, and the Composition of Parchment Paper. C. E. Guignet. Compt. Rend. 108, 1258—1259.

FILTER paper washed with hydrochloric and hydrofluoric acids is nearly pure cellulose. Superior cotton may also be used for experiments, but yields more greasy products. Treated with sulphuric acid of 50° B. cellulose yields a transparent gelatinous mass, which does not change, even in the presence of an excess of acid, though is quickly changed into dextrin when heated to 100° C. Pure colloid cellulose is soluble in water, forming a slightly milky liquid, which filters easily and does not become clear, even after standing for days. The solution is dextro-rotatory, and is precipitated by small quantities of foreign matter. Colloid cellulose does not reduce tartrate of copper or sodium, it differs in that respect from the achroo-dextrins. Dried on marble, coated with vaselin, it forms a semi-transparent brilliant film, and plunged into sulphuric acid of 55° or 60° B., it is rendered insoluble, a partial formation of dextrin taking place. Nitric acid produces the same effect upon it as on ordinary cellulose. The properties of colloid cellulose explain some peculiarities in the manufacture of parchment paper. Certain parchments of vegetable origin, which are very thin, are acted upon by boiling water, consisting of colloid cellulose, whereas thicker paper is not affected by the same treatment, undoubtedly owing to a stronger acid being employed in the manufacture of the latter. In both cases colloid cellulose has been produced, but in the second the cellulose has become insoluble. Vegetable parchment seems to consist of ordinary cellulose, the pores of which are filled by colloid cellulose. Amongst the natural products which hitherto have been investigated, none resemble colloid cellulose; pectic bodies, gelatin, &c. distinguishing themselves by essential properties. These bodies are not precipitated by the presence of small quantities of foreign matter, which, however, is the case with colloid cellulose.—O. J. S.

PATENT.

An Improvement in the Manufacture of Rosin Liquor for Paper Makers and others. C. Morfit, London. Eng. Pat. 18,716, December 21, 1888. 6d.

THE patentee uses sodium aluminate as a solvent for rosin in place of the sodium carbonate or hydrate commonly employed. It is stated that the solution thus obtained is not liable to act caustically on the paper, and that the rosin becomes white in the process of preparation, which is as follows:—Six pounds of caustic soda of "72° test" are dissolved in 6 galls. of water heated to 200°—212° F. by open steam; 5 lb. of alumina are added, and the heating and agitation produced by the steam continued until solution is effected, when enough cold water is added to bring the bulk to 10 galls. The clear liquor is drawn off, heated to 200°—202° F. by open steam, 30 lb. of rosin added and the heating and agitation continued until it has dissolved. The liquor thus obtained which is to be called "Comaralyk" is apt to deposit rosin on standing; to obviate this difficulty the solution of sodium aluminate before the addition of the rosin may be diluted with 20 galls. of water, and after the solution of the rosin with a further quantity of 20 galls. of water which must be previously heated to 200°—212° F. This product is to be termed "Lycophil."—B. H.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Report on New Drugs and Fine Chemicals. Merck's Bull. 2 (8), 1889, 61—68.

Amylenhydrate (Kahlbaum) (*Tertiary Amylic Alcohol, Dimethyl-ethyl carbinol*) ($(CH_3)_3(C_2H_5):C.OH$).—This hypnotic possesses a peculiarity shared by several substances of its class, to wit, that its hypnotic action is pure and innocuous, and devoid of accessory or subsequent symptoms when the medicament is of a very high degree of purity; also that the substance has been sometimes erroneously held responsible for untoward effects perceived after its use, but which were altogether due to impurities resulting from inefficient methods of preparation.

The pure carbinol in question is a very mobile colourless liquid, of sp. gr. 0.81, and boiling point $100^\circ C$. When pure it is soluble in 8 parts of water and is miscible with alcohol in all proportions. Its taste is ethereal and yet like camphor, with a cooling, peppermint-like after flavour. For the physiological action of pure Amylenhydrate see the *Therap. Monatshefte* for 1887, July Number, Dr. J. von Mering.

Anemonin is the active principle of *Pulsatilla* (*Anemone P.*). It consists of colourless acicular crystals, melting at $152^\circ C$, very sparingly soluble in water or ether, but easily in warm alcohol. It is a cerebral poison, the lethal action of which proceeds by annihilating the functions of the central nervous system—the effect being preceded and accompanied by spasmodic and paralytic phenomena. This is when large doses are taken. Anemonin cannot be classed as a strong poison. It is useful in bronchitis and asthma.

Monobromide of Gold (Aurous bromide), *Au Br*, forms a yellowish-grey friable mass, insoluble in water. It has been made known as an *Anti-epileptic* of great promise through a treatise of Goubert's (*Journal de Médecine de Bruxelles*, 1889, No. 5). This treatise has been awarded a prize by the Parisian Academy of Sciences. Goubert recommends it as being an epileptic medicament better borne than any other bromine compound known, and it has been used in all varieties of *Hemicrania* and in *Struma ecophthalmica*.

Guaiacol (*Monomethyl catechol*), $C_6H_4(OCH_3)OH$ [1:2] the active principle of wood-tar creosote, is spoken of as the sovereign remedy in *Pulmonary tuberculosis*.

Creosote is, however, a complex substance containing 60–90 per cent. of guaiacol with a remainder composed of the cresols and homologues of other phenols and phenolic ethers. Sahli of Berné in accordance with the tendency of modern medicine to employ *homogeneous substances*, recommended that instead of even the best prepared creosote guaiacol itself should be used. Hence of more recent date guaiacol has been exclusively employed in the treatment of *tuberculosis*. It is necessary then to consider the physical and chemical reactions of pure guaiacol. It is a colourless oily liquid, strongly refractive, with peculiar aromatic odour, and sp. gr. of 1.1171 at $13^\circ C$. It boils at $201^\circ C$, is soluble in 200 parts of water and is miscible with alcohol, ether, and carbon bisulphide. Its alcoholic solution is coloured blue by the addition of a little ferric chloride, whilst a larger addition changes the colour to green. One volume of guaiacol with two of petroleum ether forms a turbid mixture, which remains clear at $13^\circ C$ on addition of six further volumes of the petroleum spirit. One volume of guaiacol with two of carbonate of soda solution yields a clear mixture, soluble in 10 volumes of water and giving a clear colourless solution. One volume of guaiacol with two of potash solution solidifies in a short time to a white crystalline mass.

THE MYDRIATIC ALKALOIDS OF THE SOLANACEÆ.

Bulletin No. 9. 69—76.

A mydriatic drug is a substance capable of producing *Mydriasis*, i.e., dilation of the pupil of the eye.

The mydriatics which have so far gained therapeutic prominence so far are found in plants of the natural order of the *Solanaceæ*, and the active principles in those plants to which the action is due are certain alkaloids existing therein in combination with vegetable acids, and separable therefrom by certain chemical processes. Among the solanaceous mydriatic alkaloids are to be distinguished the class of Homogeneous or simple bases, such as *Atropine*, *Hyosine*, and *Hyoscyamine*, and that of the Heterogeneous, or mixed bases, such as *Daturine*, *Duboisine*, *Syrupy Hyoscyamine*, and *Scopoline*. The latter class comprises natural mixtures of the simple alkaloids of the first class in such ratio of mutual strength as that in which they are found naturally, and present together in various plants, such as *Datura stramonium*, *Duboisia myoporioides*, *Hyoscyamus*, *Scapolia japonica*, &c. To the heterogeneous class likewise probably belongs the newly discovered mydriatic base *Mandragorine* from *Mandragora vernalis*.

The Homogeneous, or simple Mydriatic Alkaloids, so far as they are known, are all possessed of one common empirical formula, $C_{17}H_{23}NO_3$, i.e., they are mutually isomeric, and the chemical distinction between them is based principally on the different forms and behaviour of their double salts with the heavy metals and partly of their fractional derivatives.

Besides the natural solanaceous alkaloids as already named, there is already in wide therapeutic use an artificial mydriatic simple alkaloid, procured synthetically from mandelic acid and tropine (a fractional derivative of atropine); this is—

Homatropine, $C_{16}H_{21}NO_3$. Its formula shows that it is the next lower homologue of atropine, hyoscyne, and hyoscyamine. This close chemical relationship is more than borne out by its physiological similarity to them. The latest chemical researches have established the probability that the three isomerides, atropine, hyoscyne, and hyoscyamine are even more closely related than what the mere condition of *isomerism* would necessitate. With atropine and hyoscyamine this is a settled fact. Whether polymerism is here involved has not yet been ascertained. It has been long known that both atropine and hyoscyamine may be obtained from *Atropa belladonna*, according to the different processes of extraction and isolation employed. Schmidt and Will have moreover established the fact that the hyoscyamine from *Atropa belladonna* may be converted into atropine by keeping it for some time at a temperature above its melting point, or by treating it with a small quantity of alkali.

Notwithstanding, however, the gradual weakening of the bonds connecting these alkaloids by chemistry, the differences hitherto found by physiology are not only fully maintained but even intensified, as the result of recent research.

With atropine, toxic symptoms of the severest kind are liable to arise, but pure hyoscyamine is, according to Gnauck, less toxic than atropine, which it resembles in the general direction of its effects. However a characteristic difference distinguishing it from atropine consists in its action in small doses as a true hypnotic. Hyoscyne likewise gives the effect of atropine and is not followed by the dangerous general symptoms frequently consequent upon treatment with atropine. Hyoscyne is also, like hyoscyamine, an excellent hypnotic. Homatropine, in general direction of effects, corresponds entirely to atropine, but it essentially differs from atropine in the course of its mydriatic effect, which whilst being characterised in its maximal period almost exactly like that of atropine, exhibits a very considerably briefer continuance than the atropine effect.

Atropine.—The pure alkaloid appears in fine, silky, colourless, odourless needles of bitter acid taste. They melt at $113.5^\circ C$, dissolve in 200 parts of cold or 54 parts of boiling water, in $2\frac{1}{2}$ parts of 90 per cent. alcohol or 60 of ether, and are very easily soluble in chloroform and amyl alcohol.

The aqueous solution undergoes rapid change by contact with the air, becoming yellow and acquiring a disagreeable smell, though not losing the toxic character.

The uncombined alkaloid is very little used, the salts, especially the sulphate, being preferred.

Atropine Sulphate ($C_{17}H_{23}NO_3$) $_2 \cdot H_2SO_4$, is colourless and odourless, neutral, easily soluble in alcohol and in water, but less so in ether. It contains 85½ per cent of atropine.

Atropine Valerianate and Atropine Borate are extensively used. The indications and effects are the same as with the sulphate. One individual may be killed by a dose of 0.01 gram of atropine whilst another may recover from the effects of a dose of 0.25 gram, so different is the action in the case of different individuals. The antidotes are emetics such as apomorphine hydrochloride (0.005 to 0.01 gram), chloral hydrate, 3 grms., several times repeated, and also pilocarpine subcutaneously administered, 0.02 gram, several times repeated.

Adonidin.—A glucoside containing 42 per cent. of carbon, 7.5 per cent of hydrogen, and no nitrogen. It is the active principle of *Adonis vernalis*. Opinions as to physiologic action have been hitherto at variance. Gergiejenko of Kasan (Gaz. Lek. 1888, 8, 32) instituted a new series of experiments with it, which show that adonidin acts on cold-blooded animals as a heart poison, whilst in warm-blooded animals it acts toxically on the medulla oblongata.

Adonidin is a hygroscopic, yellowish-white powder, readily soluble in water and in alcohol, insoluble in ether, chloroform, and benzene. When heated above 90° C. it is transformed into a blackish-brown mass.

The tannate is the form in which adonidin is preferably administered.

Eseridine.—It has been stated of this new substance, prepared by Boehringer in a crystalline form, that it partakes only of the therapeutically useful but not of the obnoxious and dangerous properties of eserine. Particular stress has been laid on its possessing only one-sixth the toxic power of eserine. However, Schweber of Prof. Robert's Pharmacological Institute at Dorpat, after a series of experiments, concludes that eseridine possesses no advantages over eserine. The chief drawback to both, and equally shared by them, detracting in fact from the usefulness of the calabar alkaloids generally, is the ready susceptibility of the heart to their action. In short the assertion that eseridine is free from the toxic action of eserine is false. (This Journal, 1889, 413, see *Eserine-Pilocarpine*.)

NEW MERCURY COMPOUNDS.

Bulletin No. 10. 77 to 84.

Soon after the hypodermic method of treatment with mercurial preparations for syphilitic diseases had been amplified, there was shown a desire for a greater choice of mercurial preparations adapted for subcutaneous injection.

Among the mercurial compounds introduced for this purpose, one class is distinguishable by ready solubility in the animal fluids, and consequently for rapid absorption into the system, whilst another is distinguished for slow solubility and for its consequent double mode of action, combining the advantages of acute with those of chronic mercurialisation. Prominent in the latter class are the *Mercurio-phenolide double salts*, which consist of compounds of mercury with the various phenols.

It may be well first to describe the simple mercurio-phenolides which have already been put to therapeutic uses.

I. SIMPLE MERCURIO-PHENOLIDES.

Mercury Phenate (Mercurio-Phenol).—Gamberini first introduced the mercury phenates into therapeutics.

The particular modification of mercury phenate produced as a precipitate by the reaction between solutions of bichloride of mercury and sodium carbonate (phenate) is the one known by the affixed name of Schadeck, its originator. According to the conditions governing the process of precipitation, more or less basic products are obtained, distinguishable by their colours, which vary from greyish-white to yellow and orange. These products are of varying strength of mercury.

Mercurio-Thymol, $C_{10}H_{12}(Hg).OH$ —This has in England been recommended for therapeutic use (*Medical Standard*, 1888, July). It is, like the above-described phenate, a

precipitate, and is similarly obtained from the solutions of sodio-thymol and of mercuric nitrate. Its colour is purplish-green. The formula given is that ascribed by Lallemant (*Ann. de la Chim. et Phys.* 3, 49, 118). It is stated of the basic compound that it lacks permanence.

Mercurio-β-Naphthol is highly praised by E. Bombelon (*Pharm. Zeit.* 1888, 98, 739) for its highly beneficial action, applied externally, in the case of old sores and wounds, eczemas; also internally in typhus. It is a lemon-yellow powder, capable of crystallisation according to Bombelon. It is devoid of odour and taste, and is insoluble in the ordinary solvents. The method of its preparation and its composition are not published.

II. MERCURIO-PHENOLIDE DOUBLE SALTS.

These compound phenolides are distinguished from the various simple phenolides referred to by assuming a clear crystalline form and by their chemical composition, which includes, besides mercury and a phenol, also an organic or inorganic acid as an essential molecular constituent.

Of these compounds the following have been so far introduced:—

Mercury Phenol Acetate.—A well-crystallised salt, appearing in minute colourless needles, collected into spheroidal conglomerations. In other particulars it much resembles the thymol acetate.

Mercury Thymol Acetate.—A very distinctly crystalline salt of constant composition and permanent character; white, odourless, and tasteless.

Mercury Thymol Nitrate and Mercury Thymol Sulphate.—These are similar to the foregoing.

Mercury β-Naphthol Acetate has been recently prepared, and appears as a white crystalline substance, which in its various properties is very much like the thymol acetate and phenol acetate of mercury. (See this Journal, 1889, 566.)

Mercury α-Naphthol Acetate and Mercury Tri-bromophenol Acetate are yellow compounds.

Mercury Resorcinol and Mercury Phloroglucol Acetate have also been prepared. The former of these is yellow. These latter compounds are still undergoing chemical investigation. It can, however, be definitely stated that mercurio thymol acetate has yielded excellent results.

Tertiary Amyl Nitrite (Bertoni's Amylo-nitrous Ether) $C_5H_{11}NO_2$.—This compound was prepared by Bertoni, Professor of Chemistry in Pavia University, as a substitute for ordinary amyl nitrite (*Iso-amylic nitrite*). Its constitution is represented by the formula—

whilst that of ordinary amyl nitrite is—

Tertiary amyl nitrite has a weak camphor-like and not disagreeable odour and a taste of peppermint. It boils at about 30° C. With the addition of a trifle of anhydrous sodium nitrate, it may be preserved undecomposed for a long time.

According to Balp and Broglio (*Bolletino Farmaceutico*, 1888, July, 193), the physiological action of tertiary amyl nitrite is the same in kind as that of iso-amylic nitrite, but somewhat stronger in degree and more enduring. It also admits of larger doses being taken by inhalation without danger, and is altogether safer. Given by inhalation it is followed by about half an hour's sleep. Subcutaneous injections can be made of tertiary amyl nitrite by dissolving it in aqueous glycerol.

Caffeine associated with Hypnotics in Heart Diseases.—The conclusions following the experiments of Schröder, and V. Carello and Carno Pecosaro (*Annali di Chim. e Farmacol.* 1889, April, 255), are that caffeine is best associated with paraldehyde, and that with organic heart disease no chloral hydrate must be used, whilst paraldehyde is admissible, being much milder in its action on the heart.

Santonin-orime is stated to be a non-toxic substitute for santonin. The oxime in question was prepared by Cannizaro

by the action of hydroxylamine hydrochloride on an alkaline solution of santonin according to the equation—

Thus, the oxygen atom of the ketone group in the santonin enters the hydroxylamine, splitting off therefrom a molecule of water and thus forming as a remnant the oxime-group.

According to Coppola (*Répertoire de Pharm.* 1889, 45, 257), santonin-oxime is a well crystallised substance, and is far less easily soluble in the animal fluids than santonin. Whilst being non-toxic, it is stated to be just as efficacious an *Anthelmintic* (killer or remover of intestinal worms) as santonin when given in about the threefold dose of the latter. This fact is explained thus. The vermifugal action of santonin is not at all dependent on absorption of the medicament by the human organism, because the action is to be exercised directly on the intestinal worms during the passage of the undissolved substance through the intestinal canal. But santonin sometimes occasions toxic symptoms in the patient by first inducing intestinal catarrh accompanied by an inordinately large production of lactic acid, which then favours the solution of the santonin and its absorption into the organism. Santonin-oxime, on the other hand, by virtue of its slight solubility and absorbability offers the greatest likelihood among all santonin preparations of accomplishing the removal of the intestinal parasites without injury to the patient.

On some New Artificial Medicinal Compounds. Cocaine and Derivatives, Narceine, Hydrazine, and Musk Substitute. Dingl. Polyt. J. 273, 522—528.

In the Coca leaves there are, besides cocaine, some other amorphous alkaloids which Liebermann has succeeded in converting into Cocaine by first treating them with hydrochloric acid, sp. gr. 1.1—1.2, thus forming Ecgonine, and converting this by benzoyl chloride or benzoic anhydride into cocaine. Böhringer and Söhne prepare cocaine from the methyl- or ethyl-ecgonine ethers by treating them with benzoyl chloride.

Phthalyl-di-ecgonine methylether—

is prepared by the action of orthophthalylchloride on ecgoninemethylether.

Isovaleryl-ecgonine methylether, $\text{C}_3\text{H}_7\text{O} \cdot \text{C}_{10}\text{H}_{16}\text{NO}_3$, was obtained by the action of isovalerylchloride on ecgonine-methylether.

Cocethyline or Homococaine is Benzoyl-ecgonine ethylether.

Phenacetyl-ecgonine methylether—

was prepared by the mutual action of equal parts of phenacetylchloride and ecgonine methylether when heated in a flask at 100° for four hours. The melted mass is poured into water, and the ether precipitated with carbonate of soda.

Oxidation of benzoyl-ecgonine and ecgonine with potassium permanganate produce *Cocylbenzoylhydroxybenzoic acid*, $\text{C}_{15}\text{H}_{17}\text{NO}_4$, melting point 230° C. in the case of the benzoyl compound, and *Cocylhydroxyacetic acid*, $\text{C}_8\text{H}_{13}\text{NO}_3$, melting point about 233° C., from ecgonine.

Methyliodide and methylbromide form with cocaine compounds $\text{C}_{17}\text{H}_{21}\text{NO}_3\text{CH}_3\text{I}$, and $\text{C}_{17}\text{H}_{21}\text{NO}_3\text{CH}_3\text{Br}$.

W. Roser prepares *Narceine* from narcotine-methylchloride by treating it in aqueous solution with caustic soda—

Homonarcine is prepared in the same way from narcotine ethylchloride.

Ph. Curtius prepares hydrazine compounds from triazotic-acetic acid by treating it with concentrated acids—

To obtain all the hydrazine even from dilute solutions, they are treated with benzaldehyde, and the insoluble benzylidene hydrazine is reconverted into hydrazine by boiling with dilute sulphuric acid.

Musk.—To form a cheap Musk, A. Baur proceeds in the following way: Toluene is mixed with the halogen compounds of Butane, and the mixture is boiled in a reversed condenser with aluminium chloride. The product of the reaction is distilled with steam. The portion passing over between 170° and 200° C. is treated with fuming nitric and sulphuric acids. The product thus prepared is recrystallised from alcohol and water. The yellowish-white crystals are dissolved in alcohol and a trace of ammonia or ammonium carbonate is added. This liquid has an odour similar to that of musk.—A. L.

Syntheses in the Oxazine Series. L. Knorr. Ber. 22, 2081—2099.

THE colouring matters derived from the chromogen—

are called oxazines. Widman defines oxazines or azoxines as bodies containing a ring of six atoms: one nitrogen atom, one oxygen atom, and four carbon atoms, which are joined by eight bonds of affinity.

This class of bodies is of greater interest, since the author's studies on morphine have rendered it probable that this important base and other alkaloids may be considered as oxazines. The formula which explains the reactions of morphine best is—

This represents morphine as a derivative of the hypothetical base—

which bears the same relations to the simplest oxazine—

as piperidine bears to pyridine. The experiments to produce such reductions have proved successful, and a base has been prepared—

called by the author *morpholine*. This compound was prepared from dihydroxyethylamine—

by heating it with hydrochloric acid in a sealed tube at 160° C., the product of the reaction being boiled with caustic alkali. The reaction proceeds in two phases—

In the same way methylmorpholine and phenylmorpholine were prepared from dihydroxyethylmethylamine and dihydroxyethylaniline.

Hydroxyethylamidophenol—

or, better, hydroxyethylanisidine—

produces a base—

which the author terms phenomorpholine.

Of its derivatives, only methylphenomorpholine was prepared from Mulhauser's methylamidine. Wurtz's method by the action of chlorhydrin on the amines was used for the preparation of the alcohol bases. The following table will serve as an illustration of the different steps leading from the amines to the morpholines.

Methylamine.	Aniline.	<i>o</i> -Amidophenol.	<i>o</i> -Anisidine.	Methylanisidine.
$(\text{CH}_3) \cdot \text{N} \begin{array}{l} \text{H} \\ \text{H} \end{array}$	$(\text{C}_6\text{H}_5) \cdot \text{N} \begin{array}{l} \text{H} \\ \text{H} \end{array}$			

Converted by ethylene chlorhydrin into—

Hydroxymethylamine.	Hydroxyethylaniline.	Hydroxyethyl- <i>o</i> -amidophenol.	Hydroxyethylmethylanisidine.
$(\text{CH}_3) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \\ \text{H} \end{array}$	$(\text{C}_6\text{H}_5) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \\ \text{H} \end{array}$		
Dihydroxyethylmethylamine.	Dihydroxyethylaniline.	Hydroxyethyl- <i>o</i> -anisidine.	
$(\text{CH}_3) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \\ \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \end{array}$	$(\text{C}_6\text{H}_5) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \\ \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \end{array}$		

Heating with hydrochloric acid produces

Chloro-ethylhydroxyethylmethylamine.	Chloro-ethylhydroxyethylaniline.	Chloro-ethyl- <i>o</i> -amidophenol.	Chloro-ethylmethylanidophenol.
$(\text{CH}_3) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \cdot \text{Cl} \\ \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \end{array}$	$(\text{C}_6\text{H}_5) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \cdot \text{Cl} \\ \text{CH}_2 \cdot \text{CH}_2 \cdot \text{OH} \end{array}$		

Which on boiling with caustic alkali yield—

Methylmorpholine.	Phenylmorpholine.	Phenomorpholine.	Methylphenomorpholine.
$(\text{CH}_3) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH}_2 \end{array} \text{O}$	$(\text{C}_6\text{H}_5) \cdot \text{N} \begin{array}{l} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH}_2 \end{array} \text{O}$		

Hydroxyethylmethylamine was obtained by heating equivalent quantities of methylamine and ethylene chlorhydrin in aqueous solution for 12–24 hours at 110° C. On distillation with solid caustic potash, first, methylamine, and, later, hydroxyethylmethylamine distil over. Yield about 80 per cent. The base is easily soluble in water, alcohol, and ether, and boils at 130°–140° C.

Dihydroxyethylmethylamine.—Equivalent quantities of chlorhydrin and hydroxyethylmethylamine are heated in aqueous solution for several hours at 120° C. This is a thick oil, boiling at 240°–265° C., and soluble in water. With methyl iodide it forms the *iodide of dihydroxydimethylammonium hydroxide*. On evaporation of the aqueous solution of this iodide, decomposition ensues, hydroxyethyl-dimethylamine being formed.

1-Methylmorpholine is obtained by heating dihydroxy-methylamine with fuming hydrochloric acid for 12 hours at 160° C. It is easily soluble in water, alcohol, and ether, boils at 117° C., and combines with methyl iodide, the compound, on treatment with moist silver oxide, yielding methylmorpholinemethylhydroxide. The number 1, assigned in the above formula refers to the position of the CH₂ according to Knorr's scheme—

Hydroxyethylaniline boils at 286° C., and possesses strong reducing power.

Dihydroxyethylaniline boils above 350° C.

Phenylmorpholine boils at 270° C. and melts at 53° C., is insoluble in water, easily soluble in alcohol and ether, and volatilises with steam.

Hydroxyethyl-o-amidophenol boils at 290°–310° C.

Hydroxyethyl-o-anisidine.—Boiling point 295° C. With difficulty soluble in water, with ease in ordinary solvents, is a strong reducing agent.

Phenomorpholine boils at 268° C.

Hydroxyethylmethyl-o-anisidine boils at 290° C.

Methylphenomorpholine boils at 261° C., is volatile with steam, and is coloured intensely red by ferric chloride and nitrous acid.—A. L.

Hydrastine. M. Freund and S. Lachmann. Ber. 22, 2322–2328.

In a former paper (this Journal, 1889, 637) one of the authors ascribed to hydrastinine acid the formula C₁₁H₁₁NO₅. Further experiments with a purified sample of acid show that the formula should be altered to C₁₁H₉NO₆. On oxidation with nitric or chromic acid, hydrastinine acid is converted into a substance having the formula C₁₀H₇NO₄. It crystallises from glacial acetic acid in large white needles melting at 233° C. It is soluble in warm strong caustic potash solution, from which it is reprecipitated by acids. When boiled with potash it is first converted into a body of the formula C₁₀H₁₁NO₆, and then into an acid containing no nitrogen and having the composition C₉H₆O₆, methylamine being given off. The authors propose to name the latter body hydrastic acid. It crystallises in colourless needles, melting at 175° C. It is dibasic, and easily forms an anhydride on heating. Strong nitric acid converts it into a nitro-derivative, melting at 101°, and having the formula C₇H₄N₂O₆.

This body is identical with the methylene-ether of di-nitrocatechol, which Hesse and Jobst (Ann. Chem. Pharm. 199, 75) prepared by the action of nitric acid on piperonylic acid. Piperonylic acid differs from hydrastic acid by having one CO₂ group less. Hydrastic acid may, therefore, be considered to be derived from piperonylic acid by the substitution of a COOH group for a hydrogen atom. The two COOH groups of hydrastic acid are probably adjacent,

since the acid so readily forms an anhydride. The following two constitutional formulae are therefore possible for hydrastic acid:—

The nature of hydrastic acid being known it is easy to arrive at that of the other derivatives of hydrastine. The substance C₁₀H₇NO₄ from which hydrastic acid is derived is the methylimide of hydrastic acid—

whilst the intermediate body is the acid methylamine salt of hydrastic acid, CH₂ : O₂ : C₆H₂ : (COOH)COOH, NH₂.CH₃.

For hydrastinine acid three formulae are possible, but the authors give preference to the following formula:—

Oxyhydrastinine has the formula—

Oxyhydrastinine is the first oxidation product of hydrastinine and differs from it in having two atoms of hydrogen less. Hydrastinine behaves like an aldehyde, and in another paper it is shown to be a secondary base.

Under these circumstances only one formula can be ascribed to it, viz.:—

Hydrastinine may therefore be looked upon as piperonal, in which one of the hydrogens, occupying the ortho position towards the aldehyde group, has been replaced by the group CH₂.CH₂.NH.CH₃.—H. T. P.

Hydrastine. M. Freund. Ber. 22, 2329–2339.

As the result of his experiments with cotarnine, Roser ascribed to it the formula—

which is analogous to that of hydrastinine determined by the author and S. Lachmann (see previous abstract) by means of quite a different line of research. In the present paper the author describes the results of his experiments with hydrastinine, conducted in a similar manner to those of Roser with cotarnine. Hydrastinine, when heated with an excess of methyl iodide, yields hydrastinine hydriodide, and another substance crystallising in pale yellow needles of the following composition, C₁₃H₁₃NO₃1. The crystals melt at 267° C. This body is evidently formed from hydrastinine by the substitution of a methyl group for a hydrogen atom, and the further addition of a molecule of methyl iodide. Hydrastinine thus appears to be a secondary base. The formation of hydrastinine acid and the reactions of the latter (see previous paper) conclusively prove the NH group to be combined with methyl. The presence of an aldehyde group in hydrastinine is shown by its behaviour with hydroxylamine (this Journal, 1889, 412), and by other considerations (this Journal, 1887, 381, 449, and 641). The constitution of the substance C₁₃H₁₃NO₃1 is therefore the following:—

If the group (C₁₀H₉O₃) be called *hydrastyl*, then the above compound would be trimethylhydrastylammonium iodide. It yields on treatment with hydroxylamine hydrochloride, an oxime crystallising in pale yellow needles, which are decomposed at 250° C. Its composition is—

It is readily soluble in alkaline solutions, from which it is reprecipitated by acids. When warmed in aqueous alkaline solution, trimethylhydrastylammonium iodide is easily decomposed, methylamine being given off. Oily drops separate at the same time, which solidify on cooling. This new body crystallises from alcohol in yellowish rhombic plates, melting at 78°–79° C. It is insoluble in cold, slightly soluble in hot water, and readily soluble in alcohol, ether, and chloroform. When heated with water it volatilises with

the steam. Its composition is $C_{10}H_8O_3$. The author proposes to call it *hydrastal*. With phenylhydrazine it gives a crystalline body melting at $103-104^\circ$. Hydrastal oxidised in alkaline solution by potassium permanganate yields crystals melting at 158° . This substance is neutral in character. The author found the mother-liquor from the above crystals to contain a small quantity of an acid melting approximately at $170^\circ C$, but sufficient for analysis could not be obtained, yet he believes it to be identical with hydrastinic acid. The latter has the following formula: $C_7H_4O_2(COOH)_2$. The formula for hydrastinine must therefore be—

which is identical with that obtained by the author in conjunction with Lachmann. Cotarnine may be looked upon as hydrastinine in which one of the hydrogen atoms of the benzene nucleus has been replaced by methoxyl—

Four isomeric methoxyl derivatives of this formula are possible; which one corresponds to cotarnine has not been decided.

The salts of hydrastinine, like those of cotarnine, contain one molecule of water less than the free base. This can be explained by supposing that a ring formation takes place, thus:—

The salts of hydrastinine and cotarnine are therefore derivatives of isoquinoline, in which the pyridine nucleus has been reduced. This supposition explains the behaviour of hydrastinine with reducing and oxidising agents as well as with caustic alkalis. The decomposition products of hydrastine, narcotine, and papaverine, are all very closely related to isoquinoline, and therefore these substances themselves bear a close relationship to that body. It seems, therefore, that this body probably plays an important part as the root-substance of nitrogenous organic compounds found in the vegetable kingdom. Hydrastine and narcotine are formed from opianic acid, and hydrastinine and cotarnine respectively. The three last bodies all contain an aldehyde group; whilst in the alkaloids themselves an aldehyde group cannot be directly detected. This may be explained by assuming the existence of a group, $-C \equiv C-$, in the alkaloids. The formula of hydrastine would then be—

When hydrastinine dissolved in methyl alcohol is treated with methyl iodide, a crystalline body is formed, melting at $230^\circ-232^\circ$. It is isomeric with the trimethylhydrastylammonium iodide which melts at $267^\circ C$. It is not decomposed by alkalis. The author names it *hydrastinmethinnethyl iodide*. Digestion with methyl iodide does not convert it into the higher melting variety. Its constitutional formula has not yet been fully decided upon; but it is probably formed in the following manner:—

The tertiary base thus produced at once combines with a molecule of methyl iodide to form the body $C_{13}H_{13}NO_3I$, whilst the hydriodic acid liberated combines with unattacked hydrastinine.—H. T. P.

Investigations on Apiol. G. Ciamician and P. Silber. Ber. 22, 2481—2490.

In a previous communication the authors described a phenol derivative obtained by the action of alcoholic potash on apioleic acid which they regarded as the dimethylether of a tetrahydroxybenzene, $C_6H_2(OH)_2(OCH_3)_2$ (this Journal, 1888, 396 and 583). The isolation of the tetrahydroxybenzene, the mother substance of apiol, has not been effected, but there is no doubt from these investigations that the above constitution of apiol is correct.

The name of "*Apionol*" is suggested for the mother substance of apiol, whence that of dimethylapionol for the latter. The yield of apiol from apioleic acid according to the method already described (*loc cit.*) amounts to 2 grms. from 7.5 grms. of the acid. The product melts at $105^\circ-106^\circ$, and boils at 298° . In addition to the reactions previously described dimethylapionol when treated with ferrous sulphate remains unchanged at first, but after a time yields a blue colouration; lead acetate (neutral) gives a gelatinous precipitate which turns brown on standing, and silver nitrate gives a finely crystalline precipitate which blackens immediately. If a crystal of dimethylapionol be dissolved on a watch glass in sulphuric acid (conc.), the solution first becomes yellow, then red, and on warming, violet. To show the presence of four hydroxyl groups in apionol the authors have prepared tetramethylapionol, and dimethyldiacetylapionol from dimethylapionol by the usual methods. The former melts at 81° , is slightly soluble in cold water, readily in alcohol, ether, &c.; it gives a yellow colouration with nitric acid and a brown colouration with sulphuric acid (conc.) on warming. The latter can be crystallised from alcohol, and melts at 144° ; it is less soluble in water than the former, and turns first yellow, then brown when warmed with strong sulphuric acid.

Apiolealdehyde (this Journal 1888, 584) can be condensed with benzaldehyde with the formation of apionacrylic acid, according to Perkin's reaction. The resulting compound, $C_6H(O_2 \cdot CH_2 \cdot) (OCH_3)_2 (CH : CH \cdot CO \cdot OH)$ forms small yellow needles which melt at 196° ; it is only slightly soluble in water and in ether, readily soluble in alcohol. The salts of the alkalis and of magnesia are soluble, those of zinc, nickel, cobalt, iron, copper, silver, lead and mercury are insoluble. The barium and calcium salts dissolve in hot water.

By substituting benzaldehyde by propionaldehyde in the above reaction an apionerotic acid is obtained, the exact constitution of which has not yet been decided. It forms yellow needles which melt at 209° ; in water it is practically insoluble, but dissolves in hot alcohol or hot ether. Of the salts, those of magnesium, calcium, and barium dissolve in hot water, those of silver, zinc, copper, nickel, cobalt and iron are thrown down as precipitates from solutions of the alkaline salts which are readily soluble in water.

When a solution of apioleic acid in glacial acetic acid is added to well-cooled nitric acid of sp. gr. 1.40 a nitro-compound results which, crystallised from aqueous alcohol, forms yellow needles melting at $117^\circ-118^\circ$. This body, which appears to be a dinitro-apion ($C_6(NO_2)_2(OCH_3)_2(O_2CH_2)$) is insoluble in water, alkalis, and the alkaline carbonates, but dissolves in ether, alcohol, and acetic acid. It may be identical with the nitro compound obtained by Ginsberg from isapiol (this Journal, 1888, 399).

—C. A. K.

On the Natural Occurrence of Cinnamylcocaine in Coca Leaves. F. Giessel. Pharm. Zeit. 34, 516.

CINNAMYLCOCAINE, which has already been prepared synthetically, has been found by the author as a natural constituent of the coca leaves, and he has also isolated it. The properties of the natural body agree with those of the synthetically

prepared cinnamyleocaine. It melts at 121° , crystallises well, and is decomposed by permanganate with formation of oil of bitter almonds. It is quantitatively split up by hydrochloric acid into cinnamic acid and eegonine.—W. M.

On Crystallised Tanghinin Extracted from the Tanghinia Venenifera of Madagascar. Arnaud. *Compt. Rend.* 108, 1255—1258.

TANGHININ, the celebrated judicial poison used by the inhabitants of Madagascar, has been examined by the author. It was known that the toxic principle was contained in the almonds of the *Tanghinia venenifera*, belonging to the family of the Apocynaceae. The almonds contain about 75 per cent. of fatty matter which could not be got rid of by simple pressing. By treating with bisulphide of carbon, however, which does not take up the tanghinin, the fat was extracted. Subsequent boiling with strong alcohol, and evaporation, yielded a crystalline substance of powerful toxic properties. It has a strong action upon the heart, resembling strophanthin and ouabaine (this *Journal*, 1889, 211; also 1888, 765), having, however, a more general convulsive action than these bodies. Tanghinin forms colourless, rhombic, anhydrous crystals, which melt at 182° C., and are very difficultly soluble in water, but easily in strong alcohol. It is levo-rotatory, and has the following composition:—

Carbon.....	65.79	65.70
Hydrogen.....	8.16	8.22
Oxygen.....	26.05	26.08
	100.00	100.00

As it contains no nitrogen, tanghinin is neither an alkaloid nor is it a glucoside. The author intends to prepare derivatives, in order to determine its chemical constitution.

—O. J. S.

Camphor and Borneol of Rosemary. New Method of Separating Camphor and Borneol. A. Haller. *Compt. Rend.* 108, 1308—1310.

THE camphor obtained from rosemary is a mixture of dextro- and levo-rotatory camphor with dextro- and levo-rotatory borneol, separable by the following process, which is applicable to all similar mixtures:—

The crude camphor is deposited on cooling from that portion of the essential oil of rosemary which distils over above 190° C. It is pressed between filter paper, and purified by sublimation with lime, then triturated with $\frac{2}{3}$ of its weight of succinic acid, and heated in a matrass to 140° C. for 48 hours. The product separates into two layers, which both solidify on cooling and, on treatment with ether, the camphor and the acid succinate of camphor are dissolved out, leaving the excess of succinic acid undissolved. On agitating the ethereal solution with one of sodium carbonate, the acid succinate of borneol is dissolved out, leaving the camphor in solution. The carbonate of soda solution is washed by shaking with ether, then acidulated, and again agitated with ether, and on evaporating this ethereal solution, the acid succinate is obtained pure, as an unctuous mass. On saponifying this with boiling sodium hydrate, and purifying the liberated camphol by sublimation or crystallisation from petroleum spirit, hexagonal plates, resembling those of ordinary borneol, are obtained, smelling of camphor and pepper, and melting at 207.5° C. This camphol yields, on conversion, a camphor melting at 178.65° , with rotatory power $(\alpha)_D = -29.60$, and this yields two monobromo-derivatives melting at 76° and 51° , with rotatory powers of $(\alpha)_D = -124$ and $(\alpha)_D = 0$ respectively. The original camphor freed from borneol has a rotatory power of $(\alpha)_D = 21.7$, unaltered after treatment with nitric acid.

—J. M. H. M.

On the Acetates and Benzoates of Active and Racemic Camphor, and a Method of Preparing pure Dextro-Rotatory Borneol identical with Borneol of Dryobalanops. M. A. Haller. *Compt. Rend.* 109, 29—31.

VARIOUS acetates of camphor have been obtained, but all these compounds had varying rotatory powers and boiling

points, only the acetate prepared by de Mongolfier, from the borneol of Dryobalanops was a uniform body. This compound melted at 24° C., distilled at 226° — 227° , and had a rotatory coefficient of $(\alpha)_D = +32^{\circ}$. The author continues these investigations on dextro- and levo-rotatory camphors $(\alpha)_D = +37^{\circ} 33'$ and $+37^{\circ} 77'$. By heating borneol with an excess of glacial acetic acid to 200° , or with the anhydride at 100° , the ether was obtained, distilling between 210° — 226° C. On cooling, almost the whole of the mass crystallised, leaving a small quantity, very likely some of the inactive compound. The crystals boil at 225° — 226° C. By mixing equal parts of the levo- and dextro-rotatory acetates, the racemic acetate is obtained, which does not even crystallise at -17° . The dextro- as well as the levo-rotatory acetates have a rotatory power of $+ \text{ and } -44.5$. Camphor, on reduction, yields a mixture of the two isomeric borneols. From the above-mentioned acetyl compounds the acetate of the dextro-borneol $(\alpha)_D = +44^{\circ} 58'$ was prepared, and this, on saponification, yielded the free borneol $\alpha_D = +37^{\circ} 63'$. The author also prepared the benzoyl compounds by treating borneol with benzoyl-chloride, a colourless oil being obtained, which crystallised after standing some time during the winter months. Both the dextro- and levo-compounds melt at 25.5° C. and have a rotatory power of $\alpha_D = + \text{ and } -44^{\circ}$. The racemic melts at 20° C.—O. J. S.

On Recent Improvements in the Manufacture of Chloroform. S. P. Sadtler. *The Pharmaceutical Era*, 1889, 376—378.

THE old process of manufacture of chloroform by the action of bleaching powder upon alcohol has given way to what is now termed the "acetone" process. This method is based upon Liebig's discovery of 1832, but was not carried out practically on account of the difficulty of preparing pure acetone cheaply, and also because it was considered that only 33 per cent. of the acetone could be converted into chloroform. Now that acetone is made on a large scale, and of extreme purity, and it has been shown that it is the richest chloroform-yielding substance known (206 per cent. by theory and 200 per cent. in practice, at times), the case assumes a different aspect.

The raw material is the "gray acetate of lime" which is freed both from moisture and tarry matter by careful roasting before submitting it to distillation. The roasting forming the subject of U.S. Pat. by G. Rumpf, is carried out in a series of three slightly-inclined cylindrical retorts (Fig. 1) in which the material is continually pushed forward

Fig. 1.

by revolving blades. The acetate of lime is dropped in at *a* and leaves the furnace at *g*. At *e* and *f* are connexions with the flue through which the moisture and tarry matter can pass out. A second patent refers to the method of distilling the roasted gray acetate. Here, to secure a maximum yield of acetone, the points to be attained are uniformity of temperature throughout the whole mass and slow heating to not over 300° C.

Fig. 2.

By means of stirring the mass with an agitator and admitting free steam in case of any undesirable rise of temperature, a uniformity of temperature may be secured. Fig. 2 shows form of a retort in which this is effected. It will be seen mechanical agitation is provided for by the paddles which rotate round the vertical axis. Steam is admitted by one of the openings above, while the products of distillation pass off by another outlet in the top of the still. The acetone thus obtained is redistilled and rectified till it shows 99° or 100° by alcoholometer.

A third patent of G. Rumpf relates to the process and form of apparatus for most successfully carrying out the chloroform manufacture. In order to obtain the full yield of chloroform it is necessary to take a much larger proportion of chloride of lime than given in Watts' Dictionary of Chemistry, I., page 918, 100 lb. of bleaching powder (35 per cent.) being the necessary quantity for 58 lb. of acetone. The yield will be from 150—180 per cent. of the weight of the acetone employed instead of about 33 per cent. The construction of still and connexions are shown in Fig. 3. The still having been charged with water and the bleaching powder introduced, the manhole *c* is closed with cement.

Fig. 3.

The agitation having been started, the acetone previously diluted is pumped in at *i*. The chloroform which is thus produced distils spontaneously from the delivery tube *d*, passes through the condenser *e*, and is collected under water at *f*. When the delivery of chloroform begins to slacken, steam is injected which heats up the mixture and drives over the remainder of the chloroform. The contents of the still, which consist of very dilute calcium acetate mixed with calcium hydrate and calcium chloride are discharged through *K*.

The reaction for this production of chloroform seems to be—

Theory would require a yield of 206 parts of chloroform—in practice 180 parts are usually obtained—although 200 parts have actually been the result at times.

The chloroform thus obtained is quite free from the chlorinated side products which often accompany the chloroform made from alcohol. It is nevertheless purified by treatment with sulphuric acid and careful washing, and is then brought exactly to the U.S. Pharmacopæia standard.

—O. J. S.

PATENT.

A Portable Receiver to retain Volatile Liquids while allowing of the Escape of their Vapours. W. H. Beaeb, Bridgnorth. Eng. Pat. 18,757, December 22, 1888. 6d.

This invention consists of a metal cylinder having tubes projecting axially within it and terminating a short distance from each other. The cylinder is charged with liquid less than half its capacity, and can thus be held in any position without permitting the fluid to escape. Suitable means are provided at each end for attaching apparatus when administering a local anæsthetic. When not in use the orifices at either end are closed by screw plugs. The drawing shows the instrument as adapted to a "Paquelin thermo-cauter." A modification of the apparatus for the purpose of general anæsthesia is also shown. There are four claims.—E. S.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENTS.

Improvements in and relating to Blasting Cartridges. J. C. Butterfield and T. C. Batchelor, London. Eng. Pat. 15,160, October 22, 1888. 8d.

The object of this invention is to make a tight or waterproof cartridge. The cartridge case is made preferably of metal, and is provided at one end with a stuffing-box through which the fuse passes.—C. N. H.

Improvements in Explosive Compounds. J. Sayers, Stevenston. Eng. Pat. 17,212, November 27, 1888. 4d.

The object of this invention is to form explosive compounds which are inert under ordinary conditions. In carrying out this invention, nitrobenzene, dinitrobenzene or other nitro-derivatives of hydrocarbons are mixed with suitable proportions of nitrates and gelatinised by means of from 2 per cent. to 10 per cent. gun-cotton.—C. N. H.

An Improvement connected with Explosive Shells. W. S. Snipson, London. Eng. Pat. 17,772, December 5, 1888. 6d.

This invention relates to the employment of highly compressed gases or fluids within the chamber of a shell already charged with powder, "their combined action when ignited producing great internal pressure and the development of high explosive properties."—C. N. H.

Improvements in Explosives. G. Trench, Faversham.
Eng. Pat. 18,241, December 13, 1888. 4d.

THE object of this invention is to overcome the non-explosive character of "Roburite" and similar explosives when compressed.

In carrying out this invention nitro-cellulose is added to above class of explosives, the mixture detonating readily even when strongly compressed.—C. N. H.

Improvements relating to the Manufacture of Explosives, and to Apparatus therefor. H. S. Maxim, Westminster.
Eng. Pat. 18,663, December 20, 1888. 8d.

THIS invention relates to apparatus for the recovery of the solvents used in the production of explosive material by the treatment of gun-cotton with acetone, ether, &c. Drawings accompany the specification.—C. N. H.

Improvements in the Manufacture of Explosive Compounds.
W. E. Liardet, Balmain, New South Wales. Eng. Pat. 12,427, August 6, 1889. 4d.

THIS invention relates to a process for the manufacture of an explosive compound in which the elements of danger usually attending such manufacture are avoided, the explosive compound thus produced being absolutely safe in the hands of inexperienced persons. In carrying out this invention, picric acid is dissolved in half its weight of boiling glycerin, to this is added a certain proportion of ground cedar or other suitable wood and nitrate of potash.—C. N. H.

A New or Improved Manufacture of Matches of the Vesta type. J. G. Gomez, Navarre, and P. Franco, Saragossa, Spain. Eng. Pat. 14,362, September 11, 1889. 4d.

THIS invention relates to the substitution of specially treated cardboard for paraffined cotton as a base for vesta matches. In carrying out the invention the cardboard is cut into convenient strips and immersed in a melted mixture of 4 kilos. of "colophane," 1 kilo. stearin, to which is added 200 grms. of zinc white, until impregnated.—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

Self-Regulating Apparatus for Generating Gases from Liquids. J. Thiele. *Annalen*, 253, 242–246.

FOR the generation of gases by the reaction of two liquids on one another, the author employs the following apparatus, which in its simplest form consists of a three-necked Woulff's bottle, on the bottom of which lies a layer of mercury about 1 cm. deep.

One neck holds a funnel tube, the funnel bulb being large enough to contain a sufficient supply of one of the liquids, the other end of the tube is drawn out to a point which just dips below the mercury. The second neck holds a gas delivery tube provided with a stop-cock, and the third neck has a safety tube, closed with mercury.

If hydrochloric acid gas be wanted, the bottle is half filled with concentrated hydrochloric acid and concentrated sulphuric acid is placed in the funnel. On opening the cock of the gas delivery tube, the sulphuric acid rises through the mercury in a fine stream, and occasions a uniform evolution of gas, which can be easily regulated by the cock. When the cock is shut, mercury is forced into the funnel tube, the liquids are thus separated, and in a short time the evolution of gas ceases.

To produce sulphurous acid the bottle is filled with a concentrated solution of bisulphite of soda, and concentrated sulphuric acid is added by the funnel as before. This

apparatus has the two disadvantages that it requires a considerable quantity of mercury, and also cannot be used when the reacting liquids attack mercury.

These, however, are overcome when the mercury is contained in the funnel tube, as shown in the wood-cuts. The small bulb *a* should hold from 6–8 cc. The solution in the bottle being saturated with gas, the apparatus should not be left exposed to the sun's rays, or other source of heat, after having been used.

Nitric oxide may be readily prepared in the above apparatus by filling the bottle with a hydrochloric acid solution of chloride or sulphate of iron, and the bulb tube with a concentrated sodium nitrite solution—

If perfectly pure nitric oxide be desired, as the nitrite frequently contains carbonate, the carbonic acid may be removed by previously treating the nitrite solution with calcium chloride.—W. M.

Determination of Nitrates in Potable Waters. S. Rideal.
Chem. News, 60, 261.

THE author has compared the "phenol sulphuric acid" method with that recently described by S. C. Hooker (this *Journal*, 1889, 569) based on the green colour produced when nitric acid is added to carbazol.

The solutions required are (a) standard potassium nitrate solution containing 0.7215 gm. of the pure crystallised salt in a litre of water; 1 cc. = 0.0001 gm. of nitrogen; (b) phenol sulphuric acid solution prepared by dissolving 15 grms. of phenol in 92.5 cc. of pure sulphuric acid diluted with 7.5 cc. of water.

Pure strong redistilled sulphuric acid and dilute ammonia solution are also required.

The process adopted was as follows:—A known volume of the water is evaporated to dryness. To the dry residue 1 cc. of the phenol sulphuric acid is added, and then 1 cc. of pure water and three drops of strong sulphuric acid, and the mixture is gently warmed. The contents of the dish are then diluted to about 25 cc. and ammonia added in slight excess. The solution is poured into a narrow Nessler tube (14 in. by 1 in.), the dish washed, and the washings added to the liquid in the tube, and the whole diluted to the 100 cc. mark. The colour of the solution is roughly judged, and is then imitated by repeating the operation with the standard potassium nitrate solution.

In the carbazol method the standard potassium nitrate solution and pure sulphuric acid are also required as well as the following special reagents:—

(a). Silver sulphate solution containing 4.3945 grms. per litre or one in which 1 cc. will precipitate 1 part of chlorine per 100,000 from 100 cc. of water.

(b). Aluminium sulphate solution free from chlorides and iron, 5 grms. per litre.

(c). Carbazol solution.—0.6 grm. carbazol is dissolved in 100 cc. of glacial acetic acid. For use, 1 cc. of this solution is mixed with 15 cc. of pure redistilled sulphuric acid.

(d). A series of solutions containing 0.03, 0.05, 0.07, &c., parts of nitrogen per 100,000 from the standard nitrate solution by diluting with water. The process is as follows:—To 100 cc. of the water, the amount in which of chlorides has first been ascertained, sufficient of the silver sulphate solution is added to precipitate all the chlorides. To this solution, 2 cc. of the aluminium sulphate solution is added, and the whole made up to a convenient bulk, 110 cc. in the case of waters containing 1 to 6 parts of chlorine per 100,000. The solution is then filtered, and 2 cc. of this filtrate are then taken for the nitrate estimation. To the 2 cc. of the filtered water contained in a test-tube, 4 cc. concentrated sulphuric acid are added, and the mixture well cooled. 1 cc. of the carbazol solution in sulphuric acid is then added, and a bright green colour appears in a few moments if nitrates are present. The amount of nitrate is roughly gauged from the colour produced, and 2 cc. of the standard nitrate solution, considered to be equal to it, is placed in a second test-tube, and the operation repeated with it and a fresh 2 cc. of the water under examination at the same time. If the tints are not similar a fresh comparison must be made, and in every case it is necessary to repeat the operation with a fresh quantity of the water, so that the colours may be developed as nearly as possible simultaneously. The two processes give very concordant results.

The Application of Double Salts of Pyrophosphoric Acid to the Electrolytic Determination and Separation of Metals. A. Brand. *Zeits. Anal. Chem.* **28**, 581—605.

ALKALINE phosphates added to a neutral aqueous solution of a metallic salt yield in most cases a precipitate insoluble in excess of the precipitant, whilst pyrophosphate of sodium or of ammonium forms a precipitate more or less soluble in excess, a double pyrophosphate resulting. Acid sodium pyrophosphate behaves similarly and some freshly precipitated phosphates are dissolved by the alkaline pyrophosphates. The alkaline pyrophosphates and also the double salts have an alkaline reaction, and when these double pyrophosphates are electrolysed the heavy metal separates out and free pyrophosphoric acid is formed, the solution becoming acid; the alkaline pyrophosphate does not appear to undergo any change. Some metals can be equally readily separated by electrolysis from neutral or acid solutions of the double salts, with others the acidity of the solution resulting from the electrolysis prevents the proper deposition of the metal, but in almost all of these instances ammonia or ammonium carbonate (sesquicarbonate) can be added to the solution of the double salt without causing a precipitate to fall and thus the electrolysis can be effected in an alkaline solution. Sodium hydrate produces a precipitate in most cases. Since the solution can be kept alkaline during the electrolysis, chlorides, nitrates, and sulphates are equally applicable for the determinations. If the alkaline pyrophosphate be added to the metallic salt in quantity only sufficient to form the double pyrophosphate, but not to redissolve it, the precipitate can be dissolved in ammonia or in ammonium sesquicarbonate in all those cases in which these reagents can be added to a solution of the double salt in excess of alkaline pyrophosphate without producing a precipitate. The soluble double salts are not precipitated by the addition of ammonium oxalate. Dilute acids precipitate what appear to be acid pyrophosphates from solutions of these double salts; these precipitates dissolve in an excess of dilute mineral acid. Some of the solutions of the double pyrophosphates are precipitated on warming; for this reason it is preferable to have the solutions of the sodium pyrophosphate and of the ammonium carbonate ready made up. The solubility of sodium pyrophosphate is about 1:10 at 18°; ammonium pyrophosphate is more soluble (1:1, about), but there does not appear to be any advantage in using it and it is far more expensive. The above facts are taken advantage of for the quantitative determination

of metals by electrolysis of solutions of their double pyrophosphates. The following is an abstract of these methods as applied to the various metals. In all cases satisfactory analytical results are given. The only previous work on the electrolysis of these salts is by T. Moore (*vide Chem. News*, **53**, 209).

Nickel.—The double salt forms a white-green precipitate which dissolves in an excess of the alkaline pyrophosphate to form a yellow-green solution; this solution turns green on the addition of ammonium carbonate, and blue on the addition of ammonia. The solution of the double pyrophosphate or that containing ammonium carbonate is the best for the electrolysis. A current varying from 2—20 cc. of electrolytic gas per minute can be used. A current of 2—3 cc. precipitates 0.2—0.3 grm. of nickel in 24 hours. Heating hastens the separation. The nickel is deposited on the cathode as a grey-white film, but must be washed without breaking the current. The washing is conducted as usual; the complete precipitation of the nickel is tested for by ammonium sulphide.

Cobalt.—The double salt is pale red, the solution in excess of the precipitant violet; the colour is not changed by the addition of ammonia—ammonium carbonate turns it first brown and then violet. The electrolysis is effected as in the case of nickel; a current of 10—15 cc. is required towards the completion of the separation.

Iron.—Both ferric and ferrous salts behave normally; the precipitated double phosphates are white. The addition of ammonium carbonate (ammonia causes the separation of hydrate at the anode) is necessary. A current of 20—30 cc. is sufficient in most cases, but an increase is desirable towards the end of the precipitation to get the last traces down; the metal is iron-grey in colour and must be washed without breaking the current.

Manganese is separated as hydrated peroxide at the anode, and the separation is complete if the precipitated double phosphate is dissolved in ammonia and electrolysed with a current of 0.1 cc. for solutions containing less than 0.02 grm. of Mn per 100 cc. of solution and with a current of 0.01 cc. for solutions containing up to five times that amount. Even towards the end of the reaction the current must not exceed 0.4 cc. of electrolytic gas per minute.

Zinc.—The solution of the double pyrophosphate, to which ammonium carbonate is added, is electrolysed with a current of 5—10 cc., which should be increased to 15—20 cc. towards the end of the determination. The precipitate sticks well to the dish and can be removed by cold aqua regia without injury to the dish. An anode of platinum wire is preferable to one of platinum foil.

Cadmium.—A solution of the double pyrophosphate in a good excess of ammonia is electrolysed first for a few seconds with a current of 2—3 cc. in order to overcome the polarisation and then with a current of 0.3 to 1 cc. which should be increased to 5 cc. towards the close of the determination. The precipitated metal is silver-white and adheres well to the dish.

Copper.—The simple solution of the double pyrophosphate in excess of the alkaline pyrophosphate gives the best results with a current of 0.1 cc. which can be increased to 1 cc. towards the end of the determination. If the solution be acidified with nitric or with sulphuric acid the deposition can be effected in the usual way, since the presence of the free pyrophosphoric acid does not interfere at all.

Silver.—The double pyrophosphate of silver and sodium is treated with nitric acid or with potassium cyanide and electrolysed with a current of 0.01 to 0.20 cc. (*this Journal*, 1889, 257).

Mercury.—Mercurous salts must be first oxidised with nitric acid. The mercuric salt is converted into the double pyrophosphate, treated with ammonia and electrolysed with a current of 2 cc. which will precipitate 0.1 grm. of metal in 5—6 hours. The precipitated metal is washed as usual and then dried in an exsiccator over sulphuric acid for a short time.

Tin.—A very strong current is needed to separate tin from a solution of the double stannic pyrophosphate, but the separation is not quantitative. With stannous salts a portion of the salt separates at the anode in the stannic form which cannot be completely reduced to metal.

Chromium is oxidised to chromic acid. If the solution contain cobalt, nickel, or iron, the presence of the chromic acid interferes with their precipitation.

Lead.—The double pyrophosphate is soluble in excess and can be treated with ammonium carbonate without a precipitate separating. On electrolysis the solution the lead is partially separated at the cathode as metal and partly at the anode as peroxide. Ammonia precipitates the double pyrophosphate.

Thallium behaves like lead.

Bismuth.—The dilute slightly acid solution of the bismuth salt is treated with 4–5 times as much sodium pyrophosphate as is required for the formation of the double salt and made alkaline with ammonium sesquicarbonate; 3–5 grms. of ammonium oxalate are then added to the solution, and the electrolysis effected by a current of 0.1 to 1.0 cc., which is gradually increased to 2–3 cc. A current of 0.5 cc. will precipitate 0.25 gm. of bismuth in 12 hours; when more metal is present a weaker current must be used and 48 hours are necessary to precipitate 0.75 gm. of the metal. A coil of platinum wire is best for the anode. Towards the end of the decomposition traces of peroxide separate at the anode; these must be dissolved in oxalic acid, and it takes 4–5 hours to completely precipitate the redissolved portion. The complete precipitation is tested for by sulphuretted hydrogen. Owing to the readiness with which the metal oxidises it is advisable to dissolve it in nitric acid and convert it into the oxide by ignition, in which state it is weighed. The author finds that Moore's method (to treat the solution of the salt with tartaric acid, make it alkaline with ammonia and add a large excess of syrupy phosphoric acid, vide Chem. News, 53, 209) does not yield a very even deposit, and that the metal does not adhere well to the dish.

Antimony.—The precipitation from a solution of the double pyrophosphate treated with ammonium sesquicarbonate is not quantitative.

Separation of Metals.—Nickel, cadmium, zinc, and mercury may be separated from manganese by treating the solutions of their double pyrophosphates with 15 per cent. of ammonia (conc.) The manganese is first separated as peroxide by a weak current (v. ante) and the precipitation of the remaining metal completed in a second dish by a stronger current. Copper and manganese can be determined simultaneously, care being taken to use only a very weak current. Copper, cadmium, and mercury can be separated from manganese by acidifying the solution of the double pyrophosphates with sulphuric or nitric acid, and then separating the first-named metals.

In order to separate manganese from iron or from cobalt the solution of the double pyrophosphates (after being almost neutralised by ammonia, if acid) is electrolysed by a current of 15–20 cc. after the addition of 4–8 grms. of ammonium oxalate when the iron or cobalt is precipitated, the manganese remaining in solution. The method requires very careful working to give accurate results.

Cadmium is separated from zinc, iron, nickel and cobalt by electrolysis a sulphuric acid solution, when the cadmium alone is precipitated. To separate cadmium from manganese, sodium pyrophosphate must be first added to the solution, which is then acidified with sulphuric acid and electrolysed.

The double pyrophosphates of magnesium and uranium are precipitated by ammonia, not by ammonium sesquicarbonate; that of aluminium is not precipitated by ammonia. None of these are decomposed on electrolysis, and iron, nickel, cobalt, and zinc can thus be separated from them, but the presence of phosphoric acid in the resulting solution interferes with their subsequent determination.

—C. A. K.

Colour Reactions of Woody Cell Membranes. A. Ihl. Chem Zeit. 13, 831.

SCHIFF (Chem. Zeit. 9, 905) observed that urea and other nitrogenous compounds gave colour reactions on aldehydes. The author experimented with cinnamic aldehyde and obtained colour reactions with urea, commercial antipyrine, and an alkaloid.

Alcoholic solutions of urea and commercial antipyrine give with a mixture of concentrated hydrochloric acid and cinnamic aldehyde each a yellow colour turning reddish-yellow on boiling.

Woody matter which probably contains cinnamic aldehyde (this Journal, 1889, 640), moistened with an alcoholic solution of urea and concentrated hydrochloric acid, becomes of intense yellow colour. Human urine containing 2–3 per cent. of urea poured on wood and concentrated hydrochloric acid added, also produces the yellow stains after a short time.

Paper containing woody matter gives both of above reactions.

Commercial antipyrine in alcoholic or watery solution and concentrated hydrochloric acid poured warm on wood or paper containing woody matter produces an intense red stain, or if boiled with sawdust soon develops a red colour.

The author further notes that a dilute alcoholic solution of thymol with concentrated sulphuric acid very soon colours paper containing woody matter deep green.—D. A. S.

On the Relations between Chemical Composition and Absorption Spectra of Organic Compounds. Max Althausse and G. Krüss. Ber 22, 2065–2067.

It has been observed by exactly measuring the absorption spectra of organic compounds, that by addition of the methyl-, ethyl-, hydroxymethyl-carboxyl groups to a compound, a movement of the absorption bands from blue to red takes place; that this phenomenon is however reversed when a hydrogen atom is replaced by an amido-group or nitro-group. The author communicates some observations made on bodies of the Thionine group, which prove this hypothesis to be correct.—A. L.

On a Method of determining the Affinity Values of Organic Bases and Acids. E. Lelimmann. Ber. 22, 2101–2103.

The method is based on the fact that certain organic dye-stuffs change their colour when either treated with alkalis or acids. The quantity of the dyestuff can then be determined by a spectro-photometric apparatus. As a basic colouring matter, dimethylamidoazobenzene was used. Alcohol of 25 per cent. dissolves it to a yellow liquid, which allows all green rays to pass through. Little hydrochloric acid colours the solution intensely red, and it shows now in the green a large absorption band. The method is very simple. The hydrochloric acid salts of the bases to be examined are added to the yellow solution, and the change of colour is determined—if it be little, the base is comparatively strong, and *vice versa*. Aniline, β -naphthylamine, and α -naphthylamine were thus examined. Aniline proved the strongest base, β -naphthylamine followed, and α -naphthylamine showed the least basic properties of the three.

The affinities of acids are determined according to the same principle. If molecular quantities of phenol and the sodium salts of the three hydroxybenzoic acids be dissolved in equal quantities of water, and equal quantities of phenolphthalein be added to each solution, in the case of the salicylic acid a red colour is instantly produced by a drop of dilute caustic soda, whilst with phenol the first drops are without any effect, and then gradually a red tint is developed. From this it follows that the CO₂ONa group acts as weakening the effect of the OH in the ortho-position, as a little strengthening that of the OH in the meta-position, whilst that of the OH in the para-position is very sensibly strengthened. Further communications on this subject will follow.—A. L.

Colour Reaction of Cocaine Hydrochloride. M. Gockner.
Pharm. Zeit. **34**, 471.

This reaction is produced in the following way: a few crystals (0.1 grm.) of resorcinol are placed on a watch-glass and covered with 6–7 drops of pure concentrated sulphuric acid, and to this is added 0.02 grm. of cocaine hydrochloride. A violet reaction ensues and a beautiful cornflower blue is produced. A few drops of caustic soda solution turn the blue colour into bright red.—W. M.

On the Presence of Pectous Substances in Plants.

L. Mangin. Compt. Rend. **109**, 579–582.

A METHOD is described for detecting the presence of pectous substances in plants by a microscopic examination of their sections. It is based on the use of suitable staining reagents such as Bismarck brown, Methylene blue, &c., which do not stain cellulose, but stain pectous substances, nitrogenous matter, lignite, &c., in neutral or slightly acid solution. The colouration of the pectous substances is easily removable by treatment with alcohol, glycerol, &c., whilst that of the nitrogenous matter, &c. is permanent. The treatment with the above dyes may be followed by the application of such dyes as Induline, Nigrosine, &c., which do not colour cellulose or pectous substances, but stain nitrogenous matter, lignite, &c.—A. L. S.

Examination of Carbohc Acid and Cresolate Oil. W. W. Staveley. Chem. Zeit. **13**, 1126–1127.

THE author notes the following sources of error in various methods: Too little soda solution is apt to be used; for example, 1 grm. of NaHO is equal to 2.35 grms. of anhydrous phenol, or 2.7 grms. of anhydrous cresol, and to 3 grms. of tar acids or crude carbohc acid (taking the latter as largely composed of cresylic acid and higher homologues) with from 12 to 16 per cent. of water.

Thus, in the common method by agitation, a 10 per cent. soda solution should be used and four times (instead of only twice) the volume should be used, the alkaline solution acidified and shaken with benzene and read off.

This is preferable to reading after the agitation with alkali, as in that case any water is estimated as carbohc acid. Benzene is preferable, cresol being only soluble in petroleum containing 10 to 20 per cent. of coal-tar oil. Further distilled cresol containing 2–3 per cent. of naphtha dissolves to a clear liquid with twice its volume of 10 per cent. caustic soda solution.

The same errors occur in cases of carbohc powder testing. The author shows that unless the amount of caustic soda be increased the method of R. Williams (this Journal, 1889, 826) is inapplicable to powders containing over 20 per cent. of anhydrous cresol, or 22.5 per cent. anhydrous carbohc acid. Toth (this Journal, 1886, 618) appears to use too strong caustic potash solution as concentrated potassium, or sodium cresylate is soluble in excess of hydrocarbon oils. As to the method of Bach and also Muter and Konigsh (Analyst, **12**, 191) a better result is got by using saturated calcium chloride solution, but the author prefers agitating 50 cc. of the crude carbohc acid with 30 to 50 cc. of benzol and 30 cc. of 50 per cent. sulphuric acid. Although benzene is not absolutely necessary in case of refined or distilled acid, the author recommends its use.

With regard to Tidy's process, in which 20 cc. of NaHO (sp. gr. 1.2) are used. This solution would contain 4.23 grms. of NaHO, equivalent to 12.69 grms. of tar acids and thus becomes erroneous for larger amounts. Cases are known to the author where buyers have actually insisted on 20 per cent. of tar acids being shown to be present by Tidy's test. Tidy's method is also open to the objection that the solution of tar acids on neutralising is disregarded; 150 cc. contains at least, and often more than, 1 grm. of crude acids dissolved.

The author considers all results should be reported as anhydrous phenols.—D. A. S.

Determination of Value of Crude Cocaine. E. R. Squibb.
Pharm. Rundsch. **7**, 186.

Two grms. of an average sample of the crude cocaine is stirred with 12 cc. of ether (sp. gr. 0.725) in a tared beaker, filtered and washed with ether, and the undissolved portion determined by weighing the beaker and the dried filter with residue having a second dried filter paper as counterpoise. The ethereal solution is shaken in a separating funnel successively with 10 cc. of normal oxalic acid solution, with 10 cc. of water containing two drops of normal oxalic acid solution, and twice with about 3 cc. of water. The aqueous extracts are united and the separating funnel washed out with a mixture of 15 cc. of ether and 2 cc. of water; this is also added to the acid solution. The aqueous solution is again separated from the ether, and the latter after being twice extracted with 3 cc. of water (which is added to the cocaine oxalate solution) is mixed with the original ethereal extract. The whole of the ether is then evaporated down and the impurities of the crude cocaine soluble in ether determined. The separating funnel is washed out with a mixture of 15 cc. of ether and 2 cc. of water into the aqueous solution of cocaine oxalate contained in a second separating funnel. The whole is treated with 10 cc. and three drops of normal sodium carbonate solution in order to liberate the cocaine. The solutions are separated and the ether washed twice with 3 cc. of water; the ethereal solution is then poured into a tared beaker and the separating funnel washed out with a mixture of 10 cc. of ether and 3 cc. of water which is added to the oxalate solution. The latter is treated with one drop of normal sodium carbonate solution and well shaken; the ethereal solution is washed with a few drops of water and added to the rest of the ether. On evaporating off the ether, the cocaine separates in crystals which are dried at 90° and weighed. An analysis of crude cocaine gave:—Moisture, 3.25 per cent.; residue insoluble in ether, 5.25; soluble in ether, 0.50; pure alkaloid, 89.94; loss, 1.06 per cent. The amount of pure cocaine varies from 78 to 94 per cent.

—N. H. J. M.

Detection and Estimation of Sodium Bicarbonate in Milk.
L. Padé. Compt. Rend. **109**, 154–156.

ALTHOUGH a drop of decinormal acid is always sufficient to render acid the ash obtained by the ignition of 10 cc. of pure milk, the titration of the ash will not indicate the amount of carbonate which has been added, as during ignition it reacts on the calcium phosphate in the ash, according to the equation—

To determine the total amount of sodium bicarbonate added, the alkalinity of the soluble ash must be ascertained, and also the amount of sodium phosphate in it, as 284 parts of this corresponds to 336 of sodium bicarbonate. The phosphate is best estimated by titration with uranium solution, using cochineal as indicator.—E. E. B.

Beet Analysis. Journ. fabr. Sucre, **30**, 30–34.

IN connexion with Vivien's communication on an apparatus for the direct estimation of sugar, in which a process of aqueous extraction is carried on, Pellet says that he has also devised a similar arrangement, consisting of a tube and suitable cock by which he is enabled to completely extract the normal weight of beet juice prepared by the Pellet-Lomont rasp with 200 cc. of water. To ensure complete accuracy a second extraction is made, and both solutions are polarised, the first after the addition of 5–6 cc. of acetate of lead, the second requiring only a few drops, and the results are added. The test lasts only 12 minutes. Hot water or alcohol may also be used for the extraction.—W. M.

Beet Analyses. Zeits. f. Zuckerind. **39**, 580.

CLERC considers that the question as to whether the alcohol of polarisation should replace Pellet's aqueous extraction method or not is still undecided, while, according to Sackel, Pellet's method is only to be recommended to those who know there is no appreciable quantity of optically active non-saccharine matter present. He also considers that Pellet's fundamental assumptions are incorrect.—W. M.

Pellet's Process of Beet Analysis. Zeits. f. Zuckerind. **39**, 591.

LIPPMANN fully discusses Pellet's process and points out the numerous errors which Pellet has committed; he considers it very desirable that before being generally used the method be more completely tested. Sachs reports that Pellet's hot digestion process has given good results in Belgium, and also in his own hands, but that beets showing abnormal variations with the alcohol method were not examined; on the other hand he does not consider that the cold digestion process gives good results, and he points out that the so-called "Pellet warm digestion" originated with him, and the "cold digestion" with Van Niessen, who showed it to Pellet.—W. M.

Estimation of more than 10 Per Cent. Invert Sugar in Factory Products. Zeits. f. Zuckerind. **39**, 734.

HILLER has calculated a more complete table in extension of the figures obtained by Meissl and Herzfeld. The direct polarisation (P) of the normal weight of the sample is determined. The lead is precipitated in an aliquot portion of the filtrate by sulphate of soda, and the solution is made up to a known volume and filtered, and the invert sugar (I) estimation is carried out in 50 cc. of the filtrate, this corresponds to 200—300 mgrm. Cu.

The quantity of substance *p* contained in the 50 cc. has approximately $\frac{\text{Cu}}{2}$ grms. invert sugar; 100 grms. accordingly contain—

$$I = \frac{100 \text{ Cu}}{p} \frac{2}{2}$$

and since—

$$C \text{ (cane sugar)} + I = P + \frac{100 \text{ Cu}}{p} \frac{2}{2}$$

there is no—

$$P + \frac{100 \text{ Cu}}{p} \text{ total sugar,}$$

$$\frac{100 \text{ Cu}}{p} \text{ invert sugar,}$$

or on 100 total sugar—

$$\frac{100 \text{ Cu}}{2} \times 100 \\ p \cdot P + 100 \frac{\text{Cu}}{p} \text{ invert sugar present.}$$

Now, $C \approx 100 - I$ therefore $C : I$ is known.

Accordingly, the calculated factor *F* is taken from the following table and from the equation $I = \frac{\text{Cu}}{2} F$, the exact

percentage of invert sugar is calculated. The table is as follows:—

C : I.	I in Mgrms.						
	200	175	150	125	100	75	50
0 : 100	56.4	55.4	54.5	53.8	53.2	53.0	53.0
10 : 90	56.3	55.3	54.4	53.8	53.2	52.9	52.9
20 : 80	56.2	55.2	54.3	53.7	53.2	52.7	52.7
30 : 70	56.1	55.1	54.2	53.7	53.2	52.6	52.6
40 : 60	55.9	55.0	54.1	53.6	53.1	52.5	52.4
50 : 50	55.7	54.9	54.0	53.5	53.1	52.3	52.2
60 : 40	55.6	54.7	53.8	53.2	52.8	52.1	51.9
70 : 30	55.5	54.5	53.5	52.9	52.5	51.9	51.6
80 : 20	55.4	54.3	53.3	52.7	52.2	51.7	51.3
90 : 10	54.6	53.6	53.1	52.6	52.1	51.6	51.2
91 : 9	54.1	53.6	52.6	52.1	51.6	51.2	50.7
92 : 8	53.6	53.1	52.1	51.6	51.2	50.7	50.3
93 : 7	53.6	53.1	52.1	51.2	50.7	50.3	49.8
94 : 6	53.1	52.6	51.6	50.7	50.3	49.8	48.9

Estimation of Invert Sugar Dents. Zuckerind. **14**, 1098.

ACCORDING to Scheller a Soldaini solution of constant composition is easily prepared by dissolving 15.8 grms. of pure copper sulphate and 7.2 grms. of potash, each in 100 cc., mixing them, and pouring the whole, along with the precipitated hydroxide, into 1,700 cc. of a solution of 594 grms. of acid potassium carbonate in water. The mixture is heated for one hour on the water-bath, allowed to cool, and then made up to 2,000 cc. 1 cc. of this reagent contains 2 mgrms. of Cu. The same quantity of copper sulphate may also be added directly to the hot solution of acid potassium carbonate, and then after heating for 15 minutes the solution is allowed to cool and made up to 2,000 cc. This reagent is of constant composition, no precipitation having taken place within three months.—W. M.

Soldaini's Reagent of Constant Composition. Zeits. f. Zuckerind. **39**, 773.

ACCORDING to Striegler it is necessary to have certain fixed proportions between the components in order to have a stable solution, and especially no more bicarbonate of potassium must be used than will afterwards remain in solution at the ordinary temperature. To prepare 2 litres of the reagent, 12.77 grms. of copper sulphate are dissolved in cold water, soda is added to alkaline reaction, the precipitate is thoroughly washed with about $\frac{2}{3}$ litre of water, and then heated in a flask containing about 2 litres of water and 597.7 grms. potassium bicarbonate, on a water-bath to 40°–50° C. until the bicarbonate has dissolved, then over a naked flame to 66° until the hydroxide is completely dissolved, and finally the solution is boiled vigorously for 1–1½ hours until the excess of bicarbonate is decomposed. After cooling, the solution is made up to 2 litres and filtered, and is then quite stable, not decomposing even after half an hour's boiling. If the solution be diluted with 5 volumes

of water, greenish-blue hydroxide is precipitated which is converted into the black oxide on heating.

The solution prepared according to Soldani's original receipt and diluted with 20 vols. of water behaves in the same way, containing perhaps the copper in the form of hydroxide instead of carbonate.

This decomposition explains the irregularity of the results frequently obtained with Soldani's solution. For analysis 150 cc. of the reagent is boiled vigorously and 50 cc. of invert sugar solution is added and the solution is again boiled for five minutes. In this way the following results were obtained:—

50 cc. containing 50 mgrms. of invert sugar (I) gave 142 mgrms. of Cu, 50 mgrms. I + 5 grms. of cane sugar (C), 142.2 mgrms. Cu, 25 mgrms. of I + 5 grms. C, 71.8 mgrms. Cu, 12.5 mgrms. I + 5 grms. C, 37 mgrms. Cu, 5 mgrms. I + 5 grms. C, 17.5 mgrms. Cu, 2 mgrms. I + 5 grms. C, 7.2 mgrms. Cu. The statement of Bodenbender and Scheller that the amount of copper is proportional to the invert sugar is not quite correct, at least for small quantities of sugar.

From special experiments it was found that in the presence of 5 grms. of cane sugar the proportion of the copper to the invert sugar was as follows:—

Found, mgrms. of Cu	53,	45,	40,	35,	30,	25,	20,	15,	10,	5
Sought, mgrms. of	100,	16.3,	13.7,	11.5,	9.4,	7.5,	5.8,	3.5,	2.6,	1.1.
invert sugar ...										

—W. M.

On the Estimation of Tannin with Potassium Permanganate. F. Gantter. Zeits. f. angew. Chem. 1889, 577—580.

LÖWENTHAL'S method for estimating tannin, as improved by von Schröder, has come into very general use, and the commission for determining a uniform method of tannin estimation has accepted it, and it is known as the "cubic-centimetre" method. This method has the advantage over most others of giving fairly uniform results, and such as agree well amongst themselves, providing the method of procedure is rigorously adhered to. A slight deviation, however, from the method of procedure causes irregularities, and many chemists have therefore become prejudiced against the method. The author has therefore tried to improve the method so that uniformly accurate results might be obtainable without difficulty.

He has attempted, and as the result shows successfully, to completely oxidise the tannin with permanganate, without the presence of a special indicator, by carrying out the oxidation in a hot instead of a cold tannin solution.

As a result of his investigations, he recommends the new method of procedure given below, which he has more especially applied to the estimation of tannin in oak-bark.

The solutions necessary are:—

(a.) Potassium permanganate solution, 1,000cc. containing 3.988 grms. i.e., 1 cc. = 0.001 gm. of tannin.

(b.) Oxalic acid, 1,000 cc. = 7.951 grms. crystallised oxalic acid.

(c.) Extract of oak-bark prepared in the usual way from 10 grms. of bark = 1000 cc. of solution.

(a.) and (b.) solutions may be looked upon as equivalent, cubic centimetre for cubic centimetre, to a pure tannin solution containing 1 gm. of dry pure tannin per litre.

The permanganate solution is standardised against the oxalic acid solution.

The method of procedure is as follows:—

Ten cc. of dilute sulphuric acid are added to 10 cc. of oak-bark solution, and then nearly heated to boiling; about 1 cc. of permanganate is then added. The red colour disappears. The gradual addition of permanganate is continued until the red colour begins to disappear slowly; as soon as this is the case the solution is again heated to boiling, and the permanganate solution is now only added drop by drop. The solution must be allowed to get perfectly limpid before the addition of the next drop. Towards the end of the reaction a small quantity of a brown precipitate (manganese hydrate) is formed, which, however, always again disappears on boiling vigorously so long as the reaction is

not complete. As soon as the precipitate no longer disappears, even on vigorous boiling, about 1cc. of permanganate solution is allowed to run in in excess; the mixture is then subjected to vigorous boiling. A thick brown precipitate separates out. Oxalic acid (from a second burette) is now run into the hot solution, until the latter is perfectly limpid, and the titration is then finished off with permanganate. After deducting the number of cubic centimetres of oxalic acid solution from the number of cubic centimetres of permanganate solution used, the difference in cc. gives us the percentage of tannin directly.

It is of course necessary to carry out a second titration with a portion of the extract which has been precipitated with skin (a gelatin solution may do as well, see Sutton, Volumetric Analysis, 278) and the amount of permanganate solution used in this second titration must be deducted from the first. As a rule, however, the quantity to be deducted is so small that for technical purposes it may be neglected.

Experiments on the estimation of tannin in oak bark show that the results obtained by this method are identical with those obtained by the gravimetric method, but that the quantity of tannin found by the Löwenthal-Schröder method is about one-half of that found by the new and gravimetric methods.

The new method can also be used in determining the value of other tanning materials, since the oxidation of the tannin from various sources always requires an amount of permanganate differing only slightly from that required for pure tannin. The author is still engaged with the determination of the actual quantities of permanganate necessary in these cases.—F. W. T. K.

New Books.

FEUERUNGSANLAGEN. Für Häusliche und Gewerbliche Zwecke, von DR. FERD. FISCHER, Zugleich als 4^{te} Auflage von "Meuzel's Bau der Feuerungsanlagen" mit 299 Abbildungen. Karlsruhe: J. Bielefeld's Verlag. 1889. London: H. Grevel and Co., 33, King Street, Covent Garden.

This important work is mainly a collection of the writings of Dr. Fischer on the general subject, now arranged, with certain additions, in book form. The text covers 206 pages of an 8vo. volume, well illustrated with 299 wood engravings. The price of the book is 8s. 6d. unbound, elegantly bound 10s. The subdivision of the general subjects is effected as follows:—1. Fuels. 2. Investigations in the Application of Fuels. 3. Theory of Combustion; Smoke. 4. Grates and Stoking Arrangements. 5. Chimneys. 6. Heating and Ventilation. 7. Boiler Arrangements. 8. Blind Furnaces. 9. Boiler Furnaces. 10. Generator Gas. 11. Illuminating and Water-gas. 12. Glass Furnaces. 13. Furnaces for Porcelain and Earthenware. 14. Furnaces for Lime and Cements. 15. Furnaces for Breweries and Spirit Distilleries. 16. Other Furnace Arrangements.

DIE SYNTHETISCHEN DARSTELLUNGSMETHODEN DER KOHLENSTOFF-VERBINDUNGEN. Von KARL ELBS, Erster Band. Leipzig: Johann Ambros Barth. 1889. London: H. Grevel and Co., 33, King Street, Covent Garden.

This is an attempt to collect together all the known synthetical methods of preparation of the carbon compounds. This collection was to be completed in two volumes, of which the present is the first. It is a work of 8vo. size, containing 284 pages of subject-matter, and an alphabetical index. The price is 7s. 6d.

Chap. I. deals with syntheses by means of metallo-organic compounds. II. Syntheses of Cyanogen Compounds. III. Syntheses of Molecular Re-arrangements. IV. Syntheses

by Addition: (a) By Addition of the Anhydrides of Acids. (b) By Addition of Carbon Monoxide. (c) Synthetic Addition Processes with Aldehydes and Ketones. (d) Syntheses by Addition of Hydrogen to Aldehydes and Ketones. (e) Polymerisation of Unsaturated Hydrocarbons and their Derivatives. (f) Polymerisation of Nitrils.

HANDBOOK FOR GAS ENGINEERS AND MANAGERS. By THOMAS NEWBIGGING, Member of the Institution of Civil Engineers. Fifth Edition, Enlarged. London: Walter King, Office of the "Journal of Gas Lighting," &c., 11, Bolt Court, Fleet Street, E.C. 1889. Price, bound in cloth, 15s.; morocco, gilt, 18s.

OCTAVO volume, splendidly bound in morocco and gilt, containing Preface, Table of Contents and of Illustrations, and 524 pages of Subject-matter. All the requirements, statistics and data needed by the gas engineer are here supplied, and supplied as concisely as possible. The text is very fully illustrated with 193 engravings and tables of various data and statistics. The following is an abstract of the subjects treated of:—Coal and Cannel. The Storage of Coal. Spontaneous Ignition of Coal, &c. Testing Coal for its Producing Properties. Retort-house Benches, Retorts and Mountings. The Slaking of Hot Coke. Fuel for Carbonising. Generator Furnaces and Regeneration. The Dinsmore System of Gas Making. Charging and Drawing Retorts by Machinery. Naphthalene. Exhausters. Scrubbers. Bye-pass Mains and Valves. The Tar Well. Purification and Purifiers. Gas Holders. Main Pipes and Distribution. Service Pipes and Fittings. Consumers' Gas Meters. Testing Meters. Public Illuminations. Coloured Fires. Various Standards of Light. Relative Value of different Illuminating Agents. The Gas Industry of the United Kingdom. Coefficients of the Cost, &c. of the Buildings, Apparatus, Machinery, and Plant of a Gas Works. Alphabetical Index.

DIE CHEMIE DES STEINKOEHLENTHEERS MIT BESONDERER BERÜCKSICHTIGUNG DER KÜNSTLICHEN ORGANISCHEN FARBSTOFFE. Von GUSTAV SCHULTZ. Zweite vollständig umgearbeitete Auflage. Zweiter Band. Die Farbstoffe. Fünfte Lieferung. 1889. Brannschweig: Friedrich Vieweg und Sohn. London: H. Grevel & Co., 33, King Street, Covent Garden.

THE fourth part of the Second Volume closed with an unfinished report on the Safranines; the fifth part contained in the volume now referred to takes up and continues the subject on page 769, and it is concluded on page 802. CHAP. XL then commences with the Indulines and Nigrosins, and is completed on page 835, when the subjects Aniline black and Naphthylamine violet are considered in CHAP. XLI. The Quinoline colours are described in CHAP. XLII, viz., Flavaniline, Flavaniline S, Cyanine, Acridine colours, Phosphin, and Benzoflavin. In CHAP. XLIII the Indigo Group is the subject of study, and under this head Natural and Artificial Indigo and Indigo blue and its Derivatives are treated of. CHAP. XLIV, on the Diehroins and Allied Colouring Matters, and Colours of Unknown Constitution, extends to the final page of the volume, which, however, does not seem to be the concluding volume of the entire work. The entire text thus extends from page 769 to page 960. There are several illustrations in the form of wood engravings.

AN INTRODUCTION TO CHEMICAL SCIENCE. By R. P. WILLIAMS, A.M., Instructor in Chemistry, English High School, Boston, U.S.A. Edited and Revised by B. P. Lascelles, M.A., F.C.S., Assistant Master and Librarian, Harrow School. London and Boston, U.S.A.: Guise & Co. 1889. Price 3s. 6d.

As stated in the Editor's preface "this manual is purely introductory, and it aims only at giving an outline of the science which must be filled up in greater detail from larger works."

It is hoped that this volume will fill the gap indicated in the *Report on Chemical Teaching*, issued by a committee of the British Association in 1888, as existing between the Natural Philosophy Primer and the minute and detailed text-book.

The work takes the form of a crown 8vo. volume, is bound in cloth, and contain 209 pages of subject-matter, an Appendix covering 5 pages, and an alphabetical index. The text is embellished with 50 wood engravings.

In this little work the attempt has been made to introduce into the text (usually devoted to pure chemistry) also those elements of chemical physics which have become more and more closely allied to pure chemistry, such as Electrolysis, Electro-chemical relation of the Elements, and Photography.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete des technischen und industriellen Chemie mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 1888. *Zeites Halbjahr. Zweite Hälfte.* Berlin: R. Gertner's Verlagsbuchhandlung, Hermann Heyfelder. S.W. Schönebergerstrasse, 26. London: H. Grevel and Co., 33, King Street, Covent Garden.

OCTAVO volume in paper cover; the second issue for the second half-year of 1888. It contains 178 pages of subject-matter, copiously illustrated with wood engravings. In the text the following subjects are treated of:—Food-stuffs and Confections; Paper; Photography; By-products of various kinds; Residual Matters; Manures; Disinfection and Sanitation; Soap; Explosives, &c. Preparation and Purification of Chemicals. Chemical Analysis. Apparatus, Machinery. Electro technology. Technology of Heat. Appendix: Adulterations of Trade Products, &c. New Books. Alphabetical Index.

DER PRAKTIISCHE KLEIDERFÄRBER NACH DEN ANFORDERUNGEN DER GEGENWART. Von CARL SCHULZ. Nebst einem Anhang über Kleider-Appretur. Vierte der Neuzeit entsprechend vollständig umgearbeitete Auflage. Leipzig: Verlag von Gustav Weigel. London: H. Grevel and Co., 33, King Street, Covent Garden.

SMALL 8vo. volume, in paper cover, can be had with pattern card at a price of 9s., without pattern card 3s. It contains 101 pages of text, entirely confined to the operations and requirements of the dyer and finisher. CHAP. I.—Silk Dyeing. CHAP. II.—Dyeing of Half Silks, Silk and Cotton, &c. CHAP. III.—Dyeing Woollens. CHAP. IV.—Dyeing of Half Woollens. CHAP. V.—Dyeing of Cotton Goods. CHAP. VI.—Finishing of Silk, Woollen, Half-Woollen, and Cotton Goods.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

SWEDEN.

Modifications in Customs Tariff.

The *Bollettino di Legislazione e Statistica Doganale e Commerciale* for October says that the Swedish Diet has approved, in its 1889 session, the following modifications in the Customs tariff:—

Note.—Krone = 1s. 1½d. Kilog. = 2·204 lb. avoirdupois.

No. in Tariff.	Classification of Articles.	Rates of Duty.
112	Varnishes : Spirit.....	Kron. Oro Kilog. 1·20
	Other.....	" 0·30
	<i>Note.</i> —Spirit varnishes imported in receptacles containing more than 20 kilogs., and of which the alcohol may be denaturalised in the prescribed manner, are subject to the duty of.....	" 0·40
141	Colours prepared in oil.....	" 0·15
289	Collodion.....	Litre 1·75
669	Vinegar and acetic acid : In casks containing up to 1 per cent. of acid.....	" 0·10
	Of greater acetic strength, for each degree above.....	" 0·01
679	In other receptacles, not taking account of the acetic strength.....	" 1·00

—Board of Trade Journal.

AUSTRIA-HUNGARY.

Customs Treatment of Alizarin.

The *Moniteur Belge* for the 7th November last says that an order has been issued by the Austro-Hungarian Customs authorities providing as follows:—

The alizarin subjected to the conventional rate of 1·50 florins only includes the four following categories: pure alizarin, anthra- or isopurpurin, flavopurpurin, and purpurin.

Other colours of alizarin (the derivatives of alizarin, such as orange, blue, green, yellow, alizarin, &c.) fall under the application of Article 330 of the tariff, and pay 10 florins per 100 kilog. as dyeing materials extracted from tar.

Customs Classification of "Ammonine."

According to the *Moniteur Belge* for the 27th October, the Austrian Customs authorities have decided that ammonine (substance made from soda and sulphide of ammonium) must be classified in Category 312a, and pay duty at the rate of 80 kreutzers per 100 kilogs.—*Ibid.*

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Franc = 9⁴/₁₀d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities during the month of October last:—

Salicylate of soda.—Category 17. Duty, 1 franc per quintal.

Cassel-brown.—Category 30. Duty, 60 cents. per quintal. Lead-yellow (*Bleigelb, Deckgelb*).—Category 35. Duty, 3 francs per quintal.—*Ibid.*

UNITED STATES.

Recent Customs Decisions.

The following decisions affecting the classification of articles in the Customs tariff, and the application of the Customs law of the United States, have recently been given by the United States Customs authorities:—

Soap in cakes, wrapped in tinfoil, with an outside covering of paper, each cake stamped "Calvert's carbolic toilet soap," is dutiable under the provision in T. L., 8, for "soaps not otherwise provided for."

Calvert's purest carbolic medical soap is dutiable as toilet soap.

An article called toluidine is exempt from duty under provision in the free list (T. L., 559) for "aniline, crude."

Toluidine sulpho-acid is dutiable as a coal-tar colour.

Paper for use in making "ferro-prussiate paper" is dutiable as paper not otherwise provided for.

The fine copper contained in nickel matte is dutiable at the rate of 3½ cents per pound, under the provision in T. L., 186, for regulus of copper, in addition to the duty of 15 cents per pound on the nickel contained therein imposed by T. L., 191.

An impure grease, saponified by lime, which is not suitable for use as soap-stock, but which can be used as a lubricator for heavy iron bearings, such as car-axles, &c., is dutiable at the rate of 10 per cent. *ad valorem*.

Pure guaiac resin, the purity having been produced by refining, and commercially known as gum guaiac, is dutiable at the rate of 25 per cent. *ad valorem*.

Lemon juice, containing over 2½ per cent. of alcohol, is removed from the category of lemon juice, as specified in the free list, and is liable to duty at rates prescribed for alcoholic compounds in Schedule A. (T. L., 103), at 2 dols. per gallon for the alcohol contained therein and 25 per cent. *ad valorem*.

Certain so-called "saffron extracts" which do not exhibit the distinguishing characteristics of "saffron extract" and is positively a colour derived from coal-tar, are dutiable at 35 per cent. *ad valorem* under T. L., 82.—*Ibid.*

CUSTOMS TARIFF OF NICARAGUA.

The following is a statement of the rates of import duty now levied under the Customs tariff of Nicaragua. The duty in each case is leviable per Spanish *libra* or pound (100 English pounds avoirdupois are equal to 101·6 Spanish pounds).

Note.—Peso = 4s. 2d. (nominal value).

Articles.	Rates of Duty per Spanish Pound.
MEDICINES, DRUGS, &c.	
Oils, olive linseed, almond, castor, cocoa-nut, cod-liver, and any other similar oil.....	0·03

Medicinal sweetmeats or pastilles	0'15
Medicinal barks	0'15
Chalk, clay, Tripoli	0'02
Perfumed and medicinal essences	1'00
Sponges of any kind	1'00
Liquid amber	0'05
Gum arabic or gum lac	0'10
Glycerin	0'03
Lint	0'15
Senna leaves and rosemary	0'03
Soaps and syrups, medicinal	0'15
Linseed or linseed flour	0'03
Cocoa butter	0'15
Fat for ointments or pomades	0'05
Medicines in gelatin capsules, patented medicines, as well as balms and mixtures of oils in drugs, pastes, powders, in a liquid state, tragacanth, and medicines in any form and prepared in any way not specially mentioned	0'15
Medicines and drugs, in pastes, powders, liquids, tragacanth in any form, and prepared in any way, not specially mentioned	0'15
Mustard in seed or flour	0'03
Gall nuts	0'05
Oxide of zinc	0'04
Filtering paper	0'05
Pitch, resinous	0'02
Epsom and Glauber salts	0'02
Saltpetre or nitrate of potash	0'03
Sal-ammoniac	0'05
Caustic soda	0'02
Medicinal berries	0'15
Sulphate of iron	0'01
Sulphate of zinc or white vitriol	0'02
Sulphate of copper or blue vitriol	0'03
Sulphate of quinine	1'00
Persian sherbet	0'05
Turpentine	0'05
Utensils for chemists and druggists, of faience, stone, and composition, such as mortars, basins, &c.	0'03
Poisons for tanning, insects, &c.	0'10
Medicinal wines, such as quinine, extract of meat, &c.	0'15
Vaseline, easmoline, and petrolate	0'10
Bristol sarsaparilla, and other similar kinds	0'03
MISCELLANEOUS ARTICLES.	
Mineral oils such as camphine, petroleum, and naphtha	0'01
Perfumed oils	0'10
Alcohol	Prohibited.*

Articles.	Rates of Duty per Spanish Pound.
MISCELLANEOUS ARTICLES, &c.—<i>cont.</i>	
Tar, pitch, blacking	0'02
Starch or fecula of potatoes for industrial use	0'03
Manufactures of amber	0'50
Aniline and carmine	0'25
Electrical apparatus for telegraphs and telephones	Prohibited,
Varnish of any kind	0'03
Caoutchouc tissue, manufactured as shoes, capes, covers, boots, and other similar articles	0'25
Caoutchouc manufactured in articles of any kind not otherwise specified	0'30
White wax, pure or mixed, not manufactured	0'12
Articles of wax not specially mentioned	0'25
Beer	0'02
Glues of any kind	0'06
Colours and sizings of any kind not specially mentioned, in powders, pastes, or oil	0'04
Articles of celluloid of any kind	0'40
Dynamite	Prohibited,
Matches of all kinds	0'04
Fireworks of any kind	0'13
Perfumes of all kinds	0'13
Soap, common	0'02
„ superior, toilet soap, perfumed	0'10
Ochre and other coloured earths	0'40
Powder, blasting, under special authority of the Government	0'50
Powder, other	Prohibited,
Candles, tallow, wax, &c.	0'05

The following articles pay specific duties as under:—

Articles.	Rates of Duty.
Foreign spirits more than 12 degrees up to 25 degrees, inclusive by the Cartier alcoholmeter....	Pes. Cts. Bottle 0'40
Dos. more than 25 degrees by the Cartier alcoholmeter (with special authority of the Government) pay same duty as the preceding articles with an increase per degree in excess of	0'03

The following articles are free from import duty:—

Manure for agricultural use.
Still, under special authority from the Government.
Mercury for mines.
Lime and cement.
Coal and animal charcoal.
Crucibles for melting metals.

Articles not mentioned in the tariff pay the duties leviable on similar articles; those not mentioned in the composition of which there are several materials pay the duty leviable on the chief material; finally, for those not mentioned which cannot be classified there is levied 50 per cent. on the invoice value. If the original invoice is missing, a valuation of the goods will be made by experts.

The import duties are fixed on the gross weight without any deduction for cases and packages.—*Ibid.*

* Except under special permit of the Government. See below.

THE PREPARATION OF RAMIE FIBRE.

Ibid., pp. 705-711.

THE WORKING OF THE STATE ALCOHOL MONOPOLY IN SWITZERLAND.

Ibid., pp. 717-718.

EXTENSION OF THE ALCOHOL DRAWBACK IN GERMANY.

An order has just been issued by which German soap-makers are allowed to use alcohol in their manufactures free of duty, provided they conform to certain regulations. These rules are very simple, and consist simply in the manufacturer giving notice on an official form of the quantity of spirit which he intends to use, and the time when the manufacturing process is to take place. The alcohol is then forwarded to the works in bond, and in officially sealed packages, and at the appointed hour an Excise officer attends at the works, breaks the seal, and watches the incorporation of the alcohol into the soap-stock until the spirit has been fully mixed with the caustic-soda lye. The concession has been made specially in the interests of the manufacturers of transparent toilet soaps. For the manufacture of perfumery with duty-free alcohol facilities are already given.—*Chemist and Druggist*.

MISCELLANEOUS TRADE NOTICES.

ENGLISH MANURES IN THE DISTRICT OF LA ROCHELLE.

In the matter of artificial manures, the English have nearly lost the market, not from the bad quality of the manures supplied, but because they have not seen fit to sell their manures with guarantees of fixed price and strength.

The French laws against the adulteration of manures are particularly stringent.* They require that particulars shall be given of the origin, whether natural or manufactured, of the manures sold, with a detailed statement of their fertilising value, expressed by the quantity of nitrogen, potash, phosphoric acid, and other elements contained in them. The price is to be based upon the quantities of the respective constituents. English manure makers have not supplied manures in exactly the form required by the French farmers. They have been consequently manipulated by retailers, and "the English article, however good it may have been when it arrived, has often reached the farmers in an adulterated condition, and has got a bad name consequently."

Owing to the failure of English makers of manures to give satisfaction, for the reasons stated, and also because the manures are a little dearer than the French, some large manufactories have been established lately in France, but it is agreed that no better manures can be made than the English, and a good business could be done if English firms were willing to meet the requirements of the farmers and keep to the letter of the laws.—*Board of Trade Journal*.

PERFUMERY MANUFACTURE IN AUSTRIA.

The Vienna Chamber of Commerce reports that, in spite of many adverse circumstances, the Vienna perfumery industry is steadily expanding. The wealthier classes in Austria, who formerly would only use French or English

soaps and perfumery, are learning to appreciate the excellence of native manufactures, and since last year an export business, mostly with the East Indies, has grown up in certain goods, especially toilet soaps of medium qualities. Viennese glycerin soaps have been enabled to compete with English, French, and German made articles lately because drawback on the denaturalised spirit used in their manufacture is now granted to the Austrian makers, but hitherto perfumers have not been able to obtain an extension of the drawback regulations to alcoholic extracts and other perfumes. The German makers, on the other hand, enjoy complete immunity from any alcohol duty on goods exported, and are consequently able to take much of the East Indian trade which, but for these advantages, the Austrian makers would monopolise.—*Chemist and Druggist*.

THE PAPER INDUSTRY IN SPAIN.

The industrial movement at Bilbao continues unchecked, and among the many schemes in view, it is now reported that a paper mill, of the largest and most perfect style, will be established in a very short time. The paper industry in the country is mostly confined to the north of Spain, in the Basque provinces and in Catalonia; but there is still room for the importation of about 5,000 tons annually, particularly from Belgium. Although Madrid is a very large market for paper, the paper industry is not either extensive or prosperous, and is far from being in proportion to the wants.—*Industries*.

THE AUSTRIAN SUGAR TRADE.

This year's manufacture of raw beet sugar was over in Austria and Hungary by December 1st. There were, altogether, 215 factories, as against 210 last season, and an output of 60 million metrical centners, compared with 47 millions. The increase has been due partially to the greater area, but chiefly to the improved quality, and therefore larger yield, of this year's beetroot crop. The area showed an increase of 90 per cent., and the yield one of 29 per cent. The manufacture of raw sugar rose from 5½ million metrical centners to over seven millions, and, as the home consumption promises to remain stationary, Austria-Hungary will be able to export nearly twice as much as last year. Most of the raw and refined sugar available for export has already been sent to Germany, in order to use the Elbe route before the winter interrupts navigation.

The large profits made during the present season form an added inducement to extend the acreage devoted to beet, especially in Hungary, where the sugar industry has been taken up energetically by the first-class firms. About 20 new factories, some of unusual capacity, will be ready at the beginning of next season to compete with the Bohemian factories, not only for the home market, but also for the export trade, for which the Hungarians prefer the sea route *via* Fiume.—*Standard*.

BUTTERINE LEGISLATION IN HOLLAND.

The new Margarine Act passed by the Dutch Legislature last session will come into operation on 1st January next. In the main it follows closely the English Margarine Act, 1887; in fact this measure led to it. But the Dutch Act offers some important modifications. It will be criminal to use the word "butterine" for margarine mixtures, and all such compounds must be labelled "margarine" before they can be "delivered" or sold in the kingdom. But on the other hand, dairy butter, if not absolutely pure, can only be sold under the name of "butter substitute." Meanwhile a new compound will be manufactured shortly at Amsterdam, where a large factory is in course of erection for the purpose. That compound is a preparation from cocoa-nuts and similar oily products of the tropics. It is styled "cocoa-nut butter," and is stated to be an excellent substitute for butter in cooking, especially as it can be manufactured at a price much lower than either butter or margarine. In Amsterdam the new factory is started by the "Dutch Vegetable Butter Company."—*Industries*.

* See this Journal, Feb. 1888, p. 143.

THE PETROLEUM SUPPLY OF THE CAUCASUS.

The price of the raw material (naphtha) during the last two years has gone up from $1\frac{1}{2}$ copecks per pood of 36 lb. to 7 copecks, the present price, and there is no denying that formerly the supply was beyond the demand, and that now the reverse is the case; but this can easily be explained without coming to the conclusion that the supply is exhausted. Bearing in mind that the Trans-Caucasian Railway can only carry a fixed quantity of the refined kerosene to Batoum, on the Black Sea, for exportation, owing to the difficulties caused by the steep gradients, by far the greater part has to find an outlet to the Russian and European markets by the steamers and sailing vessels on the Caspian Sea, which carry the kerosene in bulk to Astrakhan at the mouth of the River Volga. Two years ago there was not sufficient carrying-power on the Caspian, so that freights went up enormously, with the result that so many ordered new steamers and sailing vessels that the supply is now excessive. In one year 15 new steamers were added; taking each as carrying 1,000 tons, you get 15,000 tons a trip, and, seeing each boat makes on an average 35 trips during the season, these alone added 525,000 tons to the carrying-power, exclusive of sailing vessels. Refineries were consequently extended to such an extent that the supply of the raw material is now insufficient, although the amount raised is no less than formerly.

It must be understood that the naphtha has, up till lately, only been bored for in one place, some nine miles from here, called Balakhani, which is only about $1\frac{1}{2}$ miles long by one mile broad in extent. Lately, a new place nearer town has attracted attention, and promises to eclipse Balakhani; it is called Bailoff Mees. There are many places in the vicinity where naphtha is known to exist, but as a bore-hole costs from 5,000*l.* to 6,000*l.*, people do not care to risk their money in experiments unless some one has already done so successfully close by. Bailoff Mees would have remained untouched if it had not been for the boldness of a Persian named Tagieff, who started boring there and found naphtha; he is now one of the wealthiest men here.

The conclusion, therefore, is not that the supply is becoming exhausted, but that through the facilities of export having so suddenly increased, the present supply of the raw material is insufficient to meet the demand, which supply only requires working to bring it up to the quantity required, and this is slowly being done.—*Ironmonger.*

COCOA-NUT BUTTER IN GERMANY.

The following is an extract from the last report of the United States Consul at Mannheim on the subject of the manufacture of cocoa-nut butter in Germany:—

"German chemists discovered in the cocoa-nut a fatty substitute for butter. This discovery was made by a Dr. Schlunk, practical chemist at Ludwigshafen-on-the-Rhine. Shortly after the discovery was made a firm was established in this city under the name 'P. Müller and Söhne,' which sunk a large amount of capital in an enterprise having for its object the production of the new article, to which they gave the name of 'cocoa-nut butter.' The results achieved have more than justified their expectations. The firm is not able to meet the constant demands made upon it. Although in existence only one year, it employs 25 workmen, who get from 25 to 75 cents. a day, has a 40-horse-power engine, and produces daily 3,000 kilos. of butter, which retails at from 55 to 65 pfennigs, or from 13 to 15½ cents. per pound, or 25 to 30 cents. per kilogramme.

"The nuts are obtained from almost all lands lying in the tropics, especially from the South Sea and Coral Islands, Arabia, the coast countries of Africa, and South America. Natives in countries where the nuts grow have for a long time used the milk of these nuts instead of food oils. It contains 60 to 70 per cent. of fat, and 23 to 25 per cent. of organic substances, of which 9 to 10 per cent. is of albumen. Liebig and Fresenius had already discovered the value of the cocoa-nut oil, or fat, but did not succeed in its production

as a substitute for butter. The new butter is of a clear, whitish colour, melts at from 26° to 28° C., and contains 0·0008 per cent. water, 0·066 per cent. mineral stuffs, and 99·9932 per cent. fat.

"It hardens at 19° C. It is better adapted, however, for the kitchen than for the dining-room, that is, for cooking purposes, than for the uses to which butter is put on our tables. It is neither disagreeable to the taste nor smell. In a country where real butter runs all the way from 25 to 35 cents. per pound, and cocoa-nut butter costs but 15 cents., a great future must open up before the latter. At present it is chiefly used in hospitals and other State institutions, but is also rapidly finding its way into houses or homes where people are too poor to buy butter. The working classes are rapidly taking to it instead of the oleomargarines, against which so much had been said in the papers during the last two or three years.

"The new butter is said to be singularly free from acids and other disturbing elements so often found in butter, especially that made from milk taken from cows diseased with tuberculosis. Here it is estimated that fully 10 per cent. of the milk-giving cows are so troubled. This absence of acids and other matter renders its digestion much easier, hence the preference already shown for the new article by hospitals and such institutions. There are those who do not hesitate to declare this new substitute as healthier, and infinitely preferable to the too often bad butter brought on the markets, and not to be named in the same breath with oleomargarines made too often from the diseased fat of horse and sheep flesh.

"When it is remembered that Germany has already some 50 factories making oleomargarines and other artificial butters, and that some 180,000 centners are produced annually, it will be readily seen that regular butter will have hard work to hold its own in a hundred uses against its new rivals, and especially so since the oleomargarines and artificial butters of all kinds are placed under severe, careful, and watchful State inspectors. It is hoped, however, that no losses, but gains rather, will arise; for besides the profits resulting from the new substitutes more meat and milk, as such will come on the markets, and consequently into use. If, with König, we assume that the principal nutriment—albumen, fats, and carbon hydrates are paid for in the ratio of 5:3:1, i.e., a kilog. of albumen costs five times, and a kilog. of fat three times, as much as a kilog. of carbon hydrate, we arrive by comparison of the nutritiousness of milk with other articles of diet, at the following results:—If we pay for 1 kilog. of milk, 15 pfennigs, for a mark we get 21·33 per cent. of nutriment; for 1 kilog. lard (bacon), 172 pfennigs, 16·08 per cent.; for 1 kilog. fatty cheese, 162 pfennigs, 14·32 per cent.; for 1 kilog. pork, 131 pfennigs, 14·01 per cent.; for 1 kilog. veal, 112 pfennigs, 10·33 per cent.; for 1 kilog. beef, 128 pfennigs, 9·11 per cent.; for 1 kilog. eggs, 200 pfennigs, 4·97 per cent.

"Now, if these facts are once known, milk as an article of diet will be more in demand, and the quantities no longer needed to make butter will find their way into the families where formerly pure butter was unknown, but where its substitute, cocoa-nut butter, has taken fast hold."—*Board of Trade Journal.*

CHEMICALS AND THE LONDON COUNTY COUNCIL.

At the meeting of the London County Council, which was held on December 17th at the Guildhall, the Earl of Rosebery in the chair, a report was brought up by Mr. Arthur Arnold, as chairman of the Main Drainage Committee, in which it was stated that the committee had received from the chemist his report, and that of Mr. Shoolbred, as to the experiments carried out by Mr. W. Webster at Crossness, on the electrical treatment of sewage, and they recommended that these reports be printed and distributed to the members of the Council, which was agreed to. The committee had received a report from the chemist as to the chemicals used during the past summer, from which they took the following extract:—"The quantities used at the Barking Outfall from 23rd May to 12th October were 1,313 tons of manganate, and 391 tons of sulphuric acid. At Crossness the quantities used from 23rd May to 6th October were 1,686 tons of

manganate and 664 tons of sulphuric acid, whilst there were used at the Storm Overflows during the same period 187 tons of manganate and 40 tons of sulphuric acid, the total being 3,197 tons 1 cwt. 3 qrs. 6 lb. manganate, and 1,096 tons 17 cwt. 2 qrs. 8 lb. acid, at a cost of 25,305*l.* 7*s.*" The report was adopted.—*Chemist and Druggist*.

RUSSIAN SODA.

A large works for the manufacture of soda is being erected in the Government of Jekaterinoslav, in Southern Russia. The output is estimated at 1,000,000 poods, or about 16,000 tons per annum. The extensive salt deposits in the vicinity of the factories are now being worked by a French company, who are under contract to supply the necessary salt to the new factory.—*Ibid*.

THE MONITEUR SCIENTIFIQUE.

The *Moniteur Scientifique* is to be, after all, continued by Dr. Quesneville's son Georges, a Fellow of the College of Pharmacy, and the pharmacist-in-chief of the Sainte Anne Asylum.—*Ibid*.

SULPHATE OF COPPER FOR SPANISH VINEYARDS.

Her Majesty's Consul at Barcelona reports to the Secretary of State for Foreign Affairs that notices have been published in the *Official Gazette* of the province by the "Provincial Deputation," signed by "E. Malaguer, president," to the effect that the "deputation" have decided to obtain in foreign markets where it is manufactured, a quantity of pure sulphate of copper for distribution to vine-growers in the province whose vineyards are attacked by mildew. Manufacturers are therefore invited to send samples, with quotation of prices, to the "deputation" at Barcelona, either direct or through their agents.—*London Chamber of Commerce (Information Circular)*.

PRUSSIA.

Our Berlin correspondent telegraphs that the *Warsaw Courier* states that the import into Prussia of cowhides and goatskins, bones, hoofs, and horns is again allowed on condition that they are dry, and sent in covered railway cars, and are transported to their place of destination without being reloaded.—*Daily News*.

CONCILIATION IN LABOUR DISPUTES.

The following important report has been presented to the London Chamber of Commerce by a committee appointed by the Council to consider and report upon the settlement of labour disputes. This report of the Labour Conciliation Committee has been provisionally adopted by the Council:—
December 12th, 1889.

Your committee has given its best attention to the subject of conciliation in settling labour disputes, which was referred to it by the Council. It has held eight meetings, and has also had interviews with many persons representing both capital and labour and possessing practical information on the subject. At the first meeting of the committee the chairman (Mr. S. B. Boulton) placed before it the draft proposals which accompany this report marked "A." These have formed at each meeting the subject of consideration by the committee, who have also had the benefit of the opinions upon them of many representative gentlemen who have come before it and expressed their views. These propositions have also been brought before various bodies of working men both at representative councils and at public meetings. So far as the committee, up to the present time, are able to form an opinion, the suggestions contained in the draft marked "A" seem to commend themselves both to its own members and to those who have appeared before it, or to whom they have been in other ways submitted, and they also seem to be practically adapted to carry out the objects in view. By means of correspondence the committee has also obtained some valuable information on the subject. In the mean time two threatened strikes have arisen, and representations have been officially made to the committee that the services of the Chamber might possibly, even at

this early stage, be of practical value in preventing such occurrences, and their consequent loss and injury. The committee therefore resolved to make an interim report to the Council, namely, to the effect that they ask its provisional approval of the chairman's propositions, and also for liberty, if the opportunity arises, to put them into practical operation as above suggested. Acting on the belief that these suggestions would be approved by the Council, and urged by the duty of doing everything in its power without delay to prevent any possible strike, the committee have already, on a request which has been made to them, offered facilities for mediation, viz., by offering to place the rooms of the Chamber at the disposal of the parties, and also indicating their willingness to assist in bringing about a settlement. Upon this special point therefore the approval of the Council is asked by the committee. Under powers to add to their number, the committee has invited Mr. E. H. Carbutt to join their body, and as regards the creation of the permanent committee contemplated by the draft propositions, the committee suggest that the selection of names should be referred to them to report upon at an early stage. Having regard to the similar functions of the Mansion House Committee and the desirability of their action being combined with that of the Chamber, the committee would recommend that the Lord Mayor, Sir James Whitehead, and Cardinal Manning be asked to join your committee, either individually or as representing the Mansion House Committee.

S. B. BOULTON, Chairman.

Committee.—Sir John Lubbock, Bart., M.P., Sir Albert Rollet, M.P., Sir Vincent Kennett-Barrington, R. K. Causton, Esq., M.P., Samuel Montagu, Esq., M.P., S. B. Boulton, Esq. (chairman), H. O. Arnold-Forster, Esq., E. H. Carbutt, Esq., and Kenrie B. Murray (secretary).

His Eminence Cardinal Manning, the Right Honourable Sir Henry Isaacs (Lord Mayor of London), and Sir James Whitehead, Bart., have now joined the committee.

LABOUR CONCILIATION COMMITTEE.

Proposed Recommendations to the Council.

It is advisable that the intentions of the Chamber relative to the settlement of future labour disputes should be made public through the medium of the Press and by public meeting, and that the co-operation of employers of labour and of trades unions and other representative bodies of the working classes should be earnestly solicited. It is inevitable that from time to time readjustments of the rates of labour should take place in sympathy with the fluctuating conditions of commerce and manufacturers, and the London Chamber of Commerce fully recognises the moral, as well as the legal, right of both employers and employed to combine for the purpose of protecting their respective interests. But the Chamber, in the interests of both classes, is most anxiously desirous that such adjustments should be brought about by amicable methods, and without the wasteful and calamitous occurrence of strikes and lock-outs, which in the case of the port of London have been proved by sad experience to cause a diminution in the volume of trade, upon the continuance and increase of which the toiling masses of this metropolis depend for their daily bread.

The committee recommends:—That a permanent committee, representative of both capital and labour, be appointed to deal with questions arising out of labour disputes in the port of London and in the metropolitan district. That this committee shall be composed of members of the council of this Chamber and of gentlemen not being members of the Chamber, but who may appear to possess such influence, authority, or experience as may be useful in promoting the settlement of such disputes. That when it shall be brought to the knowledge of the committee that a dispute as to the remuneration or other conditions of labour has arisen, or is likely to arise, the committee shall deliberate as to whether the said dispute is of sufficient importance to justify their intervention in the interest of the commerce or the manufactures of London. In the event of their decision being in the affirmative they shall be empowered on behalf of the Chamber—and that either upon their own initiative

or at the request of one or both of the parties concerned—to endeavour to promote a just, fair, and reasonable settlement; and that as a general rule the following course of procedure is recommended:

(a.) That they shall in the first instance invite both parties to the dispute to a friendly conference with each other; offering the rooms of the Chamber of Commerce as a convenient place of meeting. Members of the committee can be present at this conference, or otherwise, at the pleasure of the disputants.

(b.) That in the event of the disputants not being able to arrive at a settlement between themselves they shall be invited to lay their respective cases before the committee, with a view to receiving their advice, mediation, or assistance. Or, should the disputants prefer it, the committee would assist them in selecting arbitrators, to whom the questions at issue might be submitted for decision.

(c.) That the utmost efforts of the committee shall in the meantime, and in all cases, be exerted to prevent, if possible, the occurrence or continuance of a strike or lock-out until after all attempts at conciliation shall have been exhausted.

That the committee shall endeavour to promote the formation of councils of conciliation amongst the various trades of London, to be composed of employers and workmen, and it is suggested that such councils, if formed, might be affiliated to the London Chamber of Commerce.—*London Chamber of Commerce (Information Circular).*

BOARD OF TRADE RETURNS.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

18,528. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes, France. An improved method or process of and apparatus for the lixiviation of various materials. November 19.

18,529. W. T. Walker. Stills or apparatus for submitting liquids to the action of vapours or gases. Complete Specification. November 19.

19,002. J. E. Searles, jun. Improvements in method and apparatus for extracting the liquid of soluble constituents from disintegrated vegetable materials. Complete Specification. November 26.

19,070. E. W. Jacob and L. Watson. Filter for beer, spirits, wine, milk, and all other liquids. November 27.

19,096. T. Williams. Means and appliances for the production of pure carbonic oxide gas. November 27.

19,103. G. H. Lloyd, S. S. Lloyd, jun., and W. S. Sutherland. Improvements in the distribution and mixing of the inflammable gases or vapours and air utilised in gas or blow-pipe welding or heating, and in apparatus connected therewith. November 28.

19,222. E. Theisen. Apparatus for evaporating liquids. November 29.

19,488. A. L. Roek. Charging apparatus for blast and other furnaces, gas generators, kilns, ovens, and retorts. December 4.

19,533. S. Alley. Rotating furnaces for roasting or calcining ores or other substances. December 5.

19,607. S. Ralphs. Vessels or apparatus employed in concentrating sulphuric acid, and applicable for concentrating or distilling other acids or liquids. December 6.

19,906. W. H. Lonsdale. Cement for covering boilers, steam pipes, or vessels containing steam or heated water. December 11.

19,972. A. H. Hobson. Desiccating apparatus. December 11.

19,993. T. Smith. Boilers for utilising heat and making gas from the products of combustion. December 12.

20,049. D. Herman. Apparatus for concentrating solutions, drying substances, and like purposes. December 13.

20,147. A. J. Boulton.—From S. Touyrou. Machine for agglomerating and moulding sugar, brick, coal, or the like. December 14.

20,162. A. H. Hobson. Desiccating apparatus. December 14.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

18,948. V. Popp. Method and apparatus for utilising compressed air for production of cold. December 4.

19,057. E. Dobson. Apparatus for consuming or preventing smoke in furnaces. December 4.

1889.

83. W. Lawrence. Apparatus for distillatory and other purposes. November 27.

676. P. de Mol and A. Gerken. Filters. December 11.

1462. E. Dueret. Filtering apparatus. December 11.

1847. E. Harrison. Apparatus for softening and purifying water and prevention of incrustation in boilers. December 18.

2675. W. F. Goreham and M. Watson. Arrangement of mills for grinding cement, phosphates, &c.

10,521. G. H. Barrus. Apparatus for determining the quantity of moisture in steam. December 18.

16,583. A. Collingridge. Condensing apparatus. December 11.

17,084. V. W. Blanchard. Furnace and apparatus for generating heat. December 11.

17,432. L. Fromm. Thermometers. December 11.

17,505. J. Martinez-Ancira. Centrifugal pump. December 11.

17,686. R. Davidson and E. Emanuel. Apparatus for supplying a continuous and unvarying quantity of air to blast-furnaces, blow-pipes, &c. December 18.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

18,502. E. Fales. Improvements in and relating to the method of and apparatus for burning coal and other fuel in furnaces. Complete Specification. November 19.

18,543. J. E. Butterworth. An improvement in fire-lighters. November 20.

18,831. Kirkham, Hulett, and Chandler, Lim., and J. Chandler. Improvements in apparatus for separating or extracting tar and other impurities from gas. November 23.

18,970. J. Woodward. Improvements in apparatus, mechanism, and arrangements for the manufacture of gas from coal, cannel, or other suitable material. November 26.

19,121. W. G. Robinson. Improvements in apparatus for generating and burning gas from heavy oils or carbonaceous fluids. November 28.

19,256. G. C. Trewby. Improvements in the method of and means for charging gas retorts. November 30.

19,310. J. Watts. Improved firelighters. December 2.

19,449. G. Hargreaves, J. P. Seranton, and E. W. Porter. Improvements relating to the manufacture of gas and to apparatus therefor. Complete Specification. December 3.

19,539. W. P. Thompson.—From — Roadman. Improvements in apparatus for reducing and pulverising mineral fuel and other materials to powder, and for supplying the same mixed with air to furnaces. December 5.

19,572. W. Wood. Improvements in apparatus for the manufacture of illuminating or heating gases. December 5.

19,668. H. Brooke. Improvements in firelighters. December 7.

19,721. F. J. Jones. Improvements in the process of, and in apparatus for, the manufacture of illuminating gas. December 7.

19,763. F. Morris. An improved apparatus for charging inclined gas retorts. December 9.

19,993. T. Smith. See Class I.

20,031. W. Smith. Improvements in lighting by means of gas. December 12.

20,083. F. Siemens. Improvements in regenerative gas furnaces and gas producers. December 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,613. F. J. Jones and L. C. Alexander. Apparatus for manufacture of gas for illuminating, &c., and suitable for other purposes. December 4.

18,465. J. F. Cohen. Manufacture of artificial fuel. December 11.

18,682. W. J. Righton. Instantaneous water heaters. December 4.

1889.

995. W. B. Westlake. Apparatus for manufacture of perforated fuel. November 27.

1011. W. B. Westlake. Apparatus for manufacture of perforated fuel. November 27.

2964. H. Bate. Method and appliance for intensifying the light of oil, gas, &c. December 11.

15,426. M. A. Morse. Manufacture of gas, and apparatus therefor. November 27.

16,138. E. Tatham. Gases or gaseous mixtures for the production of light, heat, and power. December 4.

16,142. E. Tatham. Improvements in coal gas and like gases, and their manufacture. December 4.

16,646. D. H. Knapp. Manufacture of gas. December 4.

17,538. — Badlam. Apparatus for supplying air to carburettors and the outlet pipes thereof. December 18.

17,697. D. Irving. Hydraulic gas mains and valves connected therewith. December 11.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, &c.

APPLICATIONS.

18,599. A. J. Boulton. — From L. Zwillinger, Austria. Improved process and apparatus for the production of best hard charcoal together with the simultaneous recovery of acetic acid, wood spirit, tar, ammonia, gas. November 20.

18,823. L. Zwillinger. Improved process and apparatus for the production of best hard charcoal, together with the simultaneous recovery of acetic acid, wood spirit, tar, ammonia, and gas. November 23.

19,183. J. A. Yeadon and W. Adgie. Improvements in retorts or furnaces for the distillation of coal or other analogous purposes. November 29.

COMPLETE SPECIFICATION ACCEPTED.

1889.

2569. J. H. du Vivier. Apparatus for production of pyroligneous acid. December 18.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

18,517. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture or production of azo-colouring matters. November 19.

18,518. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co. Improvements in the manufacture of blue colours of the rosaniline group. November 19.

18,519. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co. Improvements in and connected with the manufacture and production of direct dyeing colouring matters for dyeing and printing. November 19.

18,901. C. Dreyfus. Improvements in the manufacture and production of colouring matters for dyeing and printing. Complete Specification. November 25.

18,927. H. H. Griffiths. An improved copying ink. November 26.

19,655. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co., Germany. Improvements in the manufacture and production of dyestuffs for dyeing and printing. December 6.

19,729. H. H. Lake.—From A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matter. December 7.

20,020. K. E. Klimosch and F. C. Weiss. A new manufacture of colouring matter for dyeing. December 12.

20,047. S. A. Sadler and A. Wolf. Improvements in the manufacture of alizarine and the alkaline salts of alizarine sulphonic acid. December 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

1803. J. Frost. Method and means for concentrating solutions for the production of dyes, &c. December 11.

2499. O. N. Witt. Production of new azo dyes. December 18.

2635. R. Gnehm. New colouring matter, and its method of manufacture. December 18.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

18,852. T. Burrows. Improved method of treating flax yarns. November 23.

18,853. T. Burrows. A novel method of preparing flax and hemp. November 23.

18,925. A. Mitscherlich. A method of and apparatus for manufacturing threads from wood. November 25.

18,932. K. T. Sutherland and G. Esdaile. An improved method of treating vegetable fibres so that they will spin more easily, and make stronger yarn, thread, or strand. November 26.

19,733. E. T. Truman. Improvements in the treatment of hemp, flax, jute, cotton, and other substances in order to preserve the same. December 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,574. H. Sauvage. Conversion of jute textiles. December 4.

1889.

2570. J. H. Du Vivier. A new composition called "artificial silk," for the production of threads, and for coating threads, fabrics, &c., and apparatus for manufacturing the said composition. December 18.

2571. J. H. Du Vivier. Apparatus for manufacturing textile threads from viscous or semi-fluid matters. December 18.

13,127. W. Latimer. Fibre from the leaves of needles of *Pinus Australis* and other coniferous trees. December 4.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

18,718. P. Thomas. Improvements in machinery or apparatus for bleaching yarn. November 22.

18,719. P. Thomas. Improvements in machinery or apparatus for bleaching and washing woven fabrics. November 22.

18,859. F. B. Gouty. An improved process and means for dyeing yarns and fibrous substances. November 25.

18,973. L. Weldon. Improvements in machines for dyeing cotton and analogous materials. Complete Specification. November 26.

19,408. C. Weber-Jacquel. Improved apparatus for dyeing, cleansing, bleaching, and drying yarn in cops or in similar condition. December 3.

19,490. L. Schreiner. A new or improved method of dyeing aniline black. December 4.

19,863. C. Corron. Improved apparatus for dyeing textile fabrics. December 10.

20,026. F. A. Eggleton. The manufacture of an improved medium for staining or colouring various substances. December 12.

20,064. R. Holliday. Improvements in producing azo colours on cotton or other vegetable fibres. December 13.

20,155. P. Rhodes. Improvements in apparatus for dyeing wool, wool tops, cotton, and other fibrous substances. December 14.

COMPLETE SPECIFICATION ACCEPTED.

1888.

18,904. J. Cowan. Indigo dyeing. November 27.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

18,701. P. Naef.—Partly communicated by G. Lunge, Switzerland. Improvements in treating impure hydrochloric acid or mixtures of gases containing hydrochloric acid for the manufacture of chlorine. November 22.

18,742. L. T. Thorne, E. Luck, and Brin's Oxygen Company, Limited. Improvements in the manufacture of vinegar. November 22.

18,904. W. P. Thompson.—From E. de Lom de Berg, Belgium. Process for the manufacture of picric acid by crude phenols. Complete Specification. November 25.

19,144. R. Fullarton. Process for the separation of carbonate of lime from phosphatic minerals. November 28.

19,225. T. Wilton and G. Wilton. Improvements in or connected with the manufacture of sulphate of ammonia and apparatus therefor. November 29.

19,573. H. L. Pattinson, jun. Improvements in the manufacture of oxides of the alkaline earths, and in apparatus for the purpose. December 5.

19,592. F. Ellershansen. Improvements in the manufacture of soda. December 5.

20,078. A. Martignier. An improved process for the extraction of the tartrate of lime contained in lyes and other tartarous matters, and its transformation into cream of tartar or into tartaric acid. December 13.

20,135. J. E. J. Johnson. Improvements in the manufacture of acetic acid and soluble acetates. Complete Specification. December 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,528. J. Barrow. Treating gases and recovering sulphur from sulphuretted hydrogen evolved in manufacturing processes. December 4.

18,574. E. Solvay. Manufacture of chlorine and chloride of lime, and apparatus therefor. November 27.

1889.

1885. C. Roth. Manufacture of nitrate of ammonia and sulphates, chlorides, and carbonates of potassium and sodium. December 11.

2310. T. Parker and E. Robinson. Production of chlorine and sulphate of soda. December 18.

2383. T. Parker and E. Robinson. Manufacture of cyanogen compounds from sulphocyanides. December 18.

12,451. A. W. Wahlenberg and J. A. Wahlenberg. Producing ammonium nitrate. December 18.

17,348. J. E. J. Johnson. Manufacture of acetic acid, soluble acetates, and calcium sulphites. December 18.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

18,621. J. Middleton. Improvements in the mode of and apparatus for producing upon earthenware imitations of granite or the like. November 21.

18,951. W. J. Hague. Improvements in and relating to kilns for burning clay goods, furnaces and like fires, and in utilising the heat from gas producers in connexion therewith. November 26.

19,090. J. B. Shelley and P. Shelley. Improvements in the manufacture of decorated earthenware, porcelain, glass, and the like. November 27.

19,101. T. W. Gimson, W. Kent, and T. Banks. Improved means for preparing the prints used in printing potters' ware, and apparatus therefor. November 28.

19,312. J. Whitehouse. Improvements in kilns and furnaces for heating and burning bricks, pottery, and the like, and other purposes. December 2.

19,734. D. Rylands. Improvements in the manufacture by machinery of glass tubes, sheet glass, and other glass ware. December 9.

19,744. G. A. Marsden. Improvements relating to the manufacture of tiles, bricks, or the like articles, having ornamented or decorated surfaces. Complete Specification. December 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

1198. A. Ramsden. Method and machinery for making earthenware pipes. November 27.

2611. T. Davidson. Manufacture of articles of pressed glass. December 11.

6446. J. E. Matthewson. — From B. C. Tilghman. Ornamentation of glass, and apparatus therefor. November 27.

16,536. H. Hall. Tiles for lining walls. November 27.

16,683. E. Leak and H. Aynsley. Apparatus for supporting pottery ware while being fired. November 27.

16,742. E. Leak and H. Aynsley. Means for supporting pottery ware while being baked or fired. November 27.

17,105. J. B. Curtis and J. W. Mackintosh. Manufacture of hollow ware from glass, &c. December 4.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

18,187. H. H. Lake. — From G. M. Fiske, United States. Improvements relating to the construction of brickwork. Complete Specification. November 19.

18,493. H. H. Lake. — From G. M. Fiske. Improvements in bricks. Complete Specification. November 19.

18,744. C. D. Abel. — From The Actien Gesellschaft für Asphaltirung und Dachbedeckung vorm. J. Jeserich, Germany. An improved manufacture of artificial stone for building and other purposes. November 22.

18,898. C. Hucker. — From F. Rulf, Germany. Process for producing artificial stone for shelling and hulling grain. November 25.

18,911. P. de Kristoffovitch. Improved manufacture of artificial granite. Complete Specification. November 25.

19,092. W. S. Akerman. Improvements in boilers for utilising the waste heat of kilns or ovens for burning cement, lime, bricks, and other materials. November 27.

19,586. C. Smith. — From P. M. Elkjær. Improvements in and in the manufacture of imitation marble, stone, and mosaic. December 5.

19,601. J. S. Palmer. Plastic wall and ceiling covering composition in ornamental relief. December 6.

19,744. G. A. Marsden. See Class VIII.

19,818. H. A. Walker, A. C. Ponton, B. L. Mosely, and C. Chambers. A process for utilising waste or artificial cryolite in the manufacture of artificial stone. December 10.

20,107. W. S. Akerman. Improvements in and relating to kilns or ovens for burning bricks, lime, cement, or other materials. December 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,363. J. Hargreaves, T. Robinson, and J. Hargreaves. Manufacture of cement, and apparatus therefor. November 27.

1889.

2121. G. A. Wright. An improved block, tile, or slab for building and other purposes. December 11.

14,733. D. Nicoll. Waterproof slabs and blocks. November 27.

16,941. H. D. Blake. Block paving. December 4.

17,961. J. C. Fell. — From G. Phillips. Coating exposed wooden structures or timbers. December 18.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

18,581. J. Shears. Improvements in processes for recovering tin from solutions of tin oxides. November 20.

18,660. C. Davy. Improvements in or connected with apparatus for heating and forging large masses of metal. November 21.

18,710. D. W. Cuthbert. Improvements in obtaining gold and silver from ores. November 22.

18,728. A. S. Ramage. Improvements in the manufacture or purification of steel or iron. November 22.

18,985. C. A. Piat. Improvements in metallurgical furnaces. November 26.

19,145. E. A. Herberitz. Improvements in smelting furnaces. Complete Specification. November 28.

19,148. J. C. Bull. Improvements in the manufacture of metallic alloys and compounds, and in apparatus therefor. November 28.

19,287. R. Stone. Improvements in refining metals of all kinds and other substances, such improvements also effecting the consumption of smoke. November 30.

19,306. J. E. Bennett. Improvements in the treatment of metallic chlorides for extraction of metals therefrom. December 2.

19,333. W. Sellar. Improvements in the method of, and converters or machinery for, the manufacture of iron or steel. December 2.

19,334. W. L. Wise. — From B. Natusch, Germany. Process for the production of solutions of nickel and cobalt from ores or products containing these metals. Complete Specification. December 2.

19,384. T. Twynam. Improvements in the manufacture of steel. December 3.

19,501. C. Rahache. Improvements in and connected with the extraction or reduction of zinc from ores or compounds, and in apparatus therefor. December 4.

19,588. C. A. Faure. Improvements in the manufacture of ferro-aluminium, applicable also to other purposes. December 5.

19,621. D. Dumes and T. K. Rose. An improved process or means for extracting precious metals from their ores. Complete Specification. December 6.

19,622. D. Dumes and T. K. Rose. Improvements in machinery or apparatus for extracting precious metals from their ores. Complete Specification. December 6.

19,652. T. H. Johns. Improvements in the manufacture of tin andterne plates, and in the apparatus therefor. December 6.

19,653. T. H. Johns. Improved means and apparatus for coating sheet iron (galvanising) and finishing same. December 6.

19,672. C. Gelstharp. Improvements connected with means and apparatus for separating metals from ores or compounds containing metals. December 7.

19,687. T. Teague. Improvements in the utilisation of the alloys of tin and tin oxides, and separating same. December 7.

19,759. J. T. Penny and W. H. Richardson. An improved machine for triturating and amalgamating gold and silver bearing and other ores. Complete Specification. December 9.

19,859. A. P. Rushforth. Utilisation of waste gases and superfluous heat in cupola and blast furnaces, and in apparatus employed in the manufacture of iron and steel and the smelting of metals. December 10.

19,865. E. P. Peyton. Improvements in cleaning sheets of wrought iron, iron wire, and articles of wrought iron, and in utilising the waste products obtained, and in apparatus to be employed in conducting the said cleaning and utilising processes. December 10.

19,890. H. Aiken. Casting ingots, billets, &c. Complete Specification. December 10.

19,941. J. A. H. T. Rauff. An improved process and apparatus for the continuous extraction of gold and silver from substances containing the same, by the agency of chlorine. Complete Specification. December 14.

20,017. R. E. Shill. Improvements in apparatus for separating precious metals from ores or materials containing them. December 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,858. D. Q. Brin and A. Brin. Extracting iron from its ore, and purifying iron. December 4.

18,004. A. Clement-Conti. Apparatus for treating auriferous sand and other matters containing free gold. December 4.

18,493. R. A. Hadfield. Cutting hollow steel and other steel shells, and apparatus therefor. November 27.

18,506. R. A. Hadfield. Manufacture of hollow steel and other steel shells. November 27.

1889.

77. E. A. Billault. Manufacture of jewellery and ornamental objects from sulphide of silver. November 27.

812. R. A. Hadfield and A. G. M. Jack. Manufacture of cast steel shells. November 27.

868. J. Hart. Method of heating plates of steel, or any other metal. November 27.

1380. J. Müller. Miners' safety lamps. November 27.

1683. C. A. Caspersson. Determining the temper of iron and steel. December 11.

1987. J. Ward. Manufacture of compound plates of iron and steel. December 11.

1989. H. Y. Castner. Production of pure double chlorides of aluminium. December 11.

2369. L. Roberts, J. Jones, and The Moor Steel and Iron Co., L^{im}. Method and apparatus for charging pig iron and scrap, &c., into steel and open-hearth furnaces. December 18.

2456. W. Hawdon. Apparatus for removing molten slag or scoria from furnaces. December 18.

5351. J. Jones, C. Vernon, E. Holden, and R. Bennett. Making box piles for the production of blooms and bars, &c., of iron or steel, or mixtures thereof. December 18.

9289. W. F. M. McCarty, W. H. Ashton, and H. D. Wallbridge. Process and apparatus for producing steel direct from the ore. December 11.

13,986. J. Hansen. Apparatus used in the smelting of cast-iron borings, turnings, and shavings. December 18.

16,396. W. P. Thompson. — From J. B. Brewster. Amalgamators for extracting precious metals from impurities combined with them. December 11.

16,474. R. F. Ludlow. Manufacture of iron and steel. December 4.

17,065. F. D. Taylor. Improvements in moulding or casting, and in moulds therefor. December 4.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

18,365. J. B. Entz and W. A. Phillips. Improvements in and connected with plates for primary and secondary batteries. Complete Specification. November 18.

18,481. C. Payen. Improvements in secondary or storage batteries. Complete Specification. November 19.

18,680. H. Hauser. Improvements in the construction of dynamo-electric machines. November 21.

18,700. T. W. Watson and A. H. Watson. Improvements in connexion with electric battery cells. November 22.

18,755. A. Reckenzum. Improvements in the manufacture of plates for use in secondary batteries or electrical accumulators. November 22.

18,953. G. Macaulay-Cruikshank. — From W. A. Johnson and J. N. Smith, Canada. An improved electrode for secondary batteries or accumulators. Complete Specification. November 26.

18,966. O. A. Enholm. Improvements in primary or galvanic batteries. Complete Specification. November 26.

18,989. W. F. Smith. Improvements in secondary or storage batteries. Complete Specification. November 26.

19,080. H. T. Cheswright. An improved construction of plates for secondary or other voltaic batteries. November 27.

19,129. C. R. Bone. — From H. Meinecke, jun., Germany. Improvements in electric dry batteries. November 28.

19,335. H. Merryweather. Improvements in voltaic batteries. December 2.

19,491. G. Philippart. Improvements in electric batteries. December 1.

19,813. H. Wernley and H. Foster. Improvements in the methods and apparatus employed in the heating, melting, and working of metals, alloys, and metalloids by the application of electric currents. December 10.

19,857. Sir C. S. Forbes, Bart. Improvements in secondary battery elements. December 10.

19,861. C. H. Logan. Improvements in secondary batteries. Complete Specification. December 10.

19,883. J. K. Pumpelly and F. D. Thomason. Improvements in electrical secondary batteries. Complete Specification. December 10.

19,892. H. E. Fowler. Improvements in machines or apparatus for welding metal by means of electricity. Complete Specification. December 10.

19,899. W. P. Thompson.—From M. W. Parrish, United States. Improvements in or relating to electric batteries. December 10.

20,106. G. L. Hille. Improvements in and connected with electric batteries. December 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,445. Marino. Extraction and electro deposition of aluminium and aluminium alloys. December 18.

1889.

1535. J. A. Timmis. Construction and working of dynamos. December 11.

1571. T. B. Saunders. Galvanising iron and steel. December 4.

1673. G. Philippart. Secondary batteries. December 4.

5816. W. E. Langdon. Secondary batteries. November 27.

16,036. W. E. Irish. Galvanic batteries. November 27.

16,241. H. H. Carpenter. Electric storage batteries. December 11.

19,403. C. W. Kiamins and T. Craig. Improvements in the separation of fatty or greasy matters from the washwaters of wool washing or scouring establishments. December 3.

19,615. C. R. Hingworth. Improvements in soaps. December 6.

19,922. G. T. Cannon. A compound medical animal soap. December 11.

19,948. W. Grills and M. Schroeder. An improved process for the extraction of fats and oils from substances containing the same, by means of sulphurous acid. Complete Specification. December 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,852. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. Purification of fatty substances, and apparatus therefor. November 27.

18,857. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. Purification of fatty substances, and apparatus therefor. December 1.

1889.

1142. H. Guthrie. Manufacture of oil cake, and expression of oil from oleaginous seeds or kernels. November 27.

1501. W. Mc Lay. Lubricants. November 27.

17,741. W. Hepworth-Collins and W. J. Smith. Dry soap or washing powder. December 11.

17,742. W. Hepworth-Collins and W. J. Smith. A disinfectant and detergent dry soap or washing powder, or essence. December 11.

18,046. C. H. Robinson. Thickening linseed oil. December 18.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

18,592. J. Y. Johnson.—From L. Genevois, Italy. Improvements in the treatment or preparation for consumption of soft soaps and other like materials. Complete Specification. November 20.

18,628. L. T. Thorne and Brin's Oxygen Company, Limited. Improvements in the oxidation and thickening of oils for use in the manufacture of paints, varnishes, linoleum, floor cloth, or for other purposes to which thickened or oxidised oils are applicable. November 21.

18,988. W. H. Lever, J. D. Lever, and E. G. Scott. Improvements in extracting oil or grease. November 26.

19,158. P. Heinz. A new or improved method for sweetening margarine butter, and other oils and fats. Complete Specification. November 28.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

18,429. H. Joyce and W. Skade. A polish composition for leather and other surfaces. November 18.

18,628. L. T. Thorne and Brin's Oxygen Company, Limited. See Class XII.

18,642. C. Lohusen and C. Fenerlein. Improved process for the separation of an extract "Lanoresin" or gum resin from the waste waters of wool washing and combing mills, and for the production of the same in a pure condition. November 21.

18,706. R. F. Flynn. The novel application of pitch or oil residue in the manufacture of a floor covering to be known as "Corkoline carpet." November 22.

18,921. W. Feld. Improvements in the manufacture of permanent white and alkaline carbonate or alkaline bicarbonate. November 25.

19,343. G. Bischof. A process for the manufacture of white lead. December 2.

19,910. J. E. Wood. The improvement of "sublimed" white lead. December 11.

20,010. J. H. Bath. A pure boot blacking powder. Complete Specification. December 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

1578. R. Stone. Manufacture of paints and pigments. December 11.

12,844. T. H. Wright. Composition for waterproofing, &c. December 4.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

18,503. R. W. Johnson. Improvements in and relating to plastics, more especially designed for imparting to glue a permanent elasticity, and adapted to be used for various purposes. Complete Specification. November 19.

18,730. W. P. Thompson.—From C. Heepe, Prussia. New or improved flexible material applicable as a substitute for wood or leather, and process of making the same. November 22.

COMPLETE SPECIFICATION ACCEPTED.

1889.

17,436. H. J. Haddan.—From J. Landini. Process for discolouring tannic acid solutions. December 11.

XV.—AGRICULTURE AND MANURES.

APPLICATIONS.

18,677. W. B. Kemshead. Improvements in the treatment of sewage and sewage matters, and in the production of fertilising products therefrom. November 21.

18,918. E. Saxl and H. Saxl. Improvements in fertilisers. Complete Specification. November 25.

19,225. T. Wilton and G. Wilton. See Class VII.

20,076. H. Fewson. An improved method of nitrogenising suitable substances or bodies. December 13.

COMPLETE SPECIFICATION ACCEPTED.

1889.

1710. W. Riddiough. Method of treating certain refuse matter to increase its fertilising properties. December 4.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

18,516. F. M. Lyte. Improvements in extracting iron from syrups which may have become contaminated with it, and from the substances used in its treatment. November 19.

19,728. W. Thomson, J. Mylne, and J. B. Allott. Improvements in apparatus for the expression of juice from sugar cane. Complete Specification. December 7.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

18,391. H. Stockheim. New or improved process of filtering beer or other liquids and apparatus therefor. November 18.

19,003. H. T. Brown, G. H. Morris, and E. R. Moritz. An improvement in the manufacture of beer. November 26.

19,376. J. F. H. Gronwald and E. H. C. Oehlmann. Improved process for treating beer and making it keep permanently in good condition. Complete Specification. December 3.

19,772. J. Torbitt. Improvements in the manufacture of alcoholic liquids from vegetable products. December 9.

19,996. W. Spilker, H. Bendel, M. Hahn, and C. Lüewe. A new method of killing microbe-like minute living organisms, such as yeast cells, bacilli, and the like, contained in wines, alcoholic and other similar liquors. Complete Specification. December 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1889.

83. W. Lawrence. See Class I.

770. H. E. Sorel. Treatment of commercial alcohols. December 18.

962. A. Malzy. Alcoholic beverages. December 4.

1942. G. G. Cave and J. H. Howell. Apparatus for promoting circulation and aëration of brewers' wort. December 11.

16,947. A. de Méritens. Rectifying or ageing alcohol or alcoholic liquors, &c. by electricity. November 27.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

18,281. E. Edwards.—From A. Seidensticker, Germany. An improved method of and apparatus for preserving milk. November 30.

19,882. H. Barotte. An improved process and apparatus for the production of dry extract of coffee. December 10.

B.—Sanitary Chemistry.

18,677. W. B. Kemshead. Improvements in the treatment of sewage and sewage matters, and in the production of fertilising products therefrom. November 21.

18,946. J. W. Calvert and J. Chaffer. Precipitating and filtering crude sludge running away from tanneries, factories, dye works, or from any other source, and putting it portable, without the aid of mechanical power, and without adding any solids. November 26.

19,638. R. Hannam. Improvements in the sanitary treatment of drains, and in materials to be used therefor. December 6.

C.—Disinfectants.

18,460. M. Hargreaves. Improvements in disinfectants and antiseptics. November 19.

18,512. J. Price. Improvements in disinfectants and deodorisers. November 19.

19,309. G. T. Moody and F. W. Streatfield. A new method of producing and liberating aerial or gaseous disinfectants. December 2.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1888.

18,079. G. D. Wheaton. Means for the preservation of perishable substances. December 4.

19,009. J. L. Johnston. Preparation and combination of animal substances for use as food. December 11.

1889.

1033. W. G. Pursell. Treating and preserving fish. November 27.

17,380. R. Denby. Preparation of rennet powder for cheese making. December 11.

B.—Sanitary Chemistry.

1888.

17,962. J. Wilkinson and J. B. Allott. Apparatus for treating refuse. December 1.

1889.

1144. C. F. Gower. Apparatus for extracting the solid suspended matter from sewage or other liquid. December 11.

1628. J. Bradbury. Construction of destructor furnaces, and means for heating them for burning noxious vapours, refuse, &c. December 4.

C.—Disinfectants.

1889.

11,974. F. G. A. Roberts, A. Shearer, and W. B. Giles. Preparation of antiseptics. December 4.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

19,903. W. P. Thompson.—From C. Rolland, France. Improvements in the preparation or treatment of paper for producing copies of drawings or the like by the action of light. December 10.

19,587. C. F. Cross and E. J. Bevan. Some new applications of cellulose. December 5.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,779. J. Von der Poppenburg. Manufacturing papers coated with metallic foil. November 27.

18,003. F. Salomon and H. Brungger. Protecting apparatus used in the manufacture of sulphite cellulose. December 11.

1889.

1433. R. Hamilton and J. C. Hamilton. Cleansing paper-making materials and other fibrous matters. November 27.

1834. C. Ramsey. Manufacture and bleaching of wood and other pulps, and apparatus therefor. December 4.

2439. D. M. Watson and T. T. M. Lumsden. Apparatus for manufacture of paper. December 18.

17,141. D. H. Ferguson. Process for manufacturing articles from pulp. December 4.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

18,434. G. Luman. So preparing the disulphones, such as sulphonal, tetronal, trional, &c., and afterwards enclosing the powders thus prepared in gelatinous or membranous capsules capable of containing them so as to render them soluble and consequently assimilative, active and certain. November 19.

18,990. W. H. Lever, J. D. Lever, and E. G. Scott. Improvements in the manufacture of tetrachloride of carbon. November 26.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

18,547. B. Jumeaux. A new or improved compound for use in photography. November 20.

19,205. J. B. Payne.—From F. C. Binns, New Zealand. An improved process or means for giving a matt surface to albuminised silver paper photographs or prints. November 29.

19,508. W. E. Debenham. Improvements in producing magnesium flash light. December 5.

COMPLETE SPECIFICATION ACCEPTED.

1889.

741. A. F. Y. Schwartz and F. H. Mercklin. Production of films sensitive to light, and of materials for assisting or continuing the effect of light on photographic films. December 4.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

18,738. A. Martin. Improvements in percussion fuses for explosive projectiles. November 22.

19,673. L. Davies and J. Turnbull, jun. Improvements in machinery for making gunpowder pellets or compressed cartridges. December 7.

19,674. L. Davies. Improvements in treating gunpowder pellets. December 7.

19,935. A. T. Cocking. Improvements in treating and using explosives whereby the flame produced is controlled and quenched.

19,971. A. Martin. Improvements in percussion fuses for explosive projectiles. December 11.

20,013. F. E. Spiller. Improved means for igniting lucifer matches. December 12.

20,104. The Roburite Explosives Co., Lim., C. Roth, and W. J. Orman. Improvements in the treatment or preparation of nitrate of ammonium. December 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

17,631. H. Ritter von Dahmen. Manufacture of nitro-glycerin and dynamite. November 27.

1889.

2078. O. Inray.—From F. C. Glaser. Granulating and glazing gelatinous explosives. December 11.

13,907. H. H. Leigh.—From La Compagnie Forat. Apparatus and process for the manufacture of nitro-glycerin. December 4.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATIONS.

18,856. A. W. Gerrard. Estimating the quantity of glucose or grape sugar in fluids. November 25.

19,470. A. T. Rapkin. Improvements in pyrometers. December 4.

19,669. R. M. Douglas. Improvements in Sykes' hydrometer. December 7.

COMPLETE SPECIFICATION ACCEPTED.

1889.

15,800. H. Cortland. Thermostats. November 27.
